FortiOS™ Handbook

01-5410-506052-20180827

TABLE OF CONTENTS

Chapter 1 - What's New for FortiOS 5.4 ..... **47**

What's New in FortiOS 5.4.6 48
What's New in FortiOS 5.4.4 50
What's New in FortiOS 5.4.3 50
What's New in FortiOS 5.4.2 51
Cooperative Security Fabric (CSF) 55
Fortinet Cookbook Recipe Collection 55
Cooperative Security Fabric Menu 55
CSF FortiView Dashboards 55
FortiTelemetry 56
External Security Devices 56
Policy Learning Mode 58
FortiView 61
New Consoles 63
Cloud Access Security Inspection (CASI) 72
Cloud Access Security Inspection (CASI) 72
Managed FortiSwitch 75
FortiGate CLI support for FortiSwitch features (on non-FortiLink ports) 79
Changing the FortiGate's inspection mode to flow or proxy 81
GUI Refresh 86
New options for editing policies from the policy list 87
Changing the GUI theme 88
Full screen mode 88
Edit in CLI 88
Display the hostname on the GUI login page (129248) 89
Other GUI changes(129248) 89
GUI favorite and search (307478) 89
DNS Filter 91
FortiSandbox Integration 94
Connecting to a FortiSandbox 94
Pushing malicious URLs to Web Filtering 95
FortiSandbox Dashboard in FortiView 96
Pushing signatures to AntiVirus database 97
FortiClient Monitoring and Quarantine 98

Traffic Shaping Policies 100
New button added to "Clone" Shapers 102
WAN link load balancing 103
WAN links 103
Priority rules 106
Estimated Bandwidth 107
Status checking or health checking 108
Virtual Wire Pair 110
Adding a virtual wire pair 110
Adding a virtual wire pair firewall policy 111
Authentication 113
PCI DSS compliance 119
Device identification 121
Diagnose command changes 124
Explicit web proxy 130
Firewall 134
FortiGate VM 140
Hardware acceleration 143
High Availability 146
IPsec VPN 149
IPv6 155
Load balancing 158
Logging and Reporting 163
Maximum values changes 167
Networking 168
RFCs supported by FortiOS 5.4 181
Security Profiles 183
Session-aware Load Balancing (SLBC) 199
SSL VPN 200
System 203
VDOMs 216
WAN Optimization 218
WiFi 221
Chapter 2 - Getting Started 233
Differences between Models 233
Entry-level models 233
Quick installation using DHCP 234
CLI-only features 235
Installation 236
NAT/Route Mode vs. Transparent Mode 237
Setup Wizard 238
Installing a FortiGate in NAT/Route mode 239

Using a Virtual Wire Pair ... 243
Troubleshooting your FortiGate Installation ... 245
Using the GUI ... 247
Connecting to the GUI ... 248
Menus ... 249
Dashboard ... 251
Feature Select ... 259
Tables ... 260
Text Strings ... 261
Using the CLI ... 262
Connecting to the CLI ... 262
Command syntax ... 267
Sub-commands ... 270
Permissions ... 274
Tips ... 275
FortiGate LED Specifications ... 283
Sample FortiGate Faceplates ... 283
LED Status Codes ... 284
About Alarm Levels ... 285
LED Status Codes for Ports ... 285
FortiGate Inspection Mode ... 286
A Guide to Using the Entry Level Models ... 291
Disabling the GUI lite on 30D models ... 291
Basic Administration ... 291
Registration ... 292
Passwords ... 293
Firmware ... 294
Configuration Backups ... 304
FortiGuard ... 310
FortiCloud ... 319
Next Steps ... 321
Best Practices ... 321
The Fortinet Cookbook ... 321
The Fortinet Video Library ... 321
The FortiOS Handbook ... 321
Chapter 3 - Advanced Routing ... 323
What's new for networking in FortiOS 5.4 ... 324
Virtual Wire Pair ... 324
Adding a virtual wire pair ... 324
Adding a virtual wire pair firewall policy ... 325
WAN Link Load Balancing ... 326
WAN links ... 326

Priority rules 329
Estimated Bandwidth 330
Status checking or health checking 331
New features in 5.4.1 333
New features in 5.4.0 339
Advanced Static Routing 345
Routing concepts 345
Static routing tips 360
Policy routing 361
Transparent mode static routing 364
Static routing example 365
Dynamic Routing Overview 373
What is dynamic routing? 373
Comparison of dynamic routing protocols 377
Choosing a routing protocol 382
Dynamic routing terminology 383
IPv6 in dynamic routing 388
Routing Information Protocol (RIP) 389
RIP background and concepts 389
Troubleshooting RIP 401
Simple RIP example 405
RIPng — RIP and IPv6 420
Border Gateway Protocol (BGP) 426
BGP background and concepts 426
Troubleshooting BGP 438
Dual-homed BGP example 443
Redistributing and blocking routes in BGP 456
Open Shortest Path First (OSPF) 463
OSPF Background and concepts 463
Troubleshooting OSPF 475
Basic OSPF example 477
Advanced inter-area OSPF example 489
Controlling redundant links by cost 500
Intermediate System to Intermediate System Protocol(IS-IS) 503
IS-IS background and concepts 504
How IS-IS works 504
Troubleshooting IS-IS 510
Simple IS-IS example 513
Network layout and assumptions 514
Expectations 515
CLI configuration 515
Verification 517

Troubleshooting 520
Chapter 4 - Authentication 521
Whats New in FortiOS 5.4 522
FortiOS 5.4.1 522
FortiOS 5.4.0 523
Introduction to authentication 528
What is authentication? 528
Methods of authentication 528
Types of authentication 530
Single Sign-On authentication for users 533
User's view of authentication 534
FortiGate administrator's view of authentication 534
General authentication settings 535
Authentication servers 537
FortiAuthenticator servers 537
RADIUS servers 537
LDAP servers 543
TACACS+ servers 551
POP3 servers 552
SSO servers 553
RSA ACE (SecurID) servers 555
Users and user groups 560
Users 560
User groups 574
Managing Guest Access 580
Configuring guest user access 580
Guest access in a retail environment 582
Configuring authenticated access 586
Authentication timeout 586
Password policy 587
Authentication protocols 588
Authentication in Captive Portals 589
Authentication in security policies 589
Authentication replacement messages 590
VPN authentication 601
Captive portals 606
Introduction to Captive portals 606
Configuring a captive portal 606
Customizing captive portal pages 608
Certificate-based authentication 614
What is a security certificate? 614
Certificates overview 615

Managing X.509 certificates 618
Configuring certificate-based authentication 626
Support for per-VDOM certificates 628
Example — Generate a CSR on the FortiGate unit 629
Example — Generate and Import CA certificate with private key pair on OpenSSL 630
Example — Generate an SSL certificate in OpenSSL 631
Single Sign-On using a FortiAuthenticator unit 634
User's view of FortiAuthenticator SSO authentication 634
Administrator's view of FortiAuthenticator SSO authentication 634
Configuring the FortiAuthenticator unit 635
Configuring the FortiGate unit 636
Configuring the FortiClient SSO Mobility Agent 637
Viewing SSO authentication events on the FortiGate unit 637
Single Sign-On to Windows AD 638
Introduction to Single Sign-On with Windows AD 638
Configuring Single Sign On to Windows AD 638
FortiOS FSSO log messages 643
Testing FSSO 644
Troubleshooting FSSO 644
Agent-based FSSO 646
Introduction to agent-based FSSO 646
FSSO NTLM authentication support 652
Agent installation 655
Configuring the FSSO Collector agent for Windows AD 660
Configuring the FSSO TS agent for Citrix 672
Configuring FSSO with Novell networks 673
Configuring FSSO Advanced Settings 675
Configuring FSSO on FortiGate units 680
FortiOS FSSO log messages 686
Testing FSSO 688
Troubleshooting FSSO 688
SSO using RADIUS accounting records 691
User's view of RADIUS SSO authentication 691
Configuration Overview 691
Configuring the RADIUS server 691
Creating the FortiGate RADIUS SSO agent 692
Defining local user groups for RADIUS SSO 693
Creating security policies 694
Example: webfiltering for student and teacher accounts 695
Monitoring authenticated users 698
Monitoring firewall users 698
Monitoring SSL VPN users 698

Monitoring IPsec VPN users 699
Monitoring users Quarantine 699
Examples and Troubleshooting 701
Firewall authentication example 701
LDAP Dial-in using member-attribute example 707
RADIUS SSO example 709
Troubleshooting 716
Chapter 5 - Best Practices 718
Introduction 718
General Considerations 718
Customer service and technical support 718
Fortinet Knowledge Base 718
System and performance 720
Performance 720
Shutting down 720
Migration 721
Information gathering 721
Object and policy migration 721
Testing and validation 721
Going live and obtaining feedback 722
Adding new services 722
Environmental specifications 723
Grounding 723
Rack mounting 723
Firmware 725
Firmware change management 725
Performing a firmware upgrade 728
Performing a firmware downgrade 729
Performing a configuration backup 729
Security Profiles (AV, Web Filtering etc.) 732
Firewall 732
Security 732
Authentication 733
Antivirus 733
Antispam 733
Intrusion Prevention System (IPS) 733
Email filter 734
URL filtering 734
Web filtering 735
Patch management 735
Policy configuration 735
Networking 737

Routing configuration 737
Advanced routing 737
Network Address Translation (NAT) 738
Transparent Mode 738
Using Virtual IPs (VIPs) 738
FGCP High Availability 739
Heartbeat interfaces 739
Interface monitoring (port monitoring) 740
WAN Optimization 741
Virtual Domains (VDOMs) 743
Per-VDOM resource settings 743
Virtual domains in NAT/Route mode 743
Virtual clustering 743
Explicit proxy 744
Wireless 745
Encryption and authentication 745
Geographic location 745
Network planning 745
Lowering the power level to reduce RF interference 746
Wireless client load balancing 746
Local bridging 746
Advertising SSIDs 747
Using static IPs in a CAPWAP configuration 747
Logging and reporting 748
Log management 748
System memory and hard disks 749
Chapter 6 - FortiGate-6000 750
Fortigate-6000 750
FortiGate-6000 overview 750
Getting started with FortiGate-6000 754
Load balancing and flow rules 768
FortiGate-6000 IPsec VPN 776
FortiGate-6000 high availability (FGCP) 781
FortiGate-6000 v5.4.9 special features and limitations 791
FortiGate-6000 load balancing commands 795
Chapter 7 - FortiGate-7000 800
Fortigate-7000 800
What's new in for FortiGate-7000 v5.4.9 build 8110 800
What's new in for FortiGate-7000 v5.4.5 build 8047 800
FortiGate-7000 overview 804
Getting started with FortiGate-7000 822
Load balancing and flow rules 830

Operating a FortiGate-7000 836
IPsec VPN 842
High availability 848
FortiGate-7000 v5.4.9 special features and limitations 868
FortiGate-7000 v5.4.5 special features and limitations 873
FortiGate-7000 v5.4.3 special features and limitations 877
FortiGate-7000 Load balancing commands 882
Chapter 8 - FortiOS Carrier 887
Overview of FortiOS Carrier features 888
Overview 888
Registering FortiOS Carrier 888
MMS background 888
How FortiOS Carrier processes MMS messages 892
MMS protection profiles 902
Bypassing MMS protection profile filtering based on carrier endpoints 903
Applying MMS protection profiles to MMS traffic 903
GTP basic concepts 903
GPRS network common interfaces 911
Packet flow through the GPRS network 912
SCTP 913
Carrier web-based manager settings 919
MMS Security features 960
Why scan MMS messages for viruses and malware? 960
MMS virus scanning 961
Sender notifications and logging 968
MMS content-based Antispam protection 971
MMS DLP archiving 973
Message flood protection 975
Overview 975
Setting message flood thresholds 976
Notifying administrators of floods 977
Example — three flood threshold levels with different actions for each threshold 977
Notifying message flood senders and receivers 980
Viewing DLP archived messages 981
Order of operations: flood checking before duplicate checking 982
Bypassing message flood protection based on user's carrier endpoints 982
Configuring message flood detection 982
Sending administrator alert notifications 983
Duplicate message protection 986
Overview 986
Using message fingerprints to identify duplicate messages 987
Messages from any sender to any recipient 988

Setting duplicate message thresholds 988
Duplicate message actions 988
Notifying duplicate message senders and receivers 989
Viewing DLP archived messages 990
Order of operations: flood checking before duplicate checking 991
Bypassing duplicate message detection based on user's carrier endpoints 991
Configuring duplicate message detection 991
Sending administrator alert notifications 991
Configuring GTP on FortiOS Carrier 994
GTP support on the Carrier-enabled FortiGate unit 994
Configuring General Settings on the Carrier-enabled FortiGate unit 996
Configuring Encapsulated Filtering in FortiOS Carrier 997
Configuring the Protocol Anomaly feature in FortiOS Carrier 998
Configuring Anti-overbilling in FortiOS Carrier 999
Logging events on the Carrier-enabled FortiGate unit 999
GTP message type filtering 1002
Common message types on carrier networks 1002
Configuring message type filtering in FortiOS Carrier 1004
GTP identity filtering 1009
IMSI on carrier networks 1009
Other identity and location based information elements 1009
Configuring APN filtering in FortiOS Carrier 1012
Configuring IMSI filtering in FortiOS Carrier 1013
Configuring advanced filtering in FortiOS Carrier 1014
Troubleshooting 1016
FortiOS Carrier diagnose commands 1016
Applying IPS signatures to IP packets within GTP-U tunnels 1017
GTP packets are not moving along your network 1018
Chapter 9 - PCI DSS Compliance 1023
Compliance 1023
FortiOS 5.4 PCI DSS compliance new features 1023
Configuring FortiGate units for PCI DSS compliance 1025
Chapter 10 - Firewall 1040
FortiGate Firewall Components 1040
How does a FortiGate Protect Your Network? 1041
GUI & CLI - What You May Not Know 1043
What's new for the Firewall in 5.4 1046
New Features in 5.4.1 1049
New Features in 5.4.0 1050
Firewall concepts 1055
What is a Firewall? 1055
FortiGate Modes 1058

How Packets are handled by FortiOS 1059
Interfaces and Zones 1060
Access Control Lists 1061
IPv6 1061
NAT 1065
IP Pools 1077
Services and TCP ports 1080
Security policies 1107
Network defense 1135
Monitoring 1135
Blocking external probes 1135
Defending against DoS attacks 1139
Inside FortiOS: Denial of Service (DoS) Protection 1143
About DoS and DDoS attacks 1143
FortiOS DoS and DDoS protection 1144
FortiOS DDoS Prevention 1145
Configuration options 1146
DoS policies 1147
Hardware acceleration 1147
The FortiGuard Center 1147
Firewall Policies 1148
IPv4 Policy 1148
IPv6 Policy 1151
NAT64 Policy 1153
NAT46 Policy 1155
Central SNAT 1156
IPv4 Access Control List 1159
IPv6 Access Control List 1160
IPv4 DoS Policy 1161
IPv6 DoS Policy 1166
Firewall objects 1168
UUID Support 1169
Addresses 1170
Virtual IPs 1188
Configuring IP pools 1192
Services 1197
Service Groups 1210
Firewall schedules 1210
Chapter 11 - FortiView 1215
FortiView 1215
What's new in FortiOS 5.4 1216
Purpose 1225

Overview 1226
FortiView consoles 1237
Reference 1251
Troubleshooting FortiView 1262
Chapter 12 - Fortinet Communication Ports and Protocols 1263
Introduction 1263
FortiGate Open Ports 1264
FortiAnalyzer Open Ports 1267
FortiAP-S Open Ports 1269
FortiAuthenticator Open Ports 1271
FortiClient Open Ports 1274
FortiCloud Open Ports 1275
FortiDB Open Ports 1276
FortiGuard Open Ports 1277
FortiMail Open Ports 1280
FortiManager Open Ports 1283
FortiSandbox Open Ports 1286
Services and port numbers required for FortiSandbox 1287
3rd-Party Servers Open Ports 1288
Fortinet proprietary protocols 1290
FGCP - FortiGate Clustering Protocol 1291
FGSP - FortiGate Session Life Support Protocol 1298
FGFM - FortiGate to FortiManager protocol 1303
SLBC - Session-aware Load Balancing Cluster 1306
SF - Security Fabric 1314
FortiTelemetry/On-Net/FortiClient Endpoint Compliance 1316
FortiGuard 1319
FortiLink 1323
FortiOS WAN optimization 1329
FSSO - Fortinet Single Sign-On 1333
OFTP - Optimized Fabric Transfer Protocol 1337
FortiClient EMS - Enterprise Management Server 1338
Chapter 13 - FortiWiFi and FortiAP Configuration Guide 1340
What's new in FortiOS 5.4 1341
FortiOS 5.4.3 1341
FortiOS 5.4.1 1341
FortiOS 5.4.0 1344
Introduction to wireless networking 1354
Wireless concepts 1354
Security 1355
Authentication 1357
Wireless networking equipment 1357

Automatic Radio Resource Provisioning 1358
Configuring a WiFi LAN 1360
Overview of WiFi controller configuration 1360
Setting your geographic location 1362
Creating a FortiAP Profile 1363
Defining a wireless network interface (SSID) 1365
Defining SSID Groups 1374
Dynamic user VLAN assignment 1375
Configuring user authentication 1378
Configuring firewall policies for the SSID 1380
Configuring the built-in access point on a FortiWiFi unit 1382
Access point deployment 1383
Overview 1383
Network topology for managed APs 1383
Discovering and authorizing APs 1386
Advanced WiFi controller discovery 1392
Wireless client load balancing for high-density deployments 1393
FortiAP Groups 1395
LAN port options 1395
Preventing IP fragmentation of packets in CAPWAP tunnels 1398
LED options 1399
CAPWAP bandwidth formula 1399
Wireless Mesh 1402
Overview of Wireless Mesh 1402
Configuring a meshed WiFi network 1406
Configuring a point-to-point bridge 1409
Combining WiFi and wired networks with a software switch 1411
Combining WiFi and wired networks with a software switch 1411
FortiAP local bridging (Private Cloud-Managed AP) 1413
Using bridged FortiAPs to increase scalability 1415
Using Remote WLAN FortiAPs 1417
Configuring the FortiGate for remote FortiAPs 1417
Configuring the FortiAP units 1418
Preauthorizing FortiAP units 1419
Features for high-density deployments 1420
Broadcast packet suppression 1420
Multicast to unicast conversion 1420
Ignore weak or distant clients 1421
Turn off 802.11b protocol 1421
Disable low data rates 1421
Limit power 1422
Use frequency band load-balancing 1422

AP load balancing 1423
Application rate-limiting 1423
Protecting the WiFi Network 1425
Wireless IDS 1425
WiFi data channel encryption 1426
Protected Management Frames support 1427
Wireless network monitoring 1428
Monitoring wireless clients 1428
Monitoring rogue APs 1428
Suppressing rogue APs 1433
Monitoring wireless network health 1433
Configuring wireless network clients 1434
Windows XP client 1434
Windows 7 client 1439
Mac OS client 1443
Linux client 1445
Troubleshooting 1447
Wireless network examples 1450
Basic wireless network 1450
A more complex example 1455
Managing a FortiAP with FortiCloud 1465
FortiCloud-managed FortiAP WiFi 1465
FortiCloud-managed FortiAP WiFi without a key 1466
Using a FortiWiFi unit as a client 1468
Use of client mode 1468
Configuring client mode 1470
Support for location-based services 1471
Overview 1471
Configuring location tracking 1471
Viewing device location data on the FortiGate unit 1472
Troubleshooting 1473
Signal strength issues 1473
Throughput issues 1476
Connection issues 1478
General problems 1483
Packet sniffer 1485
Useful debugging commands 1489
Reference 1491
FortiAP web-based manager 1492
Wireless radio channels 1494
WiFi event types 1496
FortiAP CLI 1496

Chapter 14 - Hardening 1503
Install the FortiGate unit in a physically secure location 1503
Maintain the firmware 1503
Add new administrator accounts 1503
Change the admin account name and limit access to this account 1504
Only allow administrative access to the external interface when needed 1504
When enabling remote access, configure Trusted Hosts and Two-factor Authentication 1505
Change the default administrative port to a non-standard port 1505
Modify the device name 1506
Register with support services 1506
Disable sending Malware statistics to FortiGuard 1506
Maintain short login timeouts 1506
Enable automatic clock synchronization 1507
Enable Password Policy 1507
Modify administrator account Lockout Duration and Threshold values 1507
Disable auto installation via USB 1508
Configure auditing and logging 1508
Chapter 15 - Hardware Acceleration 1509
Whats New in Hardware Acceleration for FortiOS 5.4 1509
NP6 diagnose commands and get command changes (288738) 1509
NP6 session accounting enabled when traffic logging is enabled in a firewall policy (268426) 1509
Determining why a session is not offloaded (245447) 1510
IPsec pass-through traffic is now offloaded to NP6 processors (253221) 1510
Disabling offloading IPsec Diffie-Hellman key exchange (269555) 1510
FortiGate-3700DX TP2 processors support GTP offloading (294212) 1511
Preventing packet ordering problems with NP4 and NP6 FortiGates under heavy load (365497) 1511
Hardware acceleration overview 1512
Content processors (CP4, CP5, CP6, CP8, and CP9) 1512
Security processors (SPs) 1515
Network processors (NP1, NP2, NP3, NP4, NP4Lite, NP6 and NP6Lite) 1517
Enabling strict protocol header checking disables all hardware acceleration 1522
sFlow and NetFlow and hardware acceleration 1522
Checking that traffic is offloaded by NP processors 1522
Dedicated Management CPU 1524
Offloading flow-based content inspection with NTurbo and IPSA 1524
Preventing packet ordering problems with NP4, NP6 and NP6lite FortiGates under heavy load 1526
NP6 and NP6lite Acceleration 1527
NP6 session fast path requirements 1527
NP6Lite processors 1529

NP6 and NP6Lite processors and sFlow and NetFlow 1529
NP6 processors and traffic shaping 1529
NP Direct 1529
Viewing your FortiGate NP6 processor configuration 1530
Optimizing NP6 performance by distributing traffic to XAUI links 1531
Increasing NP6 offloading capacity using link aggregation groups (LAGs) 1532
NP6 processors and redundant interfaces 1533
Configuring Inter-VDOM link acceleration with NP6 processors 1534
Disabling offloading IPsec Diffie-Hellman key exchange 1537
Configuring individual NP6 processors 1537
Enabling per-session accounting for offloaded NP6 sessions 1541
Configure the number of IPsec engines NP6 processors use 1542
FortiGate NP6 architectures 1543
FortiGate-300D fast path architecture 1543
FortiGate-300E and 301E fast path architecture 1543
FortiGate-400D fast path architecture 1545
FortiGate-500D fast path architecture 1546
FortiGate-500E and 501E fast path architecture 1546
FortiGate-600D fast path architecture 1547
FortiGate-800D fast path architecture 1548
FortiGate-900D fast path architecture 1549
FortiGate-1000D fast path architecture 1551
FortiGate-1200D fast path architecture 1553
FortiGate-1500D fast path architecture 1556
FortiGate-1500DT fast path architecture 1557
FortiGate-2000E fast path architecture 1559
FortiGate-2500E fast path architecture 1561
FortiGate-3000D fast path architecture 1564
FortiGate-3100D fast path architecture 1565
FortiGate-3200D fast path architecture 1566
FortiGate-3700D fast path architecture 1569
FortiGate-3700DX fast path architecture 1573

FortiGate-3600C 1624
FortiGate-3950B and FortiGate-3951B 1625
FortiGate-3950B and FortiGate-3951B — load balance mode 1627
FortiGate-5001C 1628
FortiGate-5001B 1629
Setting switch-mode mapping on the ADM-XD4 1630
Hardware acceleration get and diagnose commands 1630
get hardware npu np6 1630
diagnose npu np6 1631
Using diagnose npu np6 npu-feature to verify enabled NP6 features 1632
Using the diagnose sys session/session6 list command 1633
diagnose npu np6 session-stats <np6-id> (number of NP6 IPv4 and IPv6 sessions) 1637
diagnose npu np6 ipsec-stats (NP6 IPsec statistics) 1638
diagnose sys mcast-session/session6 list (IPv4 and IPv6 multicast sessions) 1639

diagnose npu np6 sse-stats <np6-id> (number of NP6 sessions and dropped sessions) 1640
diagnose npu np6 dce <np6-id> (number of dropped NP6 packets) 1640
diagnose hardware deviceinfo nic <interfac-name> (number of packets dropped by an interface) 1641
dianose npu np6 synproxy-stats (NP6 SYN-proxied sessions and unacknowledged SYNs) 1642
Chapter 16 - High Availability 1643
FortiOS 5.4 HA new features 1643
Solving the High Availability problem 1647
FortiGate Cluster Protocol (FGCP) 1647
FortiGate Session Life Support Protocol (FGSP) 1648
VRRP 1649
Session-Aware Load Balancing Clustering (SLBC) 1650
Enhanced Load Balancing Clustering (ELBC) 1651
Content clustering 1651
An introduction to the FGCP 1653
About the FGCP 1653
Synchronizing the configuration (and settings that are not synchronized) 1656
Preparing the FortiGates before setting up a FGCP cluster 1657
Configuring FortiGates for FGCP HA operation 1659
Active-passive and active-active HA 1662
Identifying the cluster and cluster units 1664
Device failover, link failover, and session failover 1664
Primary unit selection 1665
HA override 1674
FortiGate HA compatibility with DHCP and PPPoE 1677
HA and distributed clustering 1678
Clusters of three or four FortiGates 1679
Disk storage configuration and HA 1683
FGCP high availability best practices 1684
FGCP HA terminology 1686
HA GUI options 1689
FGCP configuration examples and troubleshooting 1693
About the examples in this chapter 1693
How to set up FGCP clustering (recommended steps) 1693
Setting up two new FortiGates as an FGCP cluster 1700
Adding a new FortiGate to an operating cluster 1711
Active-active HA cluster in Transparent mode 1712
FortiGate-5000 active-active HA cluster with FortiClient licenses 1724
Converting a standalone FortiGate to a cluster 1735
Replacing a failed cluster unit 1739

FGCP HA with 802.3ad aggregated interfaces 1740
Example HA and redundant interfaces 1752
Troubleshooting HA clusters 1763
Virtual clusters 1768
Virtual clustering overview 1768
Configuring virtual clustering 1770
Example virtual clustering with two VDOMs and VDOM partitioning 1773
Example inter-VDOM links in a virtual clustering configuration 1785
Troubleshooting virtual clustering 1787
Full mesh HA 1789
Full mesh HA overview 1789
Example full mesh HA configuration 1791
Troubleshooting full mesh HA 1802
Operating clusters and virtual clusters 1803
Operating a cluster 1803
Operating a virtual cluster 1803
Managing individual cluster units using a reserved management interface 1804
Managing individual cluster units in a virtual cluster 1809
The primary unit acts as a router for subordinate unit management traffic 1809
Cluster communication with RADIUS and LDAP servers 1810
Clusters and FortiGuard services 1810
Clusters and logging 1811
Clusters and SNMP 1814
Adding FortiClient licenses to a cluster 1817
Cluster members list 1819
Virtual cluster members list 1820
Viewing HA statistics 1820
Changing the HA configuration of an operating cluster 1820
Changing the HA configuration of an operating virtual cluster 1821
Changing the subordinate unit host name and device priority 1821
Upgrading cluster firmware 1821
Downgrading cluster firmware 1823
Backing up and restoring the cluster configuration 1824
Monitoring cluster units for failover 1824
Viewing cluster status from the CLI 1825
Managing individual cluster units 1835
Disconnecting a cluster unit from a cluster 1836
Adding a disconnected FortiGate back to its cluster 1836
diagnose sys ha dump-by command 1837
HA and failover protection 1839
About active-passive failover 1839
About active-active failover 1840

Device failover 1840
HA heartbeat and communication between cluster units 1841
Cluster virtual MAC addresses 1848
Synchronizing the configuration 1855
Synchronizing kernel routing tables 1863
Configuring graceful restart for dynamic routing failover 1864
Link failover (port monitoring or interface monitoring) 1866
Monitoring VLAN interfaces 1872
Subsecond failover 1872
Remote link failover 1873
Failover and attached network equipment 1878
Monitoring cluster units for failover 1878
NAT/Route mode active-passive cluster packet flow 1878
Transparent mode active-passive cluster packet flow 1880
Failover performance 1883
Session failover (session-pickup) 1884
Enabling session-pickup for TCP, UDP and ICMP session failover 1885
If session pickup is disabled 1885
Improving session synchronization performance 1886
Session failover limitations for sessions passing through the cluster 1887
Session failover limitations for sessions terminated by the cluster 1890
Synchronizing IPsec VPN SAs 1891
WAN optimization and HA 1892
HA and load balancing 1893
Load balancing overview 1893
Selecting a load balancing schedule 1895
Load balancing TCP and UDP sessions 1896
Using NP4 or NP6 processors to offload load balancing 1896
Configuring weighted-round-robin weights 1896
Dynamically optimizing weighted load balancing according to how busy cluster units are 1897
Example weighted load balancing configuration 1899
NAT/Route mode active-active cluster packet flow 1901
Transparent mode active-active cluster packet flow 1904
HA with FortiGate-VM and third-party products 1908
FortiGate-VM for VMware HA configuration 1908
FortiGate VM for Hyper-V HA configuration 1908
Troubleshooting layer-2 switches 1909
Failover issues with layer-3 switches 1909
Failover and attached network equipment 1909
Ethertype conflicts with third-party switches 1910
LACP, 802.3ad aggregation and third-party switches 1910

VRRP 1911
Adding a VRRP virtual router to a FortiGate interface 1912
VRRP virtual MAC address 1912
VRRP Groups 1913
Using a Second Destination IP (VRDST) 1914
Configuring VRRP 1914
Example VRRP configuration: two FortiGates in a VRRP group 1914
Example VRRP configuration: VRRP load balancing two FortiGates and two VRRP groups 1916
Optional VRRP configuration settings 1917
FortiController-5000 support for VRRP HA 1917
FortiGate Session Life Support Protocol (FGSP) 1919
Configuring FGSP HA cluster-sync instances 1921
Synchronizing TCP and SCTP sessions 1922
Synchronizing the configuration 1922
FGSP and firmware upgrades 1922
IPsec tunnel synchronization 1923
Synchronizing UDP and ICMP (connectionless) sessions 1923
Synchronizing NAT sessions 1924
Synchronizing asymmetric sessions 1924
Synchronizing expectation sessions 1925
Security profile flow-based inspection and asymmetric traffic 1925
Notes and limitations 1926
Configuring session synchronization links 1926
Basic example configuration 1927
Verifying FGSP configuration and synchronization 1929
Chapter 17 - IPsec VPN 1931
Introduction 1931
What's new in FortiOS 5.4 1933
FortiOS 5.4.1 1933
FortiOS 5.4.0 1934
IPsec VPN concepts 1939
VPN tunnels 1939
VPN gateways 1941
Clients, servers, and peers 1943
Encryption 1943
Authentication 1944
Phase 1 and Phase 2 settings 1945
Security Association 1946
IKE and IPsec packet processing 1946
IPsec VPN overview 1950
Types of VPNs 1950

Planning your VPN 1951
General preparation steps 1953
How to use this guide to configure an IPsec VPN 1953
IPsec VPN in the web-based manager 1954
Phase 1 configuration 1954
Phase 2 configuration 1961
Concentrator 1965
IPsec Monitor 1966
Phase 1 parameters 1967
Overview 1967
Defining the tunnel ends 1967
Choosing Main mode or Aggressive mode 1968
Choosing the IKE version 1968
Authenticating the FortiGate unit 1969
Authenticating remote peers and clients 1972
Defining IKE negotiation parameters 1977
Using XAuth authentication 1982
Dynamic IPsec route control 1983
Phase 2 parameters 1985
Phase 2 settings 1985
Configuring the Phase 2 parameters 1987
Defining VPN security policies 1990
Defining policy addresses 1990
Defining security policies for policy-based and route-based VPNs 1991
Gateway-to-gateway 1996
Configuration overview 1996
Gateway-to-gateway configuration 1998
How to work with overlapping subnets 2003
Testing 2008
Hub-and-spoke configurations 2011
Configuration overview 2011
Configure the hub 2013
Configure the spokes 2018
Dynamic spokes configuration example 2021
Dynamic DNS configuration 2028
Dynamic DNS over VPN concepts 2028
DDNS topology 2030
Configuration overview 2031
FortiClient dialup-client configuration 2041
Configuration overview 2041
FortiGate dialup-client configurations 2050
Configuration overview 2050

Supporting IKE Mode Config clients 2058
IKE Mode Config overview 2058
Automatic configuration overview 2058
IKE Mode Config method 2058
Internet-browsing configuration 2063
Configuration overview 2063
Routing all remote traffic through the VPN tunnel 2065
Redundant VPN configurations 2067
Configuration overview 2067
Transparent mode VPNs 2072
Configuration overview 2072
IPv6 IPsec VPNs 2077
Configuration examples 2078
L2TP and IPsec (Microsoft VPN) 2089
Overview 2089
Assumptions 2090
Configuration overview 2090
GRE over IPsec (Cisco VPN) 2097
Configuration overview 2098
Configuring the Cisco router 2103
Protecting OSPF with IPsec 2104
Configuration overview 2104
Redundant OSPF routing over IPsec 2111
OSPF over dynamic IPsec 2115
BGP over dynamic IPsec 2118
IPsec Auto-Discovery VPN (ADVPN) 2122
Example ADVPN configuration 2123
Logging and monitoring 2128
Monitoring VPN connections 2128
VPN event logs 2129
Troubleshooting 2130
VPN troubleshooting tips 2136
General troubleshooting tips 2136
Troubleshooting L2TP and IPsec 2138
Troubleshooting GRE over IPsec 2140
Chapter 18 - IPv6 2143
Possible addresses: 2143
IPv6 packet structure 2144
Benefits of IPv6 2144
What's new for IPv6 in FortiOS 5.4 2144
New features in 5.4.0 2144
IPv6 Features 2147

IPv6 policies 2147
IPv6 Network Address Translation 2155
ICMPv6 2160
IPv6 in dynamic routing 2164
Dual stack routing 2165
IPv6 tunnelling 2165
SIP over IPv6 2166
New Fortinet FortiGate IPv6 MIB fields 2167
IPv6 Per-IP traffic shaper 2168
DHCPv6 2169
IPv6 forwarding 2170
Obtaining IPv6 addresses from an IPv6 DHCP server 2170
IPv6 Configuration 2171
IPv6 address groups 2171
IPv6 address ranges 2172
IPv6 firewall addresses 2172
ICMPv6 2174
IPv6 IPsec VPN 2175
TCP MSS values 2188
BGP and IPv6 2188
RIPng — RIP and IPv6 2189
IPv6 RSSO support 2195
IPv6 IPS 2195
Blocking IPv6 packets by extension headers 2195
IPv6 Denial of Service policies 2196
Configure hosts in an SNMP v1/2c community to send queries or receive traps 2196
IPv6 PIM sparse mode multicast routing 2196
Chapter 19 - Logging and Reporting 2197
Logging and reporting overview 2198
What is logging? 2198
FortiOS features available for logging 2199
Log messages 2204
Log files and types 2210
Log database and datasets 2211
Log devices 2213
Reports 2217
Best Practices: Log management 2218
Logging and reporting for small networks 2220
Modifying default log device settings 2220
Configuring the backup solution 2222
Logging and reporting for large networks 2224
Modifying default log device settings 2224

Configuring the backup solution 2226
Advanced logging 2229
Configuring logging to multiple Syslog servers 2229
Using Automatic Discovery to connect to a FortiAnalyzer unit 2230
Activating a FortiCloud account for logging purposes 2230
Viewing log storage space 2231
Customizing and filtering log messages 2231
Viewing logs from the CLI 2232
Configuring NAC quarantine logging 2232
Logging local-in policies 2233
Tracking specific search phrases in reports 2235
Troubleshooting and logging 2237
Using log messages to help in troubleshooting issues 2237
Connection issues between FortiGate unit and logging devices 2238
Log database issues 2238
Logging daemon (Miglogd) 2240
Chapter 20 - Managing Devices 2241
What's New in FortiOS 5.4 2242
Managing “bring your own device” 2245
Device monitoring 2245
Device Groups 2246
Controlling access with a MAC Address Access Control List 2246
Security policies for devices 2247
Chapter 21 - Managing a FortiSwitch with a FortiGate 2251
Introduction 2251
Supported Models 2251
What's New 2252
Before You Begin 2253
How this Guide is Organized 2253
Connecting FortiLink Ports 2254
Summary of the Steps 2254
Enable the Switch Controller on FortiGate 2254
Connect the FortiSwitch and FortiGate 2254
Choosing the FortiGate Ports 2256
FortiLink Configuration Using FortiGate GUI 2257
Summary of the Steps 2257
Configure FortiLink as a Single Link 2257
Configure FortiLink as a Logical Interface 2257
FortiLink Split-Interface 2258
Authorizing the FortiSwitch 2258
Managed FortiSwitch Display 2258
Edit Managed FortiSwitch 2259

Network Interface Display 2260
FortiLink Configuration Using FortiGate CLI 2261
Summary of the Steps 2261
Configure FortiLink as a Single Link 2261
Configure FortiLink as a Logical Interface 2262
Configuring FortiLink for FortiGate HA 2264
Example Topology 2264
Adding a Second FortiGate to Existing Single FortiGate 2265
Adding the First Switch to Existing HA FortiGates (single FortiLinks) 2265
Adding the First Switch to Existing FGT HA setup (Logical Fortilink Interface) 2266
(Optional) Test the HA Capability 2266
Network Topologies for Managed FortiSwitch 2267
Supported Topologies 2267
Stacking Configuration 2271
Optional Setup Tasks 2272
Configuring FortiSwitch Management Port 2272
Converting to FortiSwitch Standalone Mode 2272
VLAN Configuration 2274
FortiSwitch VLANs Display 2274
Creating VLANs 2274
FortiSwitch Port Features 2277
FortiSwitch Ports Display 2277
Configuring Ports Using the Web Manager 2278
Configuring Ports Using the FortiGate CLI 2278
Additional Capabilities 2280
FortiSwitch LOG export 2280
FortiSwitch Per-Port Device Visibility 2280
FortiGate CLI support for FortiSwitch features (on non-FortiLink ports) 2280
Execute Custom FortiSwitch Commands 2281
Troubleshooting 2283
Troubleshooting FortiLink Issues 2283
Chapter 22 - Networking 2284
What's new for Networking in FortiOS 5.4 2285
New Features in 5.4.1 2285
New Features in 5.4.0 2291
Interfaces 2298
Administrative access 2298
Aggregate Interfaces 2299
DHCP addressing mode on an interface 2300
DHCP servers and relays 2301
Interface MTU packet size 2306
Interface settings 2307

Loopback interfaces 2312
One-armed sniffer 2313
Physical 2314
PPPoE addressing mode on an interface 2315
Probing interfaces 2317
Redundant interfaces 2317
Dual Internet connections (redundant Internet connections) 2318
Secondary IP addresses to an interface 2320
Software switch 2321
Soft switch example 2322
Virtual Switch 2322
Zones 2323
Virtual domains 2324
Wireless 2325
VLANs 2325
DNS 2338
DNS Servers 2339
Packet Capture 2341
Advanced Static Routing 2343
Routing concepts 2343
Static routing tips 2357
Policy routing 2358
Transparent mode static routing 2361
Static routing example 2362
Dynamic Routing Overview 2371
What is dynamic routing? 2371
Comparison of dynamic routing protocols 2374
Choosing a routing protocol 2379
Dynamic routing terminology 2380
IPv6 in dynamic routing 2385
Routing Information Protocol (RIP) 2387
RIP background and concepts 2387
Troubleshooting RIP 2399
Simple RIP example 2403
RIPng — RIP and IPv6 2418
Open Shortest Path First (OSPF) 2424
OSPF Background and concepts 2424
Troubleshooting OSPF 2436
Basic OSPF example 2438
Advanced inter-area OSPF example 2450
Controlling redundant links by cost 2461
Border Gateway Protocol (BGP) 2465

BGP background and concepts 2465
Troubleshooting BGP 2477
Dual-homed BGP example 2482
Redistributing and blocking routes in BGP 2495
Intermediate System to Intermediate System Protocol(IS-IS) 2502
IS-IS background and concepts 2502
How IS-IS works 2502
Troubleshooting IS-IS 2508
Simple IS-IS example 2511
Network layout and assumptions 2512
Expectations 2513
CLI configuration 2513
Verification 2515
Troubleshooting 2518
Multicast forwarding 2519
Sparse mode 2519
Dense mode 2520
PIM Support 2521
Multicast forwarding and FortiGate units 2522
Configuring FortiGate multicast forwarding 2523
Multicast routing examples 2526
Chapter 23 - Parallel Path Processing - Life of a Packet 2551
Life of a Packet 2551
Parallel Path Processing 2551
Packet flow ingress and egress: FortiGates without network processor offloading 2553
Packet flow: FortiGates with NP6 processors first packet of a new session 2558
Packet flow: FortiGates with NP6 processors - packets in an offloaded session 2560
Packet flow: FortiGates with NP6 processors - packets in an NTurbo session 2560
UTM/NGFW packet flow: flow-based inspection 2562
UTM/NGFW packet flow: proxy-based inspection 2564
Comparison of inspection types 2565
Chapter 24 - Sandbox Inspection 2568
Sandbox Inspection 2568
An Overview of Sandbox Inspection 2569
Using FortiSandbox with a FortiGate 2571
Sandbox Integration 2573
Sandbox Inspection FAQ 2577
Chapter 25 - Fortinet Security Fabric 2578
FortiGate Security Fabric 2578
Overview 2579
Example Network 2584
Core Devices 2585

Extended Devices 2592
Chapter 26 - Security Profiles 2598
What's New in FortiOS 5.4 2599
FortiOS 5.4.1 2599
What's New in FortiOS 5.4.0 2604
Cloud Access Security Inspection (CASI) 2608
External Security Devices 2611
Other new Security Profile features 2615
Inside FortiOS: AntiVirus 2625
Advanced Protection against Malware and APTs 2625
Features 2626
Recipes 2628

SSL server table for SSL offloading 2797
Custom Application & IPS Signatures 2798
Creating a custom IPS signature 2798
Custom signature syntax 2798
Custom signature keywords 2799
Creating a custom signature to block access to example.com 2811
Creating a custom signature to block the SMTP “vrfy” command 2813
Creating a custom signature to block files according to the file's hash value 2814
Other Security Profiles considerations 2816
Security Profiles and Virtual domains (VDOMs) 2816
Conserve mode 2816
Using wildcards and Perl regular expressions 2818
Adding External Security Devices 2820
External Security Devices 2820
CPU allocation and tuning commands to survive reboot 2822
Chapter 27 - Server Load Balancing 2824
Inside FortiOS: Server Load Balancing 2824
Server Load Balancing combined with NGFW and UTM protection 2824
SSL/TLS offloading 2825
SSL/TLS content inspection 2826
Health Check 2826

Server Monitoring and Management 2826
HTTP Multiplexing 2826
New load balancing features in FortiOS 5.4 2826
FortiOS 5.4.1 2827
FortiOS 5.4.0 2829
Basic load balancing configuration example 2831
Configuring load balancing 2836
Load balancing and other FortiOS features 2839
Configuring load balancing from the GUI 2839
Configuring load balancing from the CLI 2841
Load balancing methods 2842
Session persistence 2843
Real servers 2843
Health check monitoring 2845
Load balancing limitations 2847
Monitoring load balancing 2847
Load balancing diagnose commands 2848
HTTP and HTTPS load balancing, multiplexing, and persistence 2850
HTTP and HTTPS multiplexing 2850
HTTP and HTTPS persistence 2851
HTTP host-based load balancing 2853
SSL/TLS load balancing 2854
SSL/TLS offloading 2855
Separate virtual-server client and server TLS version and cipher configuration 2857
Setting the SSL/TLS versions to use for server and client connections 2857
Setting the SSL/TLS cipher choices for server and client connections 2858
Protection from TLS protocol downgrade attacks 2859
Setting 3072- and 4096-bit Diffie-Hellman values 2859
Additional SSL load balancing and SSL offloading options 2859
SSL offloading support for Internet Explorer 6 2860
Selecting the cipher suites available for SSL load balancing 2861
Disabling SSL/TLS re-negotiation 2861
IP, TCP, and UDP load balancing 2865
Example HTTP load balancing to three real web servers 2865
Web-based manager configuration 2866
CLI configuration 2869
Example Basic IP load balancing configuration 2871
Example Adding a server load balance port forwarding virtual IP 2871
Example Weighted load balancing configuration 2873
GUI configuration 2873
CLI configuration 2876
Example HTTP and HTTPS persistence configuration 2876

CLI configuration: adding persistence for a specific domain 2880
Chapter 28 - SSL VPN 2882
What's new in FortiOS 5.4 2883
FortiOS 5.4.1 2883
FortiOS 5.4.0 2883
SSL VPN Overview 2886
SSL VPN modes of operation 2887
Port forwarding mode 2889
Traveling and security 2890
SSL VPN and IPv6 2891
Basic configuration 2892
User accounts and groups 2892
Configuring SSL VPN web portals 2896
Configuring security policies 2902
Configuring encryption key algorithms 2908
Additional configuration options 2909
The SSL VPN client 2918
FortiClient 2918
Tunnel mode client configuration 2918
The SSL VPN web portal 2920
Connecting to the FortiGate unit 2920
Web portal overview 2920
Portal configuration 2921
Using the Bookmarks widget 2925
Using the Quick Connection Tool 2927
Using the SSL VPN virtual desktop 2931
Using FortiClient 2931
Setup examples 2933
Secure Internet browsing 2933
Split Tunnel 2935
Multiple user groups with different access permissions 2938
Troubleshooting 2944
Chapter 29 - System Administration 2947
What's New in FortiOS 5.4 2948
FortiOS 5.4.2 2948
FortiOS 5.4.1 2950
FortiOS 5.4.0 2951
Administrators 2960
Central management 2968
Adding a FortiGate to FortiManager 2968
Configuration updates through FortiManager 2970
FortiGuard 2970

Firmware updates 2971
Administrative domains 2972
Backup and restore configurations 2972
Monitoring 2972
Dashboard 2973
sFlow 2974
Monitor menus 2975
Logging 2975
Alert email 2976
SNMP 2977
SNMP get command syntax 2985
Replacement messages 2985
Administration for schools 2991
PPTP and L2TP 2994
How PPTP VPNs work 2994
FortiGate unit as a PPTP server 2996
Configuring the FortiGate unit for PPTP VPN 2999
Configuring the FortiGate unit for PPTP passthrough 2999
Testing PPTP VPN connections 3001
Logging VPN events 3001
Configuring L2TP VPNs 3002
L2TP configuration overview 3004
Session helpers 3007
Viewing the session helper configuration 3008
Changing the session helper configuration 3009
DCE-RPC session helper (dcerpc) 3011
DNS session helpers (dns-tcp and dns-udp) 3012
File transfer protocol (FTP) session helper (ftp) 3012
H.245 session helpers (h245I and h245O) 3012
H.323 and RAS session helpers (h323 and ras) 3012
Media Gateway Controller Protocol (MGCP) session helper (mgcp) 3013
ONC-RPC portmapper session helper (pmap) 3013
PPTP session helper for PPTP traffic (pptp) 3014
Remote shell session helper (rsh) 3015
Real-Time Streaming Protocol (RTSP) session helper (rtsp) 3015
Session Initiation Protocol (SIP) session helper (sip) 3016
Trivial File Transfer Protocol (TFTP) session helper (tftp) 3016
Oracle TNS listener session helper (tns) 3016
Advanced concepts 3017
Single firewall vs. multiple virtual domains 3017
Modem 3019
Assigning IP address by MAC address 3022

IP addresses for self-originated traffic 3023
Disk 3023
CLI Scripts 3024
Rejecting PING requests 3025
Opening TCP 113 3026
Obfuscate HTTP responses 3026
Chapter 30 - Traffic Shaping 3027
What's new in FortiOS 5.4 3027
FortiOS 5.4.1 3027
FortiOS 5.4.0 3028
New button added to "Clone" Shapers 3029
The purpose of traffic shaping 3030
Quality of Service 3030
Traffic policing 3031
Bandwidth guarantee, limit, and priority interactions 3032
FortiGate traffic 3032
Through traffic 3033
Important considerations 3037
Traffic shaping methods 3039
Traffic shaping options 3039
Shared policy shaping 3040
Per-IP shaping 3045
Per-IP traffic shaping configuration settings 3045
Adding a Per-IP traffic shaper to a traffic shaping policy 3046
Application control shaping 3048
Reverse direction traffic shaping 3050
Enabling traffic shaping in the security policy 3051
Type of Service priority 3052
Differentiated Services 3053
DSCP examples 3054
ToS and DSCP traffic mapping 3058
Traffic Shaper Monitor 3059
Examples 3061
QoS using priority from security policies 3061
QoS using priority from ToS or differentiated services 3065
Example setup for VoIP 3066
Troubleshooting traffic shaping 3072
Interface diagnosis 3072
Shaper diagnose commands 3072
Packet lost with the debug flow 3074
Session list details with dual traffic shaper 3074
Additional Information 3074

Chapter 31 - Transparent Mode **3076**
Introduction to Transparent Mode 3076
What is Transparent Mode? 3076
Transparent Mode Features 3076
Transparent Mode Installation 3078
Installing a FortiGate in Transparent mode 3078
Using a Virtual Wire Pair to Simplify Transparent Mode 3080
Management IP configuration 3080
Networking in Transparent Mode 3082
Packet Forwarding 3082
Network Address Translation (NAT) 3087
VLANs and Forwarding Domains 3088
Inter-VDOM links between NAT/Route and Transparent VDOMs 3091
Replay Traffic Scenario 3091
Packet Forwarding using Cisco Protocols 3092
Configuration Example 3094
Firewalls and Security in Transparent Mode 3095
Firewall Policy Look Up 3095
Firewall Session List 3095
Security Scanning 3096
Integrated Switch Fabric Access Control List Policies 3096
IPsec VPN in Transparent Mode 3097
Using IPsec VPNs in Transparent Mode 3097
Example 1: Remote Sites with Different Subnets 3098
Example 2: Remote Sites on the Same Subnet 3104
Using FortiManager and FortiAnalyzer 3110
High Availability in Transparent Mode 3110
Virtual Clustering 3111
MAC Address Assignment 3112
Best Practices 3112
Chapter 32 - Troubleshooting **3113**
Troubleshooting methodologies 3114
Establish a baseline 3114
Define the problem 3115
Gathering Facts 3116
Create a troubleshooting plan 3116
Obtain any required additional equipment 3117
Ensure you have administrator level access to required equipment 3117
Contact Fortinet customer support for assistance 3117
Troubleshooting tools 3118
FortiOS diagnostics 3118
FortiOS ports 3142

FortiAnalyzer/FortiManager ports 3143
FortiGuard troubleshooting 3143
Common questions 3147
How to check hardware connections 3148
How to check FortiOS network settings 3149
How to check CPU and memory resources 3150
How to check modem status 3155
How to run ping and traceroute 3155
How to check the logs 3159
How to verify the contents of the routing table (in NAT mode) 3160
How to verify the correct route is being used 3161
How to verify the correct firewall policy is being used 3162
How to check the bridging information in Transparent mode 3162
How to check number of sessions used by UTM proxy 3164
How to examine the firewall session list 3167
How to check wireless information 3168
How to verify FortiGuard connectivity 3169
How to perform a sniffer trace (CLI and Packet Capture) 3169
How to debug the packet flow 3172
Troubleshooting resources 3173
Technical Documentation 3173
Fortinet Video Library 3173
Release Notes 3173
Knowledge Base 3173
Fortinet Technical Discussion Forums 3173
Fortinet Training Services Online Campus 3173
Fortinet Customer Support 3174
Technical Support Organization Overview 3175
Fortinet Global Customer Services Organization 3175
Creating an account 3176
Registering a device 3177
Reporting problems 3178
Assisting technical support 3180
Support priority levels 3180
Return material authorization process 3181
Chapter 33 - Virtual Domains 3182
What's new in FortiOS 5.4 3182
Stackable VDOM licenses 3182
Support execution of global CLI commands from within VDOMs 3183
GUI features can now be enabled and disabled per VDOM 3183
Improvements and changes to per-VDOM certificates 3183
Adding option for VDOM logs through management VDOM 3185

Virtual Domains Overview 3186
Benefits of Virtual Domains 3186
Enabling and accessing Virtual Domains 3188
Configuring Virtual Domains 3194
Virtual Domains in NAT/Route mode 3200
Using a VDOM in NAT/Route mode 3200
Example configuration: VDOM in NAT/Route mode 3208
Virtual Domains in Transparent mode 3219
Transparent Mode Overview 3219
Operation mode differences in VDOMs 3220
Using a VDOM in Transparent mode 3221
Example configuration: VDOM in Transparent mode 3222
Inter-VDOM routing 3236
Benefits of inter-VDOM routing 3236
Inter-VDOM configurations 3237
Configuring VDOM links 3240
Dynamic routing over inter-VDOM links 3243
HA virtual clusters and VDOM links 3244
Example configuration: Inter-VDOM routing 3245
Troubleshooting Virtual Domains 3268
VDOM admin having problems gaining access 3268
FortiGate unit running very slowly 3268
General VDOM tips and troubleshooting 3269
Chapter 34 - VM Installation 3273
What's new in VM in 5.4 3273
New Features in 5.4.1 3273
New Features in 5.4.0 3275
FortiGate VM Overview 3277
FortiGate VM models and licensing 3277
Registering FortiGate VM with Customer Service & Support 3278
Downloading the FortiGate VM deployment package 3278
Deployment package contents 3280
Deploying the FortiGate VM appliance 3281
Deployment example – VMware 3282
Open the FortiGate VM OVF file with the vSphere client 3282
Configure FortiGate VM hardware settings 3287
Transparent mode VMware configuration 3288
High Availability VMware configuration 3288
Power on your FortiGate VM 3289
Deployment example – MS Hyper-V 3290
Create the FortiGate VM virtual machine 3290
Configure FortiGate VM hardware settings 3297

High Availability Hyper-V configuration 3308
Start the FortiGate VM 3309
Deployment example – KVM 3310
Create the FortiGate VM virtual machine 3310
Configure FortiGate VM hardware settings 3312
Start the FortiGate VM 3313
Deployment example – OpenXen 3314
Create the FortiGate VM virtual machine (VMM) 3314
Deployment example – Citrix XenServer 3320
Create the FortiGate VM virtual machine (XenCenter) 3320
Configure virtual hardware 3323
FortiGate VM Initial Configuration 3327
Set FortiGate VM port1 IP address 3327
Connect to the FortiGate VM Web-based Manager 3330
Upload the FortiGate VM license file 3330
Validate the FortiGate VM license with FortiManager 3332
Configure your FortiGate VM 3333
Chapter 35 - VoIP Solutions: SIP 3335
Inside FortiOS: Voice over IP (VoIP) Protection 3336
Advanced Voice over IP Protection 3336
Carrier Grade protection 3338
NAT/NAPT 3338
SIP ALG activation 3340
SIP over IPv6 3341
Platform support and hardware acceleration 3341
Common SIP VoIP configurations 3342
Peer to peer configuration 3342
SIP proxy server configuration 3342
SIP redirect server configuration 3343
SIP registrar configuration 3344
SIP with a FortiGate 3345
SIP messages and media protocols 3348
Hardware accelerated RTP processing 3350
SIP request messages 3350
SIP response messages 3351
SIP message start line 3353
SIP headers 3353
The SIP message body and SDP session profiles 3355
Example SIP messages 3358
The SIP session helper 3359
SIP session helper configuration overview 3359
Disabling and enabling the SIP session helper 3360

Changing the port numbers that the SIP session helper listens on 3361
Configuration example: SIP session helper in Transparent Mode 3361
SIP session helper diagnose commands 3364
The SIP ALG 3364
Enabling VoIP support from the GUI 3367
SIP ALG configuration overview 3367
VoIP profiles 3367
Changing the port numbers that the SIP ALG listens on 3369
Disabling the SIP ALG in a VoIP profile 3369
SIP ALG diagnose commands 3369
Conflicts between the SIP ALG and the session helper 3370
Stateful SIP tracking, call termination, and session inactivity timeout 3370
Adding a media stream timeout for SIP calls 3371
Adding an idle dialog setting for SIP calls 3372
Changing how long to wait for call setup to complete 3372
SIP and RTP/RTCP 3372
How the SIP ALG creates RTP pinholes 3373
Configuration example: SIP in Transparent Mode 3374
General configuration steps 3375
Configuration steps - GUI 3375
Configuration steps - CLI 3377
RTP enable/disable (RTP bypass) 3377
Opening and closing SIP register, contact, via and record-route pinholes 3378
Accepting SIP register responses 3379
How the SIP ALG performs NAT 3379
SIP ALG source address translation 3380
SIP ALG destination address translation 3380
SIP Call Re-invite messages 3380
How the SIP ALG translates IP addresses in SIP headers 3381
How the SIP ALG translates IP addresses in the SIP body 3383
SIP NAT scenario: source address translation (source NAT) 3384
SIP NAT scenario: destination address translation (destination NAT) 3387
SIP NAT configuration example: source address translation (source NAT) 3389
SIP NAT configuration example: destination address translation (destination NAT) 3391
SIP and RTP source NAT 3395
SIP and RTP destination NAT 3395
Source NAT with an IP pool 3397
Different source and destination NAT for SIP and RTP 3397
NAT with IP address conservation 3398
Controlling how the SIP ALG NATs SIP contact header line addresses 3399
Controlling NAT for addresses in SDP lines 3400
Translating SIP session destination ports 3400

Translating SIP sessions to multiple destination ports 3402
Adding the original IP address and port to the SIP message header after NAT 3403
Enhancing SIP pinhole security 3403
Hosted NAT traversal 3406
Configuration example: Hosted NAT traversal for calls between SIP Phone A and SIP Phone B 3407
Hosted NAT traversal for calls between SIP Phone A and SIP Phone C 3411
Restricting the RTP source IP 3411
SIP over IPv6 3411
Deep SIP message inspection 3412
Actions taken when a malformed message line is found 3413
Logging and statistics 3414
Deep SIP message inspection best practices 3414
Configuring deep SIP message inspection 3414
Blocking SIP request messages 3417
SIP rate limiting 3419
Limiting the number of SIP dialogs accepted by a security policy 3421
SIP logging 3421
Inspecting SIP over SSL/TLS (secure SIP) 3421
Adding the SIP server and client certificates 3424
Adding SIP over SSL/TLS support to a VoIP profile 3424
SIP and HA–session failover and geographic redundancy 3425
SIP geographic redundancy 3426
Supporting geographic redundancy when blocking OPTIONS messages 3426
Support for RFC 2543-compliant branch parameters 3427
SIP and IPS 3427
SIP debugging 3428
SIP debug log format 3428
SIP-proxy filter per VDOM 3429
SIP-proxy filter command 3429
SIP debug setting 3429
Display SIP rate-limit data 3430
Chapter 36 - WAN Optimization, Web Cache, Explicit Proxy, and WCCP 3431
Toggling Disk Usage for logging or wan-opt 3431
Distributing WAN optimization, explicit proxy, and web caching to multiple CPU Cores 3432
How this chapter is organized 3433
Inside FortiOS: WAN Optimization 3433
Centralize without compromising your WAN performance 3433
FortiOS WAN Optimization 3434
Protocol optimization 3434
Web caching 3434
Byte caching 3435

Server Monitoring and Management 3435
SSL acceleration 3435
VPN replacement 3436
Road warriors and home workers 3436
What's new in FortiOS 5.4 3437
New explicit proxy features 3439
FortiOS 5.4.1 3439
FortiOS 5.4.0 3440
Example network topologies 3443
Basic WAN optimization topology 3443
Out-of-path WAN Optimization topology 3444
Topology for multiple networks 3445
WAN optimization with web caching 3445
WAN optimization and web caching with FortiClient peers 3446
Explicit Web proxy topologies 3446
Explicit FTP proxy topologies 3447
Web caching topologies 3447
WCCP topologies 3448
Configuring WAN optimization 3450
Client/server architecture 3450
WAN optimization peers 3451
Manual (peer-to-peer) and active-passive WAN optimization 3451
WAN optimization profiles 3454
Protocol optimization 3457
Protocol optimization and MAPI 3457
Byte caching 3457
WAN optimization transparent mode 3458
FortiClient WAN optimization 3459
Operating modes and VDOMs 3459
WAN optimization tunnels 3459
WAN optimization and user and device identity policies, load balancing and traffic shaping 3461
WAN optimization and HA 3461
WAN optimization, web caching and memory usage 3462
Monitoring WAN optimization performance 3462
WAN optimization configuration summary 3464
Best practices 3466
Peers and authentication groups 3468
Basic WAN optimization peer requirements 3468
How FortiGate units process tunnel requests for peer authentication 3468
Configuring peers 3469
Configuring authentication groups 3470

Secure tunneling 3472
Monitoring WAN optimization peer performance 3473
Configuration examples 3474
Example Basic manual (peer-to-peer) WAN optimization configuration 3474
Example Active-passive WAN optimization 3480
Example Adding secure tunneling to an active-passive WAN optimization configuration 3488
Web caching and SSL offloading 3495
Turning on web caching for HTTP and HTTPS traffic 3495
Turning on web caching for HTTPS traffic 3496
Changing the ports on which to look for HTTP and HTTPS traffic to cache 3498
Web caching and HA 3499
Web caching and memory usage 3499
Changing web cache settings 3499
Forwarding URLs to forwarding servers and exempting web sites from web caching 3502
Monitoring Web caching performance 3503
Example Web caching of HTTP and HTTPS Internet content for users on an internal network 3503
Example reverse proxy web caching and SSL offloading for an Internet web server using a static one-to-one virtual IP 3507
Network topology and assumptions 3507
FortiClient WAN optimization 3512
FortiClient WAN optimization over IPsec VPN configuration example 3512
The FortiGate explicit web proxy 3515
General explicit web proxy configuration steps 3516
Explicit proxy firewall address types 3520
Proxy auto-config (PAC) configuration 3520
Unknown HTTP version 3521
Authentication realm 3521
Implementing Botnet features 3521
Other explicit web proxy options 3522
Configuring an external IP address for the IPv4 explicit web proxy 3522
Configuring an external IP address for the IPv6 explicit web proxy 3522
Restricting the IP address of the IPv4 explicit web proxy 3522
Restricting the outgoing source IP address of the IPv4 explicit web proxy 3523
Restricting the IP address of the explicit IPv6 web proxy 3523
Restricting the outgoing source IP address of the IPv6 explicit web proxy 3523
Proxy chaining (web proxy forwarding servers) 3523
Adding disclaimer messages to explicit proxy policies 3527
Explicit web proxy authentication 3527
Security profiles, threat weight, device identification, and the explicit web proxy 3530
Web Proxy firewall services and service groups 3530
Explicit web proxy firewall address URL patterns 3531

Changing HTTP headers 3532
Preventing the explicit web proxy from changing source addresses 3532
Explicit web proxy sessions and user limits 3538
Kerberos authentication for explicit proxy users 3539
The FortiGate explicit FTP proxy 3545
How to use the explicit FTP proxy to connect to an FTP server 3546
General explicit FTP proxy configuration steps 3548
Restricting the IP address of the explicit FTP proxy 3550
Restricting the outgoing source IP address of the explicit FTP proxy 3551
Security profiles, threat weight, device identification, and the explicit FTP proxy 3551
Example users on an internal network connecting to FTP servers on the Internet through the explicit FTP with RADIUS authentication and virus scanning 3551
Explicit FTP proxy sessions and user limits 3556
FortiGate WCCP 3557
WCCP service groups, service numbers, service IDs and well known services 3557
WCCP configuration overview 3561
Example caching HTTP sessions on port 80 using WCCP 3561
Example caching HTTP sessions on port 80 and HTTPS sessions on port 443 using WCCP 3564
WCCP packet flow 3566
Configuring the forward and return methods and adding authentication 3566
WCCP Messages 3567
Troubleshooting WCCP 3567
Diagnose commands 3569
get test {wad | wccpd} <test_level> 3569
diagnose wad 3570
diagnose wacs 3573
diagnose wadbd 3574
diagnose debug application {wad | wccpd} [<debug_level>] 3574
diagnose test application wad 2200 3574

Chapter 1 - What's New for FortiOS 5.4

This FortiOS Handbook chapter contains the following sections.

What's New in FortiOS 5.4.6 provides a brief description of features that were added to FortiOS 5.4.6.

What's New in FortiOS 5.4.4 provides a brief description of features that were added to FortiOS 5.4.4.

What's New in FortiOS 5.4.3 provides a brief description of features that were added to FortiOS 5.4.3.

What's New in FortiOS 5.4.2 provides a brief description of features that were added to FortiOS 5.4.2.

There is no What's New in FortiOS 5.4.5 because there were no new features added in that version.

The following sections highlight some of the higher profile new FortiOS 5.4 features:

- Cooperative Security Fabric (CSF)
- Policy Learning Mode
- FortiView
- Cloud Access Security Inspection (CASI)
- Managed FortiSwitch
- Changing the FortiGate's inspection mode to flow or proxy
- GUI Refresh
- DNS Filter
- FortiSandbox Integration
- Traffic Shaping Policies
- WAN link load balancing
- Virtual Wire Pair

All of the other new features in FortiOS 5.4 are organized alphabetically by subject:

- Authentication
- PCI DSS compliance
- Device identification
- Diagnose command changes
- Explicit web proxy
- Firewall
- FortiGate VM
- Hardware acceleration
- High Availability
- IPsec VPN
- IPv6
- Load balancing
- Logging and Reporting

- Maximum values changes
- Networking
- RFCs supported by FortiOS 5.4
- Security Profiles
- Session-aware Load Balancing (SLBC)
- SSL VPN
- System
- VDOMs
- WAN Optimization
- WiFi

What's New in FortiOS 5.4.6

Most development work in FortiOS 5.4.6 involved resolving issues. However, the following new features were added as well.

User group authentication timeout range increased to 30 days (378085)

The user authentication timeout for users in a user group has been extended to 30 days.

```
config user group
   edit <group-name>
      set authtimeout 43200
   end
```

Where `authtimeout` is the length of the timeout in minutes. An `authtimeout` of 43200 minutes is equivalent to 30 days. Set `authtimeout` to 0 to use the default authentication timeout.

FortiOS-VM support 10 interfaces (397860)

New installations of FortiOS-VM for FortiOS 5.4.6 now include 10 interfaces.

Improved support for RFCs 5746 and 7627 (422133)

FortiOS includes improved support of RFC 5746 : TLS Renegotiation Indication Extension and RFC 7627: TLS Session Hash and Extended Master Secret Extension.

Stripping clear text padding and IPsec session ESP padding (416950)

In some situations, when clear text or ESP packets in IPsec sessions may have large amounts of layer 2 padding, the NP6 IPsec engine may not be able to process them and the session may be blocked.

If you notice dropped IPsec sessions, you could try using the following CLI options to cause the NP6 processor to strip clear text padding and ESP padding before sending the packets to the IPsec engine. With padding stripped, the session can be processed normally by the IPsec engine.

Use the following command to strip ESP padding:

```
config system npu
   set strip-esp-padding enable
   set strip-clear-text-padding enable
```

```
end
```

Stripping clear text and ESP padding are both disabled by default.

Optionally disable NP6 offloading of traffic passing between 10Gbps and 1Gbps interfaces (392436)

Due to NP6 internal packet buffer limitations, some offloaded packets received at a 10Gbps interface and destined for a 1Gbps interface can be dropped, reducing performance for TCP and IP tunnel traffic. If you experience this performance reduction, you can use the following command to disable offloading sessions passing from 10Gbps interfaces to 1Gbps interfaces:

```
config system npu
   set host-shortcut-mode host-shortcut
end
```

Select `host-shortcut` to stop offloading TCP and IP tunnel packets passing from 10Gbps interfaces to 1Gbps interfaces. TCP and IP tunnel packets passing from 1Gbps interfaces to 10Gbps interfaces are still offloaded as normal.

If `host-shortcut` is set to the default `bi-directional` setting, packets in both directions are offloaded.

BFD echo mode support (enable/disable blocking land attacks) (441740)

A new option has been added to FortiOS 5.4.6 that allows you to enable or disable blocking land attacks:

```
config system settings
   set block-land-attack {disable | enable}
end
```

This option is disabled by default. Since its a `system settings` option you can enable or disable blocking land attacks for individual VDOMs if your FortiGate is operating with multiple VDOMs.

Another reason to enable this feature would be if your FortiGate is blocking BFD echo packets that should be allowed to pass through the FortiGate. For example, a FortiGate operating in Transparent mode between two routers with a policy that allows all traffic may block BFD echo communication between the routers if blocking land attacks is disabled.

Enabling blocking land attacks allows BFD echo packets to pass through the FortiGate. Use the following command to block land attacks and allow BFD echo packets.

```
config system settings
   set block-land-attack enable
end
```

Memory compatibility mode for HA between FortiGates of different hardware generations (436585)

Different hardware generations of some FortiGate models may have different amounts of system memory. In HA mode this means the primary unit, if it has more memory than the backup unit, could be able to handle more sessions than the backup unit. So after a failover some sessions could be lost if the backup unit doesn't have enough memory for all of the sessions. If you have a cluster of FortiGates from different hardware generations you can use the following command to enable memory compatibility mode to prevent session loss after a failover. Memory compatibility mode is disabled by default.

```
config system ha
   set memory-compatible-mode {disable | enable}
end
```

Memory compatibility mode synchronizes the memory size among the units in the cluster. The amount of memory available on the FortiGate with the lowest amount of memory is set as the soft total memory for each FortiGate in the cluster. That way, after a failover the new primary unit will have the same amount of memory for processing sessions and will support the same number of sessions as the former primary unit. As a result, after a failover no sessions are lost.

WiFi split tunnel enhancement (413142)

In a WTP profile, you can use the following command to control whether packets that match the split tunneling access control list (ACL) use the CAPWAP tunnel or the local LAN between the FortiAP and the FortiGate.

```
config wireless-controller wtp-profile
   edit <profile-name>
      set split-tunneling-acl-path {tunnel | local}
   end
```

where:

`tunnel` packets from wireless clients that match the split tunneling ACL pass from the FortiAP through the CAPWAP tunnel to the FortiGate (tunnel mode) and then to their destination.

`local` (the default) packets from wireless clients that match the split tunneling ACL pass across the local LAN from the FortiAP to the FortiGate (source NAT applied) and then to their destination.

What's New in FortiOS 5.4.4

Most development work in FortiOS 5.4.4 involved resolving issues. However, there was a new feature as well.

Configure the number of IPsec engines NP6 processors use (370586)

NP6 processors use multiple IPsec engines to acceleration IPsec encryption and decryption. In some cases out of order ESP packets can cause problems if multiple IPsec engines are running. To resolve this problem you can configure all of the NP6 processors to use fewer IPsec engines.

Use the following command to change the number of IPsec engines used for decryption (`ipsec-dec-subengine-mask`) and encryption (`ipsec-enc-subengine-mask`). These settings are applied to all of the NP6 processors in the FortiGate unit.

```
config system npu
   set ipsec-dec-subengine-mask <engine-mask>
   set ipsec-enc-subengine-mask <engine-mask>
end
```

`<engine-mask>` is a hexadecimal number in the range 0x01 to 0xff where each bit represents one IPsec engine. The default `<engine-mask>` for both options is 0xff which means all IPsec engines are used. Add a lower `<engine-mask>` to use fewer engines. You can configure different engine masks for encryption and decryption.

What's New in FortiOS 5.4.3

Most development work in FortiOS 5.4.3 involved resolving issues. However, there was a new feature as well.

FortiGate compatibility with FortiAP-C series (380150, 386116, 383004)

A new command, `fapc-compatibility` under `config wireless-controller setting`, has been added to enable or disable FortiAP-C series management by the FortiGate. Default FortiAP-C wtp-profiles will be added once the command is enabled.

This feature is only available when the command's `country` setting is set to either `CN` (China) or `SG` (Singapore); all other countries are unsupported. This options is disabled by default.

To enable FortiGate compatibility with FortiAP-C, enter the following command:

```
config wireless-controller setting
   set country {CN | SG}
   set fapc-compatibility {enable | disable}
end
```

Note that disabling `fapc-compatibility` will remove all the FAP-C series `wtp-groups`, `wtps`, and `wtp-profiles`.

FortiAP-C series models will become available as supported platform types under `config wireless-controller wtp-profile`, but only when `country` in `wireless-controller setting` and `ap-country` in `wtp-profile` are both set to the same supported country (either China or Singapore).

The following FortiAP-C models are supported platform models for this command: C220C, C225C, C221E, C226E, C23JD, C24JE, and C21D.

To set the platform type, enter the following command:

```
config wireless-controller wtp-profile
   edit <example>
      config platform
         set type <model>
      end
end
```

What's New in FortiOS 5.4.2

Most development work in FortiOS 5.4.2 involved resolving issues. However, there were a few new features as well.

Bootstrapping enabled for FortiGate VM platforms (391527)

All FortiOS 5.4.2 VM platforms support bootstrapping, allowing you to setup an iso file package that simplifies deploying FortiOS VMs. Using bootstrapping you can create a package that includes the VM firmware, a network configuration customized for your network and VM licensing, and other configuration elements such as basic firewall policies. You can then use the iso file to deploy FortiOS VM firmware into your VM environment.

To set up bootstrapping you need a VM license file and a default FortiOS VM configuration file. The configuration file sets up default FortiOS VM settings such as adding a hostname, configuring interfaces and so on.

Components of the config file should be similar to the following:

```
#---------configfirewall.conf-----------
root@KVM-Hypervisor:~/vz-wip# cat FGT_CONFIG_DRIVE/openstack/latest/user_data
```

```
#VM Config File
config system global
   set hostname vFGTvm00
end
config system interface
   edit port1
      set alias "EXT"
      set description "Management Network (DHCP) eth0br"
      set allowaccess ping https ssh fgfm
      set mode dhcp
   next
   edit port2
      set alias "Internal"
      set description "Liveliness Network (Static) gluebr0"
      set allowaccess ping https ssh fgfm
      set ip 192.168.1.10/24
   next

config firewall policy
   edit 0
      set name "Allow any any"
      set srcintf "port2"
      set dstintf "port1"
      set srcaddr "all"
      set dstaddr "all"
      set action accept
      set schedule "always"
      set service "ALL"
      set nat enable
   next
end

config sys dns
   set primary 8.8.8.8
   unset secondary
end

config sys global
   set hostname fgt-vm-workshop
end
```

Then create a configuration file used to build the iso file, for example:

```
{
"bucket" : "confftnt",
"region" : "us-west-2",
"license" : "/FGVM080000066848.lic",
"config" : "/configfirewall.conf",
}
```

ISO Structure

It is also important that the ISO have similar structure and permissions to the following:

The user account of the intaller has been replaced with `<user_account>`.

```
<user_account>:iso <user_account>$ ll -R
total 8
```

```
drwxr-xr-x 1 <user_account> staff 2048 Jan 20 15:14 .
drwxr-xr-x@ 8 root wheel 272 Jan 23 10:07 ..
drwxr-xr-x 1 <user_account> staff 2048 Jan 20 14:53 openstack
.
.
.

./openstack:
total 16
drwxr-xr-x 1 <user_account> staff 2048 Jan 20 14:53 .
drwxr-xr-x 1 <user_account> staff 2048 Jan 20 15:14 ..
drwxr-xr-x 1 <user_account> staff 2048 Jan 20 14:53 content
drwxr-xr-x 1 <user_account> staff 2048 Jan 20 14:54 latest
.
.
.

./openstack/content:
total 12
drwxr-xr-x 1 <user_account> staff 2048 Jan 20 14:53 .
drwxr-xr-x 1 <user_account> staff 2048 Jan 20 14:53 ..
-rwxr-xr-x 1 <user_account> staff 287 Jan 19 16:02 0000
.
.
.
./openstack/latest:
total 12
drwxr-xr-x 1 <user_account> staff 2048 Jan 20 14:54 .
drwxr-xr-x 1 <user_account> staff 2048 Jan 20 14:53 ..
-rwxr-xr-x 1 <user_account> staff 813 Jan 19 16:02 user_data
.
.
.
```

Where “0000” has the following content:

```
<user_account>:iso <user_account>$ cat openstack/content/0000
-----BEGIN FGT VM LICENSE-----
QAAAAFS1V9CLl8h69qtDbikc4yW8hSi0kyFBlFi1LqQlqXG59uCLSlJiGfHt6ddbweM0d3guoeu

-----END FGT VM LICENSE-----
```

FortiAP-421E and 423E and wave 2 WiFi support (371374)

FortiOS 5.4.2 includes FortiAP profiles for the FortiAP-421E and FortiAP-423E and these profiles include support for Wave 2 WiFi.

Dynamic Frequency Selection (DFS) support added (369052)

DFS support has been added for FortiAP models that support it. FortiAP models that support this feature include the 321C, 323C, 421E, S421E, 423E, S423E, and S422E.

BGP local-AS support (307530)

Use the following command to configure BGP local-AS support:

```
config router bgp
   config neighbor
      edit "neighbor"
         ...
         set local-as 300
         set local-as-no-prepend disable|enable
         set local-as-replace-as disable|enable
      end
```

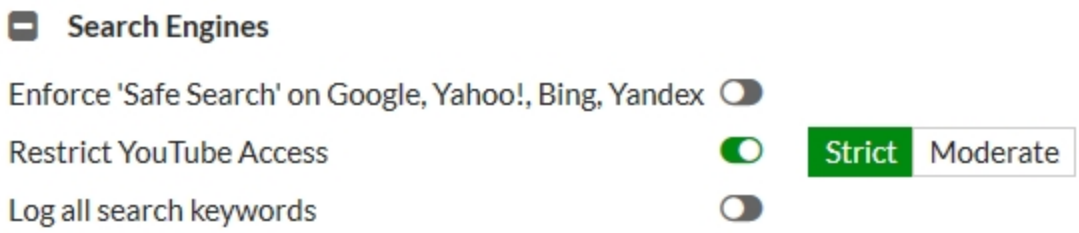
Enable `local-as-no-prepend` if you do not want to prepend local-as to incoming updates.

Enable `local-as-replace-as` to replace a real AS with local AS in outgoing updates.

Restricting access to YouTube (replacement for the YouTube Education filter feature) (378277)

Previous versions of FortiOS supported YouTube for Schools (YTfS). As of July 1, 2016 this feature is no longer supported by YouTube. Instead you can use the information in the YouTube support article Restrict YouTube content on your network or managed devices to achieve the same result. FortiOS supports applying **Strict** or **Moderate** restrictions using HTTP headers as described in this article.

In FortiOS 5.4.2 with inspection mode set to proxy-based, in a Web Filter profile under **Search Engines** you can select **Restrict YouTube Access** and select either **Strict** or **Moderate**.



High Availability hello-holddown CLI option typo fix (382364)

The `config system ha` option `helo-holddown` has been renamed `hello-holddown`.

DNS filter available in flow mode (390957)

DNS filter security profiles can now be edited and added to security policies if the FortiGate or the current VDOM Inspection Mode is set to Flow-based.

Patch apache server vulnerabilities (379870)

The following CLI commands have been added as part of an update to protect SSL VPN connections to the FortiGate from Slowloris (CVE-2007-6750) and R-U-Dead-Yet attacks.

```
config vpn ssl settings
   set http-request-header-timeout 20
   set http-request-body timeout 30
end
```

`http-request-header-timeout` protects against Slowloris by controlling maximum time to read the HTTP request header. If the HTTP header does not complete within this time, SSL VPN disconnects the connection with response code 408 (Request Timeout). The default is 20 seconds and the range is 1 to 60 seconds.

`http-request-body-timeout` protects against R-U-Dead-Yet attacks by controlling the maximum time to read a HTTP request body. If the HTTP body does not complete within this time, SSL VPN disconnects the connection with response code 408 (Request Timeout). The default is 30 seconds and the range is 1 to 60 seconds.

Diagnose hardware test added to select FortiGate models (388646 302021 381208)

Most current FortiGate models include the `diagnose hardware test` command that you can use to test all aspects of a FortiGate's hardware and report on problems that are found.

Antispam log message improvements (284055)

When Antispam protection finds a phishing URL in an email message, the log message recorded for this event now includes the phishing URL found in the email message. The phishing URL is included in the `fortiguardresp` log message field.

Last session information saved in a crash log when an IPS engine crash occurs (378252)

Changes to FortiOS IPS and to the IPS engine version 3.170 now cause FortiOS to save a crash log with the last session information when an IPS crash occurs. This information can be used by Fortinet support to diagnose the cause of the crash.

Cooperative Security Fabric (CSF)

In FortiOS 5.4.1, new features were added allowing a FortiGate to be configured as part of a Cooperative Security Fabric (CSF). A CSF links different security sensors and tools together in order to collect, coordinate, and respond to malicious behavior anywhere it occurs in real time.

Multiple VDOM support is disabled when CSF is enabled.

Fortinet Cookbook Recipe Collection

To demonstrate how to configure a CSF, the Cooperative Security Fabric collection has been published on the Fortinet Cookbook website. This collection will be added to over time, so check back to see if anything new has been added.

Cooperative Security Fabric Menu

The Cooperative Security Fabric menu can be found at **System > Cooperative Security Fabric**. From here you can enable CSF on the FortiGate and, if necessary, configure the FortiGate to connect to an upstream FortiGate.

CSF FortiView Dashboards

Two new FortiView dashboards have been added to display information about a CSF. The **Physical Topology** dashboard shows all access layer devices, while the **Logical Topology** dashboard displays information about

the interface (logical or physical) that each device is connected to.

FortiTelemetry

FortiTelemetry is a protocol, similar to the FGCP heartbeat, used for communication between different Fortinet products. It is used to connect devices in a CSF, to support On-Net functionality, and monitor and enforce FortiClient use for devices on a network protected by FortiOS.

FortiTelemetry must be enabled on interfaces that connect devices in the CSF.

External Security Devices

External Security Devices can be configured as means to offload processes to other devices, such as a FortiWeb, FortiCache, or FortiMail. Example processes could include HTTP inspection, web caching, and anti- spam.

Offloading HTTP traffic to FortiWeb

Use the following steps to offload HTTP traffic to FortiWeb to apply Web Application Firewall features to the traffic. Using these steps you can select the HTTP traffic to offload by adding a web application firewall profile configured for external inspection to selected firewall policies. Only the HTTP traffic accepted by those firewall policies is offloaded.

If you offload HTTP traffic to FortiWeb you can also apply other HTTP inspection to it from your FortiGate including virus scanning and web filtering.

A single FortiGate cannot offload HTTP traffic to both FortiCache and FortiWeb.

To offload HTTP traffic to FortiWeb:

1. Go to the **System Information** dashboard widget and make sure **Inspection Mode** is set to **Proxy-based**.
2. Go to **System > Feature Select** and turn on **Web Application Firewall**.
3. Go to **System > Cooperative Security Fabric**, enable **HTTP Service**, select **FortiWeb** and add the IP addresses of your FortiWeb devices. You can also select **Authentication** add a **password** if required.
4. Go to **Security Profiles > Web Application Firewall** and add or edit a Web Application Firewall profile and set **Inspection Device** to **External**.
5. Go to **Policy & Objects > IPv4 Policy**, add or edit a firewall policy, select **Web Application Firewall**, and select the profile that you set to use the external inspection device.

These steps add the following configuration to the CLI:

```
config system wccp
   set service-id 51
   set router-id 5.5.5.5 (the IP address of the FortiGate interface that communicates with
       the FortiWeb)
   set group address 0.0.0.0
   set server-list 5.5.5.25 255.255.255.255 (the IP address of the FortiWeb)
   set authentication enable
   set forward-method GRE
   set return-method GRE
   set assignment-method HASH
   set password *
end
```

Offloading HTTP traffic to FortiCache

To offload Web Caching to FortiCache a FortiGate must support WAN Optimization and WAN Optimization must be enabled. For some FortiGate models you need to turn off disk logging to support WAN Optimization. See "WAN Optimization" on page 218 in What's New for details.

Use the following steps to offload web caching to FortiCache. Using these steps you can select the web traffic to offload by selecting web caching in firewall policies. Only the web traffic accepted by those firewall policies will be offloaded.

A single FortiGate cannot offload HTTP traffic to both FortiCache and FortiWeb.

1. Go to the **System Information** dashboard widget and make sure **Inspection Mode** is set to **Proxy-based**.
2. Go to **System > Advanced > Disk Settings** and assign at least one disk to **WAN Optimization**.
3. Go to **System > Feature Select** and turn on **WAN Opt. & Cache**.
4. Go to **System > Cooperative Security Fabric**, enable **HTTP Service**, select **FortiCache** and add the IP addresses of your FortiCache devices. You can also select **Authentication** add a **password** if required.
5. Go to **Policy & Objects > IPv4 Policy**, add or edit a firewall policy and select **Web Cache**.

These steps add the following configuration to the CLI:

```
config system wccp
   set service-id 51
   set router-id 5.5.5.5 (the IP address of the FortiGate interface that communicates with
       the FortiCache)
   set group address 0.0.0.0
   set server-list 5.5.5.45 255.255.255.255 (the IP address of the FortiCache)
   set authentication enable
   set forward-method GRE
   set return-method GRE
   set assignment-method HASH
   set password *
end
```

Offloading SMTP traffic to FortiMail

Use the following steps to offload SMTP traffic to FortiMail to apply FortiMail features to the traffic. Using these steps you can select the SMTP traffic to offload by adding an AntiSpam profile configured for external inspection to selected firewall policies. Only the SMTP traffic accepted by those firewall policies is offloaded.

If you offload HTTP traffic to FortiWeb you can also apply other HTTP inspection to it from your FortiGate including virus scanning and web filtering.

To be able to offload Anti-Spam processing to a FortiMail device you should:

1. Go to the **System Information** dashboard widget and make sure **Inspection Mode** is set to **Proxy-based**.
2. Go to **System > Feature Select** and turn on **Anti-Spam Filter**.
3. Go to **System > Cooperative Security Fabric**, enable **SMTP Service - FortiMail** and add the IP address of your FortiMail devices. You can also select **Authentication** add a **password** if required.
4. Go to **Security Profiles > Anti-Spam** and edit an Anti-Spam profile and set **Inspection Device** to **External**.
5. Go to **Policy & Objects > IPv4 Policy**, add or edit a Firewall policy, enable **Anti-Spam** and select the profile for which you set Inspection Device to External.

These steps add the following configuration to the CLI:

```
config system wccp
   set service-id 52
```

```
    set router-id 5.5.5.5 (the IP address of the FortiGate interface that communicates with
        the FortiMail)
    set group address 0.0.0.0
    set server-list 5.5.5.65 255.255.255.255 (the IP address of the FortiMail)
    set authentication enable
    set forward-method GRE
    set return-method GRE
    set assignment-method HASH
    set password *
end
```

Policy Learning Mode

Learning mode for Firewall policies (310544 365727)

The learning mode feature is a quick and easy method for setting a policy to allow everything but to log it all so that it can later be used to determine what restrictions and protections should be applied. The objective is to monitor the traffic not act upon it while in Learning mode.

Once the **Learn** action is enabled, functions produce hard coded profiles that will be enabled on the policy. The following profiles are set up:

- AntiVirus (`av-profile`)
- Web Filter (`webfilter-profile`)
- Anti Spam(`spamfilter-profile`)
- Data Leak Prevention (`dlp-sensor`)
- Intrusion Protection (`ips-sensor`)
- Application Control (`application-list`)
- Proxy Options (`profile-protocol-options`)

- These UTM profiles are all using Flow mode
- SSL inspection is always disable for the Learn option
- These profiles are static and cannot be edited.

Profiles that are not being used are:

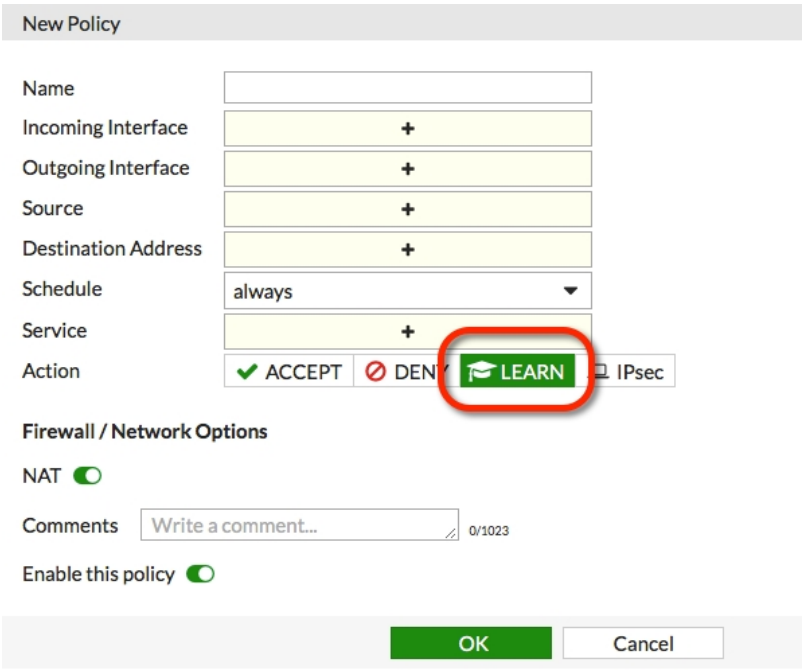
- DNS Filter (Does not have a Flow mode)
- Web Application Firewall(Does not have a Flow mode)
- CASI(Almost all signatures in CASI require SSL deep inspection. Without SSL inspection, turning on CASI serves little purpose)

The ability to allow policies to be set to a learning mode is enabled on a per VDOM basis.

```
config system settings
   set gui-policy-learning [enable | disable]
   end
```

Once the feature is enabled on the VDOM, Learn is an available **Action** option when editing a policy.

Because this feature requires a minimum level of logging capabilities, it is only available on FortiGates with hard drives. Smaller models may not be able to use this feature.



Once the Learning policy has been running for a sufficient time to collect needed information a report can be looked at by going to **Log & Report > Learning Report**.

The Report can be either a **Full Report** or a **Report Summary**

The time frame of the report can be **5 minutes**, **1 hour**, or **24 hours**.

The Learning Report includes:

Deployment Methodology

- Test Details
  - Start time
  - End time
  - Model
  - Firmware
- Policy List

Executive Summary

- Total Attacks Detected
- Top Application Category
- Top Web Category
- Top Web Domain
- Top Host by Bandwidth
- Host with Highest Session Count

Security and Threat Prevention

- High Risk Applications
- Application Vulnerability Exploits
- Malware, botnets and Spyware/Adware
- At-Risk Devices and Hosts

User Productivity

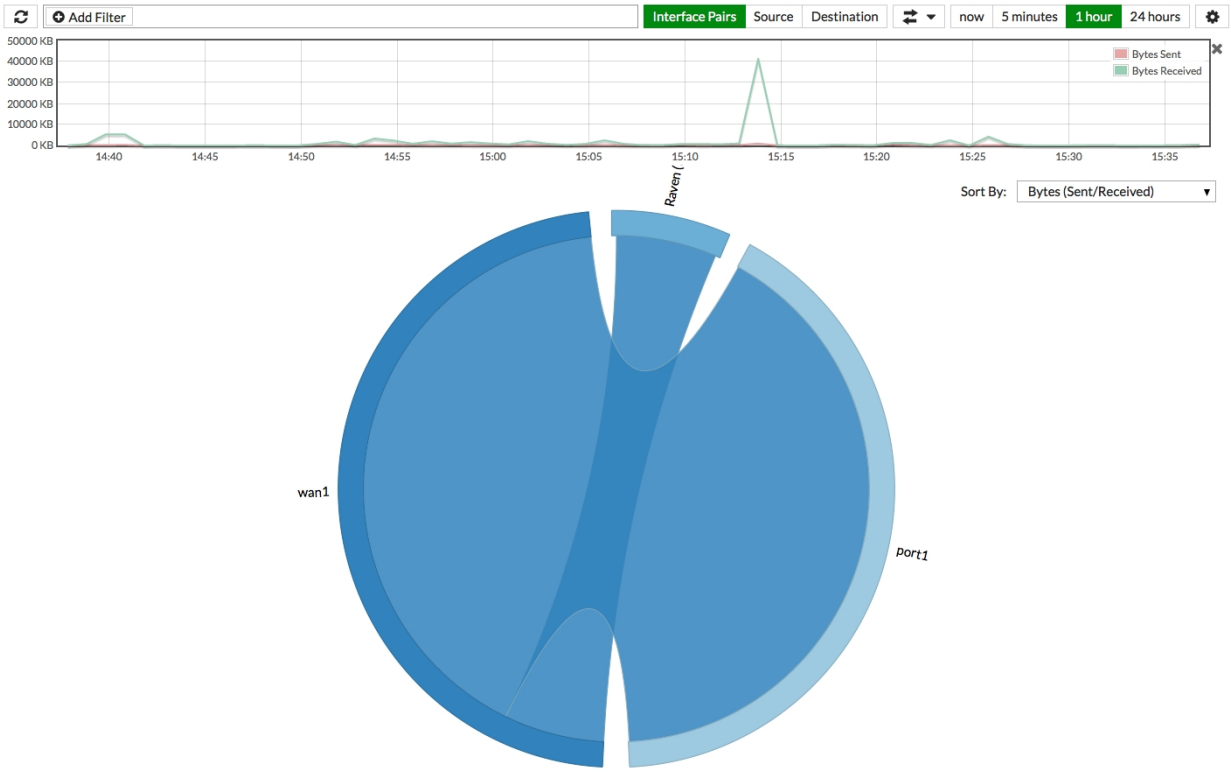
- Application Usage
  - Top Application Categories
  - Top Social Media Applications
  - Top Video/Audio Streaming Applications
  - Top Peer to Peer Applications
  - Top Gaming Applications
- Web Usage
  - Top Web Categories
  - Top Web Applications
  - Top Web Domains

FortiView

This chapter describes new FortiView features added to FortiOS 5.4.

New Interface Pair Visualization

A new visualization has been added to FortiView on the **Interfaces** page, with a cord chart showing which interfaces are connecting to each other, with comparative traffic volumes.



Notes about the Interface Pair Chart:

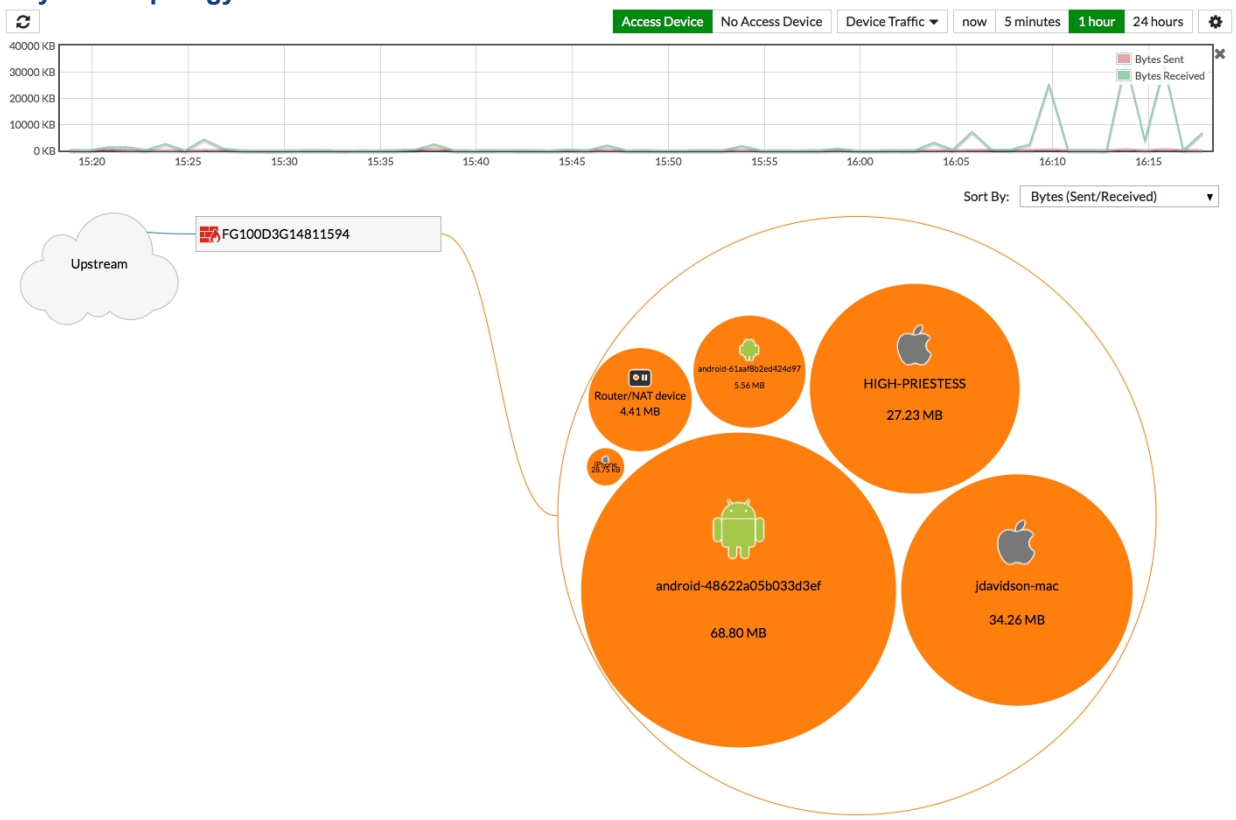
- It is possible to sort the Interface Pair Chart using the **Sort By:** dropdown menu.
- The width of each edge of the ring represents the volume of traffic.
- Place your cursor over an interface on the edge of the ring to hide all the other connections.
- You can mouse over the connecting cord to see a detail popup.

New Cooperative Security Fabric charts in FortiView (286116 308676)

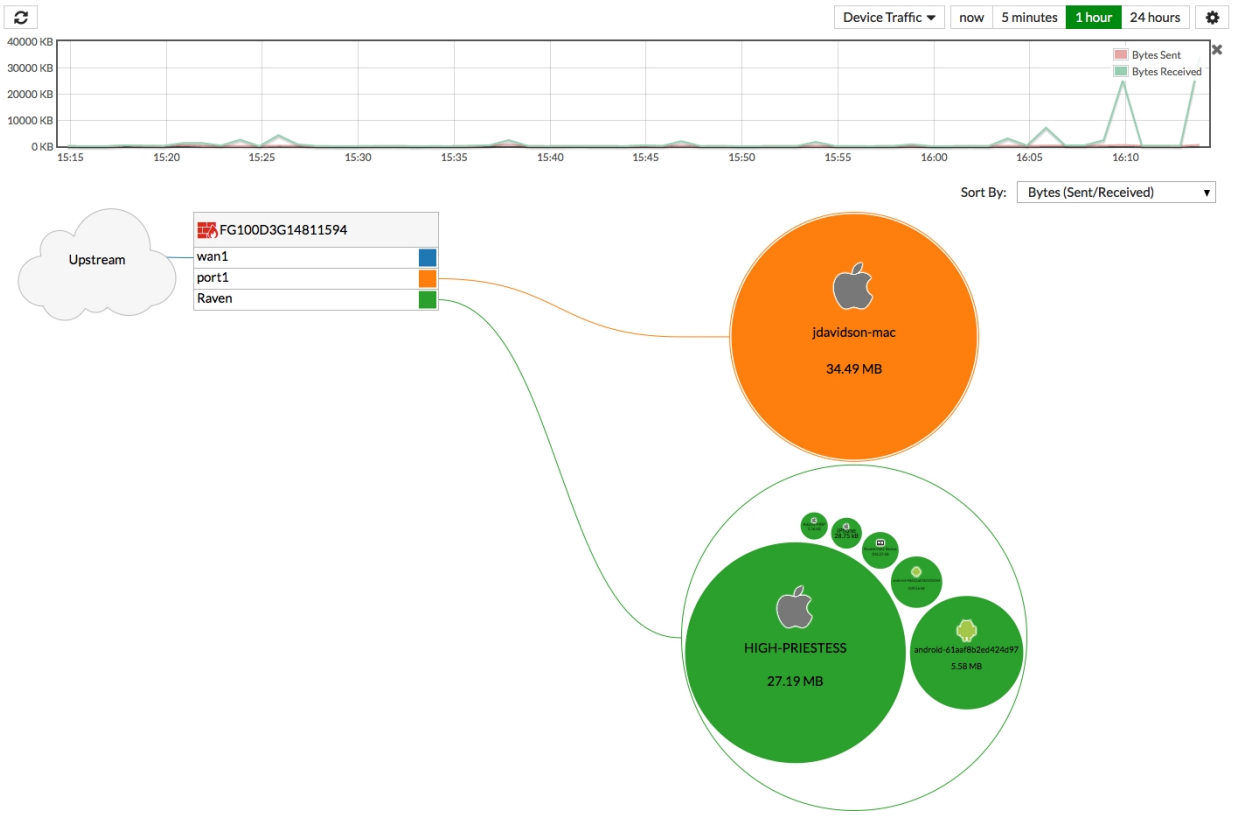
FortiOS 5.4.1 integrates the new Cooperative Security Fabric (CSF) features, which allow you greater control and oversight over your integrated network. For more on Cooperative Security Fabric, read the What's New section on CSF.

FortiView has integrated two new charts to support CSF in 5.4.1: **Physical Topology** and **Logical Topology**. They are scaled bubble charts that show the logical structure of your network, with upstream and downstream devices organized by connection.

Physical Topology



Logical Topology



Notes about the Topology Charts:

- It is possible to sort the Topology Charts using the **Sort By:** dropdown menu.
- You can customize what the bubble size represents with the dropdown next to the time selection.
- In Physical Topology, you can mouse over the bubbles and devices for overall device information.
- In Logical Topology, you can mouse over the bubbles and device ports for more detailed connection information.

FortiOS now supports more detailed geographic information (310567)

More granular city/town information has been added to the log system. It is not used in the management interface in 5.4.1, but is available in the CLI, with the command `diag geoip ip2country`.

New Search Phrases list available on the Web Sites page (303437)

FortiGate models 1500D and above now support 7-day view in FortiView (264331)

IPv6 policies appear in realtime FortiView displays (277558)

New Consoles

In FortiOS 5.4, a variety of new consoles have been added to FortiView:

FortiView Policies console

The new **Policies** console works similarly to other FortiView consoles, yet allows administrators to monitor policy activity, and thereby decide which policies are most and least active. This helps the administrator to discern which policies are unused and can be deleted.

In addition, you have the ability to click on any policy in the table to drill down to the Policies list and view or edit that policy. You can view this new console in either Table or Bubble Chart view.

FortiView Interfaces console

The new **Interfaces** console works similarly to other FortiView consoles and allows administrators to perform current and historical monitoring per interface, with the ability to monitor bandwidth in particular. You can view this new console in either Table or Bubble Chart view.

FortiView Countries console

A new **Countries** console has been introduced to allow administrators to filter traffic according to source and destination countries. This console includes the option to view the Country Map visualization (see below).

FortiView Device Topology console

The new **Device Topology** console provides an overview of your network structure in the form of a Network Segmentation Tree diagram (see below).

FortiView Traffic Shaping console

A new **Traffic Shaping** console has been introduced to improve monitoring of existing Traffic Shapers.

Information displayed includes Shaper info, Sessions, Bandwidth, Dropped Bytes, and more.

FortiView Threat Map console

A new **Threat Map** console has been introduced to monitor risks coming from various international locations arriving at a specific location, depicted by the location of a FortiGate on the map (see below).

FortiView Failed Authentication console

A **Failed Authentication** console has been added under **FortiView** that allows you to drill down an entry to view the logs. This new console is particularly useful in determining whether or not the FortiGate is under a brute force attack. If an administrator sees multiple failed login attempts from the same IP, they could (for example) add a local-in policy to block that IP.

The console provides a list of unauthorized connection events in the log, including the following:

- unauthorized access to an admin interface (telnet, ssh, http, https, etc.)
- failure to query for SNMP (v3) or outside of authorized range (v1, v2, v3)
- failed attempts to establish any of the following:
  - Dial-up IPsec VPN connections
  - Site-to-site IPsec VPN connections
  - SSL VPN connections
  - FGFM tunnel

FortiView WiFi Clients console

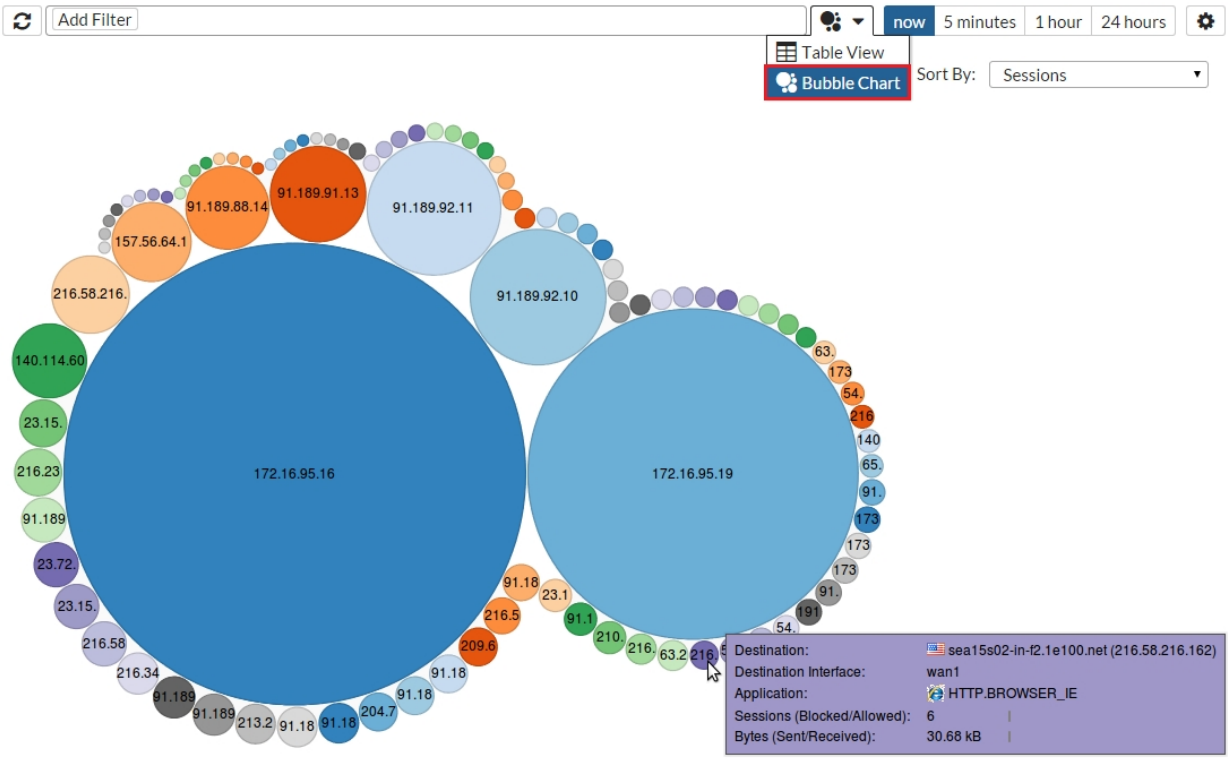
The WiFi Clients console has been added to FortiView in FortiOS 5.4. As you might expect, you can use this console to display top wireless user network usage and information. You can drilldown to filter the information that is displayed.

Information displayed includes Device, Source IP, Source SSID, AP, and more.

New FortiView Visualizations

New visualization support has been added to FortiView via the Bubble Chart and the Country Map.

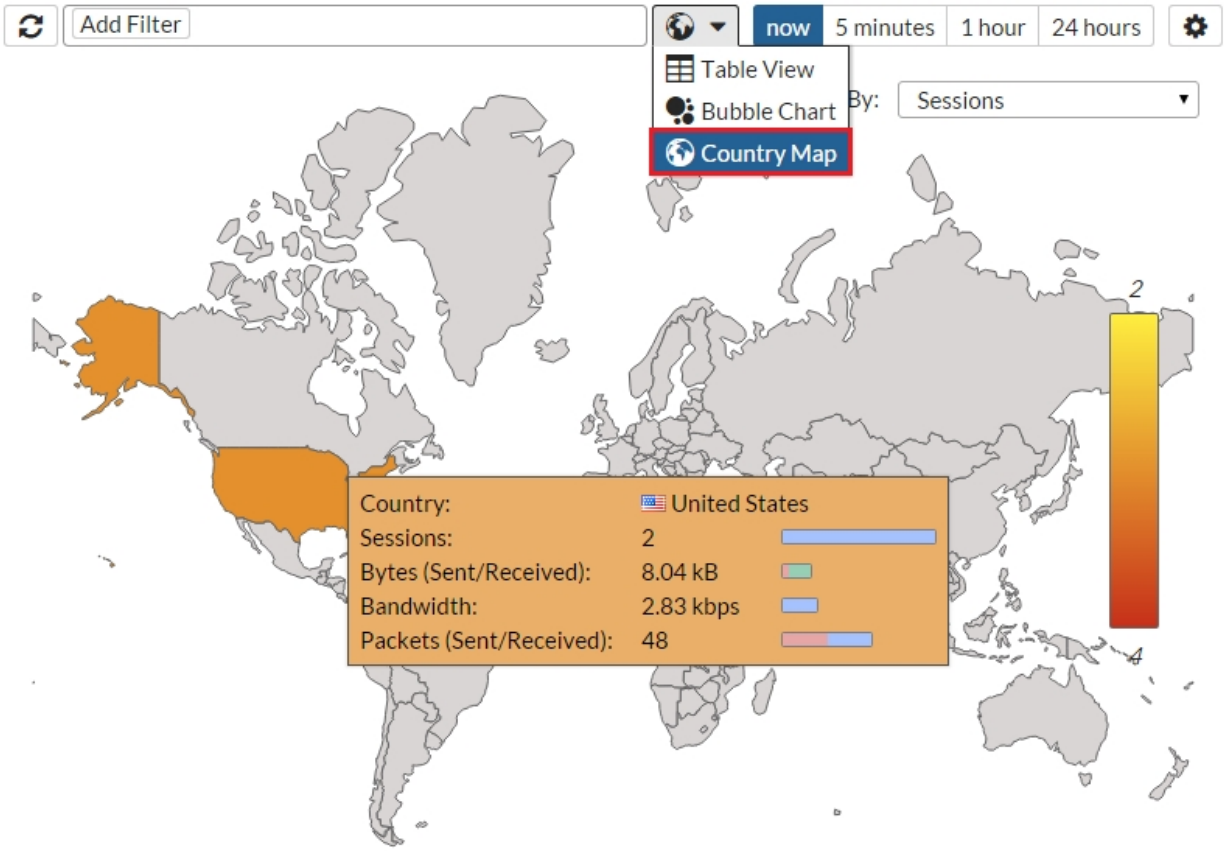
Bubble Chart Visualization



Notes about the Bubble Chart:

- It is possible to sort on the Bubble Chart using the **Sort By:** dropdown menu.
- The size of each bubble represents the related amount of data.
- Place your cursor over a bubble to display a tool-tip with detailed info on that item.
- You can click on a bubble to drilldown into greater (filtered) detail.

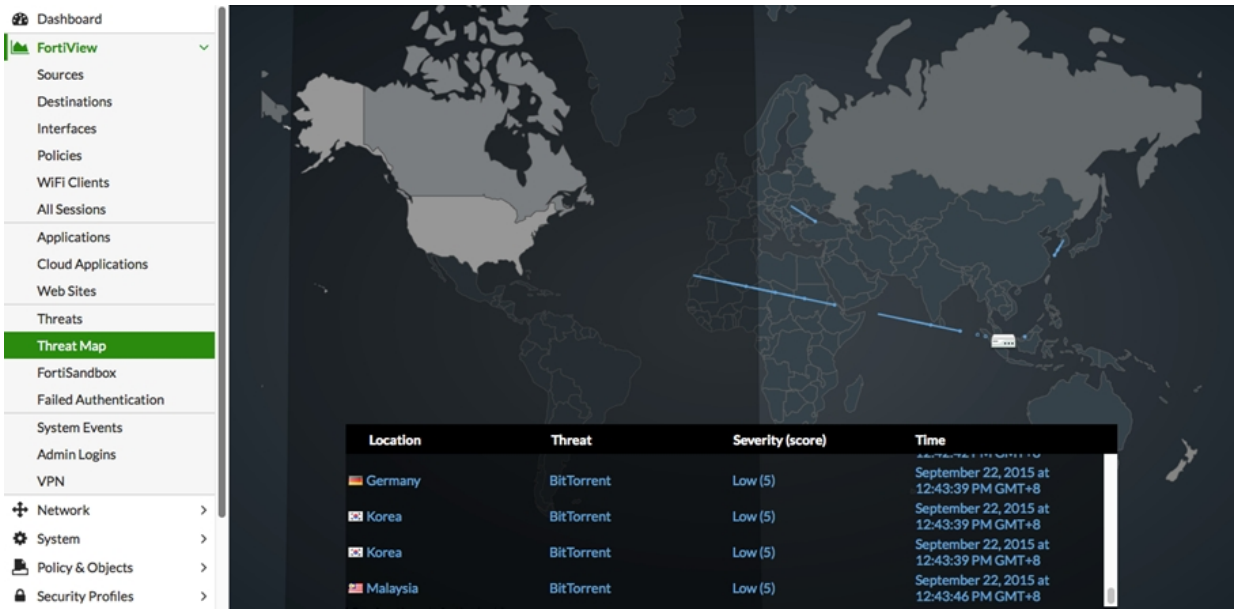
Country Map Visualization



Notes about the Country Map:

- The Country Map is only available in the Countries dashboard.
- It is possible to sort on the Country Map using the **Sort By:** dropdown menu.
- Place your cursor over any country to display a tool-tip with detailed info on that country's traffic.
- The colour gradiant on the map indicates the traffic load, where red indicates the more critical load.
- Click on any country to drilldown into greater (filtered) detail.

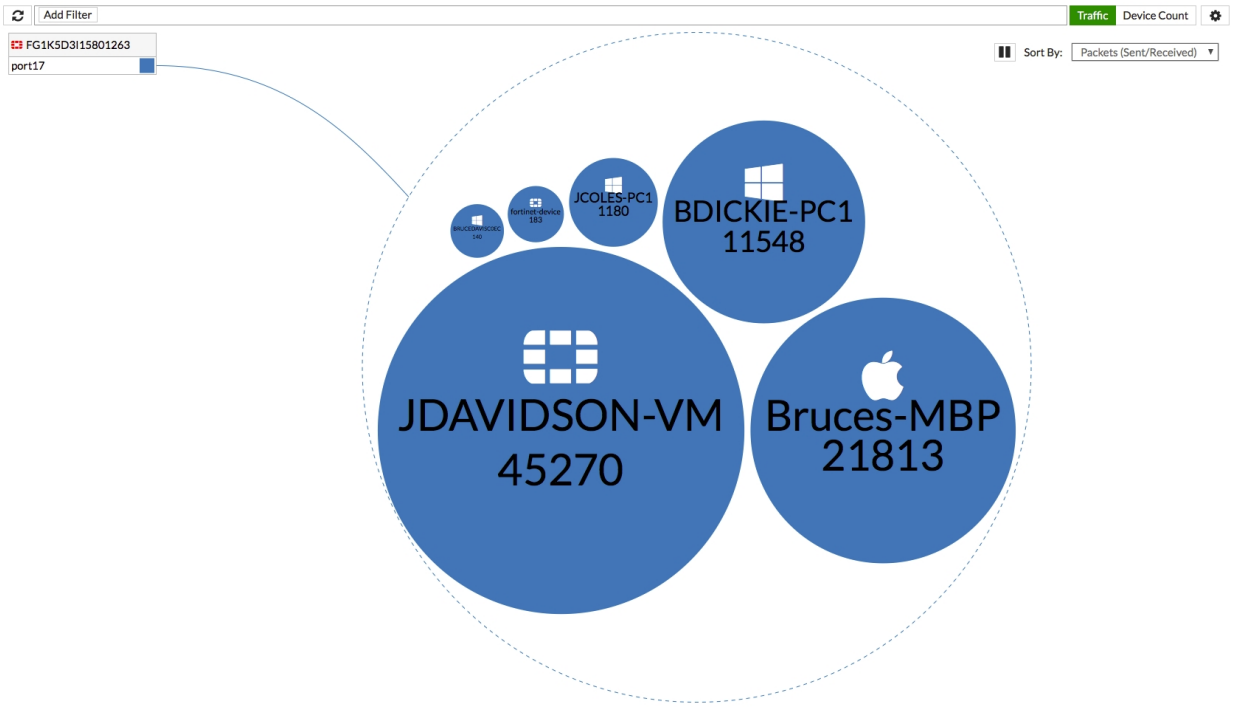
Threat Map Visualization



Notes about the Threat Map:

- Threats from various international destinations will be shown, but only those arriving at your destination, as depicted by the FortiGate.
- Place your cursor over the FortiGate's location to display the device name, the IP address, and the city name/location.
- A visual lists of threats is shown at the bottom, displaying the location, severity, and nature of the attacks.
- The colour gradiant of the darts on the map indicate the traffic risk, where red indicates the more critical risk.
- Click on any country to drilldown into greater (filtered) detail.

Device Topology Visualization



Notes about Device Topology:

- Place your cursor over any object in the visualization to display the device name, the IP address, Sessions, sent and received Bytes and Packets, Bandwidth, and Dropped Bytes.
- In many cases, such as Internal Network Firewall (INFW) deployments, there are multiple Fortigates performing NAT before a host reaches the external-facing WAN. In such a situation, a bubble chart depicting internal traffic may be inaccurate because the biggest bubble will be a Fortigate that is NAT'ing hundreds of endpoints behind it. This page solves that issue by ensuring all network elements are given visibility and structured in a human-readable format.

Realtime visualization

In addition to these new visualization options, you can now also enable realtime visualization.

To enable realtime visualization:

1. Click on the **Settings** icon next to the upper right-hand corner and select **Auto update realtime visualizations**. An option is displayed to set the **Interval (seconds)**. The maximum value is 300.
2. Enter a desired **Interval** and click **Apply**.

Links created between FortiView and View/Create Policy

The **Policy** column in FortiView consoles and the Log Viewer pages has changed to a link, which navigates to the IPv4 or IPv6 policy list and highlights the policy.

Right-clicking on a row in FortiView or the Log Viewer has menu items for **Block Source**, **Block Destination** and **Quarantine Source** where appropriate columns are available to determine these values. When multiple rows are selected, the user will be prompted to create a named **Address Group** to contain the new addresses.

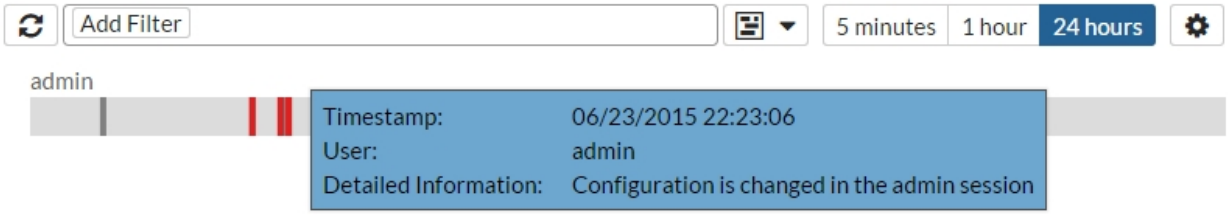
When the user clicks **Block Source** or **Block Destination** they are taken to a policy creation page with enough information filled in to create a policy blocking the requested IP traffic.

The policy page will feature an informational message block at the top describing the actions that will be taken. Once the user submits the form, the requisite addresses, groups and policy will be created at once.

If the user clicks on **Quarantine User** then they will be prompted for a duration. They may also check a box for a **Permanent Ban**. The user can manage quarantined users under **Monitor > User Quarantine Monitor**.

Visualization support for the Admin Logins page

A useful chart is now generated for Admin login events under **FortiView > Admin Logins**. You can view the information in either **Table View** or **Timeline View** (shown below). In Timeline View, each line represents on administrator, with individual sessions indicated per administrator line. When you hover over a particular timeline, detailed information appears in a tooltip.



New bandwidth column added to realtime FortiView pages

The FortiView console provides a new bandwidth column that displays information for bandwidth calculated on a per-session level, providing administrators the ability to sort realtime bandwidth usage in descending order.

Accelerated session filtering on All Sessions page

By default, on a FortiGate unit with NP6 processors, when you enable traffic logging in a firewall policy this also enables NP6 per-session accounting. If you disable traffic logging this also disables NP6 per-session accounting. This behavior can be changed using the following command:

```
config system np6
   edit np6_0
      set per-session-accounting {disable | all-enable | enable-by-log}
   end
```

By default, `per-session-accounting` is set to `enable-by-log`, which results in per-session accounting being turned on when you enable traffic logging in a policy. This configuration is set separately for each NP6 processor.

When offloaded sessions appear on the FortiView All Sessions console they include an icon identifying them as NP sessions:

Application	Bytes (Sent/Received)	Policy
TCP/443	29.16 kB	Local In
YouTube	NP 219.44 kB	my-policy
UDP/53	31.05 kB	Local In

You can hover over the NP icon to see some information about the offloaded sessions.

You can also use a FortiASIC Filter to view just the accelerated sessions.

WHOIS Lookup anchor for public IPv4 addresses

Reverse IP lookup is now possible in FortiOS 5.4. A WHOIS lookup icon is available when you mouse over a public IP address in a FortiView log. If you left-click on the lookup icon, a new tab is opened in your browser for www.networksolutions.com, and a lookup is performed on the selected IP address (this option persists after drilling down one level in FortiView).

FortiGuard Cloud App DB identification

FortiView now recognizes FortiGuard Cloud Application database traffic, which is mainly monitored and validated by FortiFlow, an internal application that identifies cloud applications based on IP, Port, and Protocol. Administrators can potentially use this information for WAN Link Load Balancing, for example.

7-day time display

In FortiOS 5.4, the following FortiGate models now support 7-day time display:

- FortiGate 1000D
- FortiGate 1500D
- FortiGate 3700DX
- FortiGate 3700D

The option for 7-day time display, however, can only be configured in the CLI using the following command:

```
config log setting
   set fortiview-weekly-data {enable|disable}
end
```

NP4 and NP6 icons showing accelerated sessions (282180)

When viewing sessions in the All Sessions console, information pertaining to NP4/ NP6 acceleration is now reflected via an appropriate icon. The tooltip for the icon includes the NP chip type and its total number of accelerated sessions.

Filtering on accelerated sessions (282180)

In addition to NP4/NP6 icons, you can now filter the console on 'FortiASIC' ('Accelerated' versus 'Not Accelerated') sessions.

WHOIS Lookup anchor for public IPv4 addresses (282701)

Reverse IP lookup is now possible in FortiOS 5.4. A WHOIS lookup icon is available when you mouse over a public IP address in a FortiView log. If you left-click on the lookup icon, a new tab is opened in your browser for www.networksolutions.com, and a lookup is performed on the selected IP address (this option persists after drilling down one level in FortiView).

New Report database construction (280398 267019)

This will improve performance with reports and FortiView without requiring any configuration changes.

Added a Timeline graph for admin events (271389)

Improved monitoring of traffic shapers; added traffic shaping to FortiView (290363)

Failed Authentication Attempts are now visible in FortiView (265890)

Added bandwidth column to FortiView (260896)

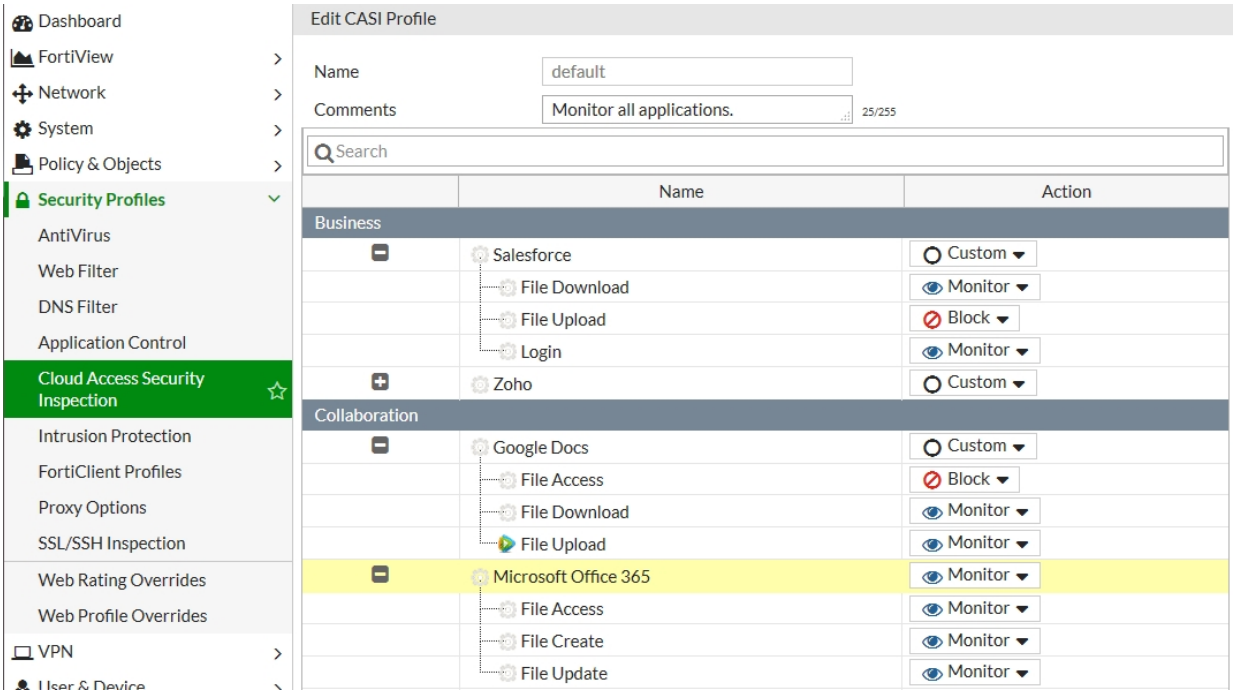
FortiView now displays Quarantine Source and appropriate icon in lists (289206)

Cloud Access Security Inspection (CASI)

Cloud Access Security Inspection (CASI)

This feature introduces a new security profile called Cloud Access Security Inspection (CASI) that provides support for fine-grained control on popular cloud applications, such as YouTube, Dropbox, Baidu, and Amazon. The CASI profile is applied to a policy much like any other security profile.

Unfortunately CASI does not work when using Proxy-based profiles for AV or Web filtering for example.
Make sure to only use Flow-based profiles in combination with CASI on a specific policy.



For this feature, **Deep Inspection of Cloud Applications** (`set deep-app-inspection [enable|disable]`) has been moved out of the **Application Control** security profile options.

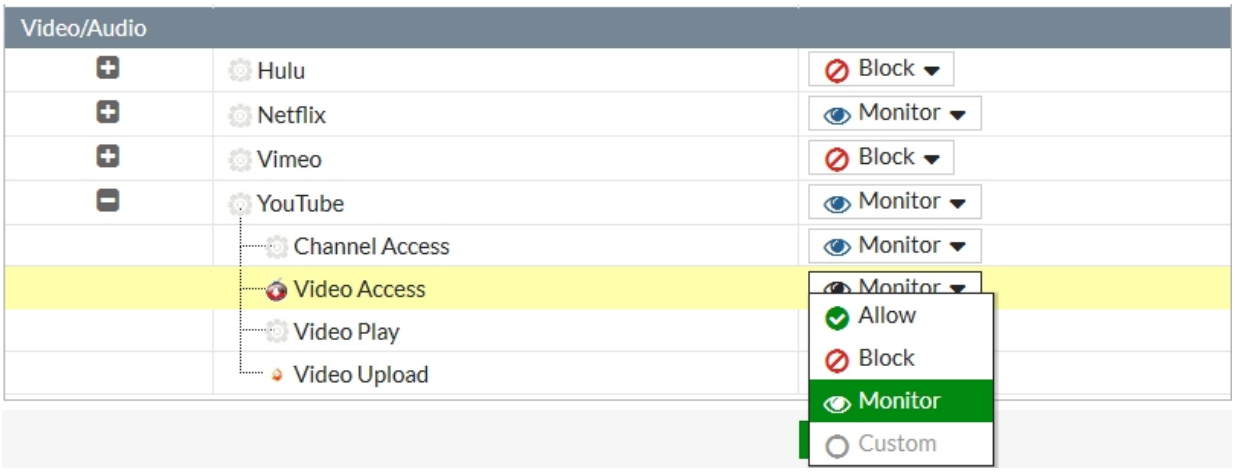
You will find the Cloud Access Security Inspection feature under **Security Profiles > Cloud Access Security Inspection**, but you must first enable it in the Feature store under **System > Feature Select > CASI**.

Editing CASI profiles

The CASI profile application list consists of the **Name**, **Category**, and **Action**. A default CASI profile exists, with the option to create custom profiles.

There is an **improvement to the CASI GUI (303760)** under release 5.4.1. When you search for a profile application to edit, you can hit enter after typing your search terms to see the results. Under release 5.4.0, hitting enter causes the screen to refresh and the profile to be applied.

For each CASI profile application, the user has the option to **Allow**, **Block**, or **Monitor** the selected cloud application. The following image demonstrates the ability to **Allow**, **Block**, or **Monitor** YouTube using CASI:



When the user drills down into a selected cloud application, the following options are available (depending on the type of service):

- **For business services, such as Salesforce and Zoho:** Option to allow, block, or monitor file download/upload and login.
- **For collaboration services, such as Google.Docs and Webex:** Option to allow, block, or monitor file access/download/upload and login.
- **For web email services, such as Gmail and Outlook:** Option to allow, block, or monitor attachment download/upload, chat, read/send message.
- **For general interest services, such as Amazon, Google, and Bing:** Option to allow, block, or monitor login, search phase, and file download/upload.
- **For social media services, such as Facebook, Twitter, and Instagram:** Option to allow, block, or monitor chat, file download/upload, post, login.
- **For storage backup services, such as Dropbox, iCloud, and Amazon Cloud Drive:** Option to allow, block, or monitor file access/download/upload and login.
- **For video/audio services, such as YouTube, Netflix, and Hulu**:
  Option to allow, block, or monitor channel access, video access/play/upload, and login.

CLI Syntax

```
configure application casi profile
   edit "profile name"
      set comment "comment"
      set replacemsg-group "xxxx"
      set app-replacemsg [enable|disable]
```

```
      configure entries
         edit
            set application "app name"
            set action [block|pass]
            set log [enable|disable]
         next
         edit 2
   next
end

configure firewall policy
   edit "1"
      set casi-profile "profile name"
   next
end

config firewall sniffer
   edit 1
      set casi-profile-status [enable|disable]
      set casi-profile "sniffer-profile"
   next
end

config firewall interface-policy
   edit 1
      set casi-profile-status [enable|disable]
      set casi-profile "2"
   next
end
```

Managed FortiSwitch

This chapter describes new managed FortiSwitch features added to FortiOS 5.4.

In FortiOS 5.4.2 and 5.4.1, all FortiGate models (except the FortiGate-80C) support managing FortiSwitches (FortiLink). Note that FortiSwitchOS 3.4.2 or later is required by all of the managed switches. See the FortiOS Feature/Platform matrix for more details and up-to-date compatibility info.

In FortiOS 5.4.0, the following FortiGate models support managed FortiSwitch:

FGT-60D, FGT-60D-POE, FWF-60D, FWF-60D-POE,
FGT-90D, FGT-90D-POE, FWF-90D, FWF-90D-POE,
FGT-100D, FGT-140D, FGT-140D_POE, FGT-140D_POE_T1,
FGT-200D, FGT-240D, FGT-280D, FGT-280D_POE,
FGT-600C, FGT-800C, FGT-1000C,
FGT-1200D, FGT-1500D, FGT-3700D

FortiLink is enabled by default on all physical FortiGate models. FortiLink is disabled by default on all of the FortiGate VMs.

FortiLink interface mode available for on all FortiGate models (309382)(279014)

In FortiOS 5.4.1, all FortiGate models (except the FortiGate-80C) support managing FortiSwitches (FortiLink). Note that FortiSwitchOS 3.4.2 or later is required by all of the managed switches. See the FortiOS Feature/Platform matrix for more details and up-to-date compatibility info.

FortiSwitch interface mode (305212) (279014) (294607)

With prior releases, the FortiGate required a separate FortiLink for each managed FortiSwitch. Starting in FortiOS 5.4.1, the FortiGate requires only one active FortiLink to manage all of the subtending FortiSwitches. The FortiSwitches are inter-connected and operate as one Layer 2 stack.

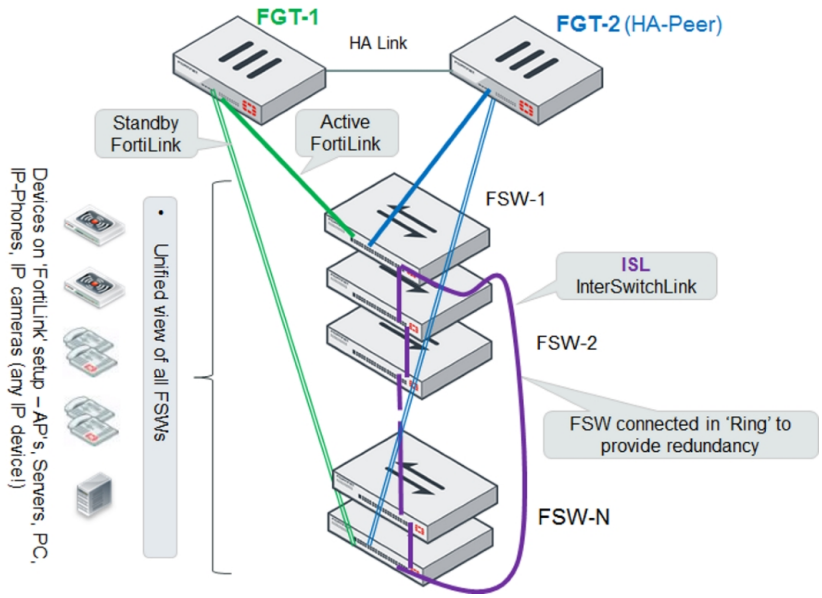
Depending on the network topology, you can also configure a standby FortiLink.

On the FortiGate, you configure the FortiLink as a single port or as a logical interface with multiple ports. The logical interface types supported include link-aggregation group (LAG), hardware switch and software switch.

FortiSwitch stacking (305212) (310481)

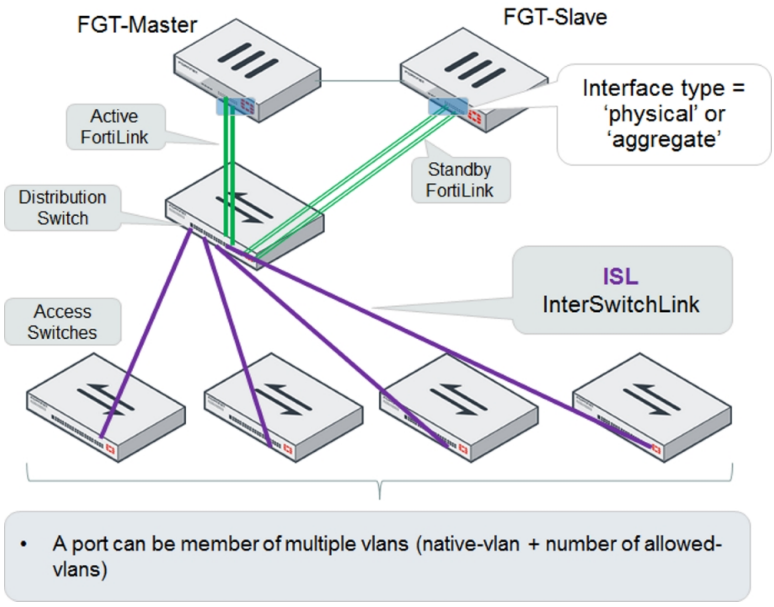
You can connect the managed FortiSwitches in a single-tier topology (aka Stack), or in a hierarchical topology.

In a single-tier topology, you connect a FortiLink from the FortiGate to one switch, and connect the switches in a ring using inter-switch links. Optionally, you can connect a standby FortiLink from the FortiGate to one of the other switches. This FortiLink remains in standby mode unless the active link fails. The following figure shows a single-tier topology with FortiGate HA:



In a hierarchical topology, the FortiSwitches are connected in two tiers, and operate as one Layer 2 cluster. You connect a FortiLink from the top-tier switch to the FortiGate, and the FortiGate then manages each switch separately.

Both topologies support FortiGate HA mode. The following figure shows a hierarchical topology with FortiGate HA:



Execute FortiSwitch commands from a FortiGate (300505)

From the FortiGate, you can execute FortiSwitch commands on the managed FortiSwitch.

This feature adds a simple scripting mechanism for users to configure generic commands to be executed on the switch.

Create a command

Use the following syntax to create a command file:

```
config switch-controller custom-command
   edit <cmd-name>
      set command " <FortiSwitch commands>"
```

The following example creates a command file to set the STP max-age parameter:

```
config switch-controller custom-command
   edit "stp-age-10"
      set command "config switch stp setting
         set max-age 10
         end
      "
   next
end
```

Execute a command

After you have created a command file, use the following command on the FortiGate to execute the command file on the target switch:

```
exec switch-controller custom-command <cmd-name> <target-switch>
```

The following example runs command **stp-age-10** on the specified target FortiSwitch:

```
FGT30E3U15003273 # exec switch-controller custom-command stp-age-10 S124DP3X15000118
```

Allow all defined VLANs in a FortiSwitch configuration (303818)

New port configuration option enables all defined vlans to be allowed on this port. The default value is disabled. This is a conveniece feature, to avoid having to configure all VLANs explicitly in the **allowed-vlans** field.

The following example shows the CLI commands to enable all VLANs on port1 of a managed switch:

```
FG080D3914002825 (managed-switch) # edit S124DN3W14000009
FG080D3914002825 (S124DN3W14000009) # config ports
FG080D3914002825 (ports) # edit port1
FG080D3914002825 (port1) # set allowed-vlans-all enable
```

When **allowed-vlans-all** is enabled, the **allowed-vlans** attribute is hidden.

FortiSwitch logs can be configured to be FortiOS system event logs (286258)

You can enable/disable the managed FortiSwitches to export their syslogs to the FortiGate. The setting is global, and the default setting is disabled.

The FortiGate sets the user field to "fortiswitch-syslog" for each entry, to allow a level of filtering.

CLI Command Syntax

```
config switch-controller switch-log
   status (enable | disable)
   severity [ emergency | alert | critical | error | warning | notification | information
       | debug ]
end
```

Stage or schedule FortiSwitch firmware upgrades (290916)

CLI Changes:

```
Stage FortiSwitch image to a managed FortiSwitch device.

execute switch-controller stage-swtp-image <vdom> <fortiswitch-id> <filename>
```

Example:

```
execute switch-controller stage-swtp-image root S124DN3W14000009 S124DN-IMG.swtp
S124DN3W14000009 # get system status
Version: FortiSwitch-124D v3.4.0,build0156,150929 (Interim)
S124DN3W14000009 # execute reboot
```

Display FortiSwitch port statistics in the FortiGate (303833)

Using the FortiGate CLI, display FortiSwitch port statistics.

Enter the following command. If you omit the port parameter, the FortiGate displays statistics for all of the ports:

```
diagnose switch-controller dump port-stats <switch id> <port>
```

The following example displays FortiSwitch port statistics for port1:

```
diagnose switch-controller dump port-stats S124DN3W14000095 port1
S124DN3W14000095 : Port1
tx-bytes 0, tx-packets 0, tx-mcast 0, tx-errors 0, tx-drops 0, tx-egoodpkts 0, rx-bytes 0,
    rx-packets 0,
rx-mcast 0, rx-errors 0, rx-drops 0, rx-emcasts 0, rx-ebroadcasts 0, rx-eundersize 0, rx-
    efragments 0, rx-eoversize 0, rx-ejabbers 0
rx-ecollisions 0, rx-ecrcalignments 0, rx-egoodpkts 0, rx-l3packets 0,
```

FortiLink per switch port connected device visibility (356560)(0357579) (302087) (303835) (357579)

In the FGT GUI, **User & Device** > **Device LIst** displays a list of devices attached to the FortiSwitch ports. For each device, table displays the IP address of the device, and the interface (FSW name and port).

From the CLI, the following command displays information about the host devices:

```
diagnose switch-controller dump mac-hosts_switch-ports
```

For each device, the CLI displays the IP address of the device, and the interface (FSW name and port).

Display FortiSwitches in Cooperative Security Fabric (CSF) Physical Topology (366873)

Each managed FortiSwitch is displayed as a device subtending the FortiGate.

Log message written when a FortiSwitch connects or disconnects (366519)

Add switch id to the log that is generated when a FortiSwitch connects to the FortiGate, or disconnects.

```
FS1D483Z14000057 is connected
FS1D483Z14000057 is disconnected
```

FortiGate CLI support for FortiSwitch features (on non-FortiLink ports)

You can configure additional FortiSwitch capabilities (STP, LAG, Storm Control) directly from the FortiGate, without the need to log in to the FortiSwitch.

Configuring STP

Starting in FortiSwitch release 3.4.2, STP is enabled by default for the non-FortiLink ports on the switch.

You can enable or disable STP globally, or per-switch-port.

Use the following CLI commands for global configuration:

```
config switch-controller stp-settings
   set status enable/disable
   set name <name>
   set revision <stp revision>
   set hello-time <hello time>
   set forward-time <forwarding delay>
   set max-age <maximum aging time>
   set max-hops <maximum number of hops>
end
```

Use the following commands for global configuration:

```
config switch-controller managed-switch
   edit <switch-id>
      config ports
         edit <port name>
         set stp-state (enabled | disabled)
end
```

Configuring LAG

You can configure a link aggregation group for non-fortilink ports on a FortiSwitch. You cannot configure ports from different FortiSwitches in one LAG.

```
config switch-controller managed-switch
   edit <switch-id>
      config ports
         edit <trunk name>
            set type trunk
            set mode < static | lacp > Link Aggreation mode
            set bundle (enable | disable)
            set min-bundle <int>
            set max-bundle <int>
            set members < port1 port2 ...>
```

```
        next
      end
    end
end
```

Configuring Storm Control

Storm control prevents traffic on a LAN from being disrupted by a broadcast, multicast, or unicast storm on a port. Storm control uses the data rate of the link to measure traffic activity.

When the data rate exceeds the configured threshold, storm control drops excess traffic. You can configure the types of traffic to drop: broadcast, unknown unicast, or multicast.

The Storm Control settings are global to all of the non-FortiLink ports on the managed switches. Use the following CLI commands to configure storm control:

```
config switch-controller switch-storm-control
   set rate <rate>
   set unknown-unicast (enable | disable)
   set unknown-multicast (enable | disable)
   set broadcast (enable | disable)
end
```

The Rate units is packets per second. The default value is 500.

New FortiLink topology diagram (289005 271675 277441)

For managed FortiSwitches (**WIFI & Switch Controller > Managed FortiSwitch**), the system now displays the overall topology of the managed FortiSwitches that are connected to this FortiGate.

The topology lists the FortiLink ports on the FortiGate, and displays a full faceplate for each connected FortiSwitch (also showing the FortiLink ports on each FortiSwitch). You can right-click to authorize a managed FortiSwitch or left-click to edit the managed FortiSwitch information.

The topology can displays multiple FortiLinks to each FortiSwitch, as FortiOS 5.4 provides support for FortiLink as a LAG.

New interface option to auto-authorize extension devices 294966

If you enable the auto-authorize option on a FortiGate FortiLink port, the FortiGate will automatically authorize the managed FortiSwitch connected to this FortiLink. The new option is only visible when the interface type is set to **Dedicate to Extension Device**.

New CLI setting to enable pre-standard PoE detection on managed FortiSwitch ports 293512

This feature is available in FortiSwitchOS 3.3.2 and later releases.

Use the following commands to enable this setting on a managed FortiSwitch port:

```
config switch-controller managed-switch
   edit $FSW
      config ports
         edit "port1"
         set poe-pre-standard-detection enable/disable (the default is disable)
         next
```

```
        end
    end
```

Reset any POE port (by toggling the power OFF and then ON):

```
execute switch-controller poe-reset <fortiswitch-id> <port>
```

Display general POE status:

```
get switch-controller <fortiswitch-id> <port>
```

FortiGate HA cluster support for Managed Switches (276488)

Added the capability to support managed switches from a FortiGate HA cluster. If a standby FortiGate becomes active, it automatically establishes connectivity with the managed switches.

FortiLink GUI updates (288963)

New **VLAN** view to create and manage VLANs, including setting the VLAN id.

New **Ports** view of the managed FortiSwitches. The view now displays port status, including the assigned VLAN and the POE status for each port.

This view provides a clearer way to assign VLAN attributes to multiple ports on different FortiSwitches. The VLAN ID and color of each VLAN is clearly visible in the port assignment list. Also, when you configure a VLAN, you can now specify the VLAN ID.

Changing the FortiGate's inspection mode to flow or proxy

You can select Flow or Proxy Inspection Mode from the System Information dashboard widget to control your FortiGate's security profile inspection mode. Having control over flow and proxy mode is helpful if you want to be sure that only flow inspection mode is used (and that proxy inspection mode is not used).

Switching to Flow Inspection Mode also turns off WAN Optimization, Web Caching, the Explicit Web Proxy, and the Explicit FTP Proxy making sure that no proxying can occur.

In most cases proxy mode is preferred because more security profile features are available and more configuration options for these individual features are available. Some implementations; however, may require all security profile scanning to only use flow mode. In this case, you can set your FortiGate to flow mode knowing that proxy mode inspection will not be used.

If you select flow-based to use external servers for FortiWeb and FortiMail you must use the CLI to set a Web Application Firewall profile or Anti-Spam profile to external mode and add the Web Application Firewall profile or Anti-Spam profile to a firewall policy.

Changing between proxy and flow mode

Proxy mode is enabled by default and you change to flow mode by changing the **Inspection Mode** on the System Information dashboard widget.

When you select **Flow-based** you are reminded that all proxy mode profiles are converted to flow mode, removing any proxy settings. As well proxy-mode only features (for example, Web Application Profile) are removed from the GUI.

In addition, selecting **Flow-based** inspection will cause the **Explicit Web Proxy** and **Explicit FTP Proxy** features to be removed from the GUI and the CLI. This includes Explicit Proxy firewall policies.

When you select **Flow-based** you can only configure Virtual Servers (under **Policy & Objects > Virtual Servers**) with Type set to HTTP, TCP, UDP, or IP.

If required, you can change back to proxy mode through the System Information dashboard widget.

If your FortiGate has multiple VDOMs, you can set the inspection mode independently for each VDOM. Use the top left dropdown menu to go to **Global > System > VDOM**. Click **Edit** for the VDOM you wish to change and select the **Inspection Mode**.

Security profile features mapped to inspection mode

The table below lists FortiOS security profile features and shows whether they are available in flow-based or proxy-based inspection modes.

The DNS Filter security profile feature is only available for proxy-based inspection in FortiOS versions 5.4.0 and 5.4.1. It is available for both proxy-based and flow-based inspection in FortiOS versions 5.4.2 and above.

Security Profile Feature	Flow-based inspection	Proxy-based inspection
AntiVirus	x	x
Web Filter	x	x
DNS Filter	x	x
Application Control	x	x
Cloud Access Security Inspection	x	x
Intrusion Protection	x	x
Anti-Spam		x
Data Leak Protection		x
VoIP		x
ICAP		x
Web Application Firewall		x

Security Profile Feature	Flow-based inspection	Proxy-based inspection
FortiClient Profiles	x	x
Proxy Options		x
SSL/SSH Inspection	x	x
Web Rating Overrides	x	x
Web Profile Overrides		x

From the GUI, you can only configure antivirus and web filter security profiles in proxy mode. From the CLI you can configure flow-based antivirus profiles, web filter profiles and DLP profiles and they will appear on the GUI and include their inspection mode setting. Also, flow-based profiles created when in flow mode are still available when you switch to proxy mode.

In flow mode, antivirus and web filter profiles only include flow-mode features. Web filtering and virus scanning is still done with the same engines and to the same accuracy, but some inspection options are limited or not available in flow mode. Application control, intrusion protection, and FortiClient profiles are not affected when switching between flow and proxy mode.

CASI does not work when using proxy-based profiles for AV or Web filtering. Make sure to only use flow-based profiles in combination with CASI on a specific policy.

Even though VoIP profiles are not available from the GUI in flow mode, the FortiGate can process VoIP traffic. In this case the appropriate session helper is used (for example, the SIP session helper).

Setting flow or proxy mode doesn't change the settings available from the CLI. However, when in flow mode you can't save security profiles that are set to proxy mode.

You can also add proxy-only security profiles to firewall policies from the CLI. So, for example, you can add a VoIP profile to a security policy that accepts VoIP traffic. This practice isn't recommended because the setting will not be visible from the GUI.

Proxy mode and flow mode antivirus and web filter profile options

The following tables list the antivirus and web filter profile options available in proxy and flow modes.

Antivirus features in proxy and flow mode

Feature	Proxy	Flow
Scan Mode (Quick or Full)	no	yes
Detect viruses (Block or Monitor)	yes	yes
Inspected protocols	yes	no (all relevant protocols are inspected)

Feature	Proxy	Flow
Inspection Options	yes	yes (not available for quick scan mode)
Treat Windows Executables in Email Attachments as Viruses	yes	yes
Send Files to FortiSandbox Appliance for Inspection	yes	yes
Use FortiSandbox Database	yes	yes
Include Mobile Malware Protection	yes	yes

Web Filter features in proxy and flow mode

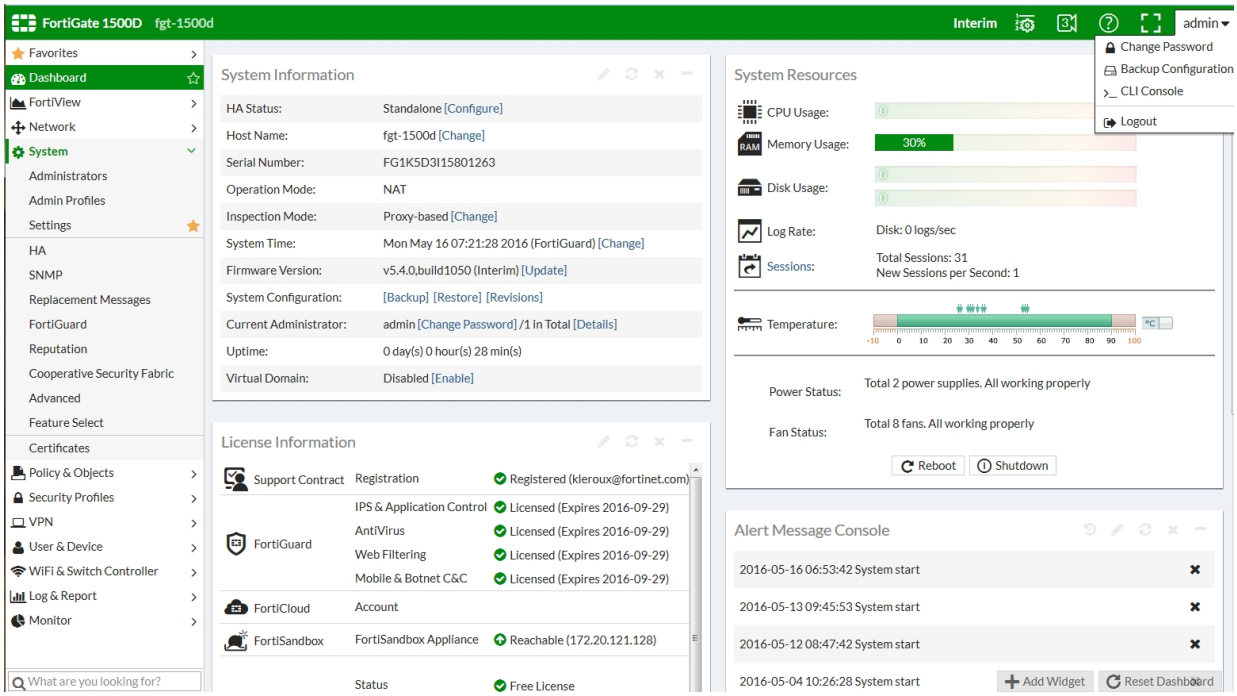
Feature		Proxy	Flow
FortiGuard category based filter		yes	yes (show, allow, monitor, block)
Category Usage Quota		yes	no
Allow users to override blocked categories (on some models)		yes	no
Search Engines		yes	no
	Enforce 'Safe Search' on Google, Yahoo!, Bing, Yandex	yes	no
	Restrict YouTube Access	yes	no
	Log all search keywords	yes	no
Static URL Filter		yes	yes
	Block invalid URLs	yes	no
	URL Filter	yes	yes
	Block malicious URLs discovered by FortiSandbox	yes	yes
	Web Content Filter	yes	yes
Rating Options		yes	yes

Feature		Proxy	Flow
	Allow websites when a rating error occurs	yes	yes
	Rate URLs by domain and IP Address	yes	yes
	Block HTTP redirects by rating	yes	no
	Rate images by URL	yes	no
Proxy Options		yes	no
	Restrict Google account usage to specific domains	yes	no
	Provide details for blocked HTTP 4xx and 5xx errors	yes	no
	HTTP POST Action	yes	no
	Remove Java Applets	yes	no
	Remove ActiveX	yes	no
	Remove Cookies	yes	no
	Filter Per-User Black/White List	yes	no

GUI Refresh

The FortiGate GUI now uses a new flat GUI design and framework that incorporates a simplified and modern look and feel. In addition to the new look, options have been moved around on the GUI menus:

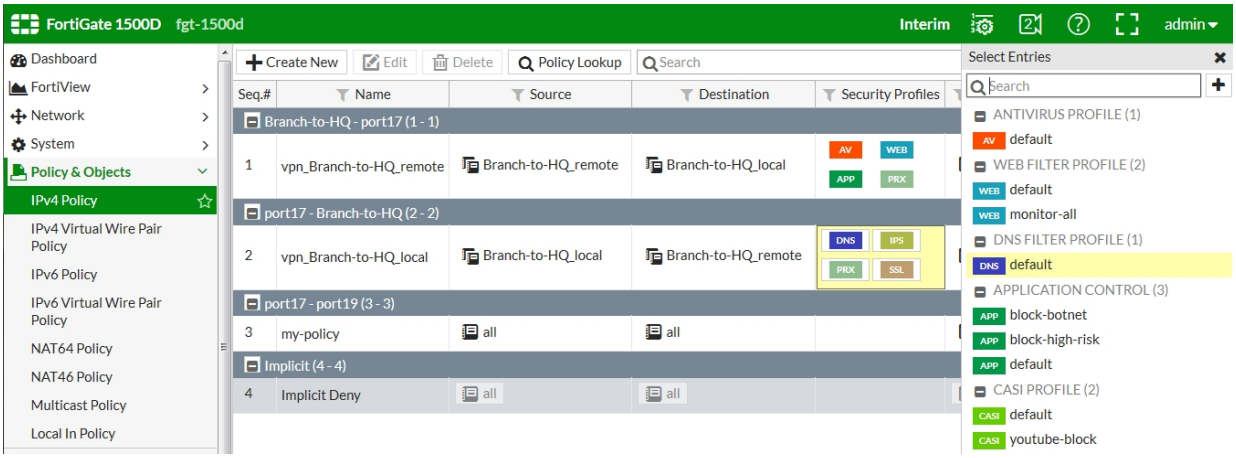
- New **Dashboard** and **FortiView** top level menus.
- New top level **Network** menu includes networking features such as interfaces, DNS, explicit proxy, packet capture, WAN links (WAN load balancing), static routing, policy routing, dynamic routing (RIP, OSPF, BGP) and multicast routing.
- New top level **Monitor** menu collects monitoring functions previously distributed throughout the GUI. Some former monitoring features, such as security profile-related monitoring, are now available in FortiView.
- The GUI menu now has two levels only. For example the menu path for accessing IPv4 firewall policies is **Policy & Objects > IPv4**.
- The new administrator's menu (upper right) provides quick access to change the administrator's password , backup the FortiGate configuration, access the CLI console and log out.
- Most individual GUI pages have also been enhanced with new view options and more information.
- Some functionality has moved around in the GUI. For example, **Proxy Options** and **SSL/SSH Inspection** moved from **Policy & Objects** to **Security Profiles**.



New options for editing policies from the policy list

All of the security policy lists (**Policy & Objects > IPv4** and so on) have new options for controlling the columns displayed for policies, for editing policies, and for accessing FortiView data or log messages generated by individual policies. You can access these options clicking or right-clicking on the policy list header or on individual policies.

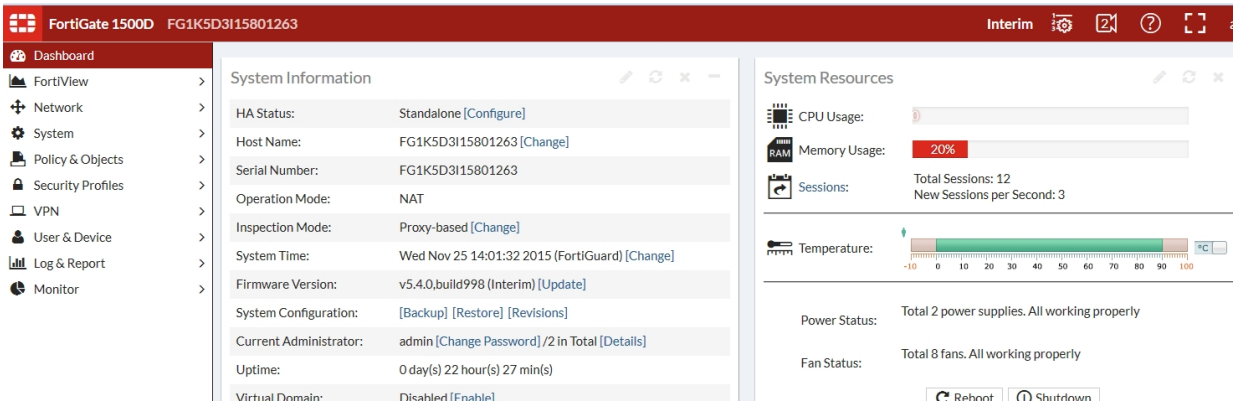
For example, as shown below if you click on the Security Profiles settings for a policy a list of categories and profiles appears on the left of the GUI. The list highlights the security profile options added to the policy. You can select a profile option to add it to a policy. You can deselect an option to remove it from a policy. Similar lists are available to select addresses, services, user groups, devices, and so on.



Changing the GUI theme

You can go to **System > Settings > View Settings** and select a **Theme**. You can also use the following CLI command to change the GUI theme. The following command shows how to change the GUI to use the red theme:

```
config system global
   set gui-theme red
end
```



Full screen mode

You can use the Full Screen Mode button (between the online help button and the admin menu) to toggle full screen mode. In full screen mode the GUI menu and header are hidden the full browser window is taken up by the current GUI page. You can select the Exit Full Screen mode any time to return to the normal GUI arrangement.

Edit in CLI

Available in the following locations among others in the FortiOS GUI you can select the Edit in CLI option to edit an item in the CLI.

- Firewall policy
- Firewall address
- Firewall service
- Firewall schedule
- Traffic shaper
- Shaping policy
- Policy route
- Static route
- Managed FortiAP

For example, if you are looking at a Firewall policy on the GUI and select Edit in CLI, the CLI console opens up inside the CLI configuration of the same policy. Some configurations options are only available from the CLI and this control allows you to easily edit specific items without having to find the item in the CLI.

Display the hostname on the GUI login page (129248)

- You can use the following CLI command to display the hostname on the GUI login page

```
config system global
   set gui-display-hostname {disable | enable}
end
```

Other GUI changes(129248)

- You can no longer add custom dashboard tabs. The following CLI command has been removed:

```
config system admin
   edit <admin>
      config dashboard-tabs
   end
```

- Lite version of the GUI (available on some low level models) has been removed including the following CLI command:

```
config system settings
   set gui-lite (disable | enable}
end
```

- You can no longer configure multiple custom dashboard widgets. The following CLI command has been removed:

```
config system admin
   edit <admin>
      config dashboard
         edit 0
            set widget-type app-usage
            set widget-type storage
            set widget-type protocol-usage
            set widget-type device-os-dist "Device/
         next
```

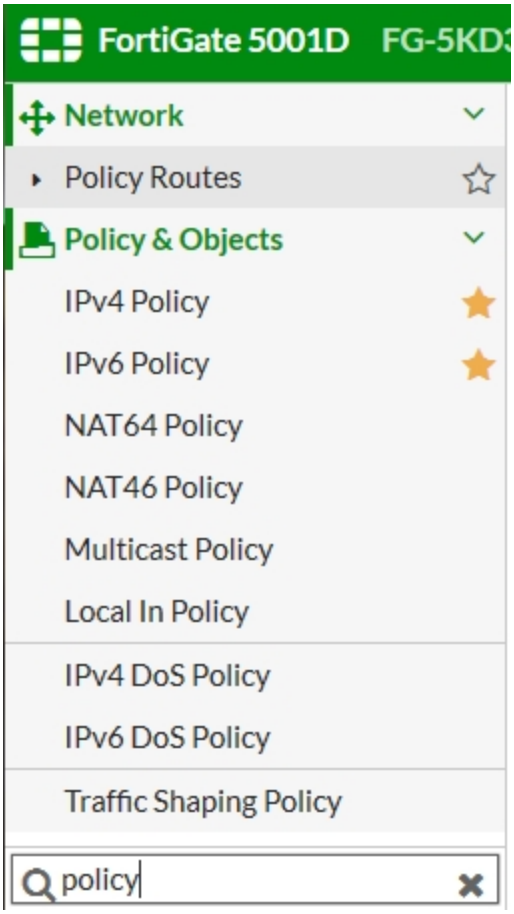
- HTTP obfuscating has also been removed, including the following CLI command.

```
config system global
   set http-obfuscate
end
```

GUI favorite and search (307478)

If there is a GUI page that you use often, rather than having to click through the GUI menu to find it you can select the star icon to make it a favorite page. Making something a favorite adds a new Favourites menu, which, when you open it, lists your favourite GUI pages. The GUI page at the top of the favourites list will be the page that appears the next time you log into the GUI. Favorites are saved for individual administrator accounts. Making a page a favourite doesn't remove it from its location in the GUI menu.

You can use the new search field at the bottom of the GUI menu to search for GUI page names. All of the GUI page names that match your appear and you can select the one you are looking for.



- Most diagnose sys dashboard commands removed (129248)

  The `diagnose sys dashboard reset` command is still available.

DNS Filter

Blocking DNS requests to known Botnet C&C addresses

A new FortiGuard database contains a list of known Botnet C&C addresses. This database is updated dynamically and stored on the FortiGate. This database is covered by FortiGuard web filter licensing, so you must have a FortiGuard web filtering license to use this feature.

When you block DNS requests to known Botnet C&C addresses, using IPS, DNS lookups are checked against the Botnet C&C database. All matching DNS lookups are blocked. Matching uses a reverse prefix match, so all sub-domains are also blocked.

To enable blocking of DNS requests to known Botnet C&C addresses, go to **Security Profiles > DNS Filter**, and enable **Block DNS requests to known botnet C&C**.

Static URL filter

The DNS inspection profile static URL filter allows you to block, exempt, or monitor DNS requests by using IPS to look inside DNS packets and match the domain being looked up with the domains on the static URL filter list. If there is a match the DNS request can be blocked, exempted, monitored, or allowed.

If blocked, the DNS request is blocked and so the user cannot look up the address and connect to the site.

If exempted, access to the site is allowed even if another method is used to block it.

DNS-based web filtering

This feature is similar to the FortiGuard DNS web filtering available in FortiOS 5.2. You can configure DNS web filtering to allow, block, or monitor access to web content according to FortiGuard categories. When DNS web filtering is enabled, your FortiGate must use the FortiGuard DNS service for DNS lookups. DNS lookup requests sent to the FortiGuard DNS service return with an IP address and a domain rating that includes the FortiGuard category of the web page.

If that FortiGuard category is set to block, the result of the DNS lookup is not returned to the requester. If the category is set to redirect, then the address returned to the requester points at a FortiGuard redirect page.

You can also allow access or monitor access based on FortiGuard category.

CLI commands

Rename webfilter-sdns-server-ip and webfilter-sdns-server-port:

```
config system fortiguard
   set sdns-server-ip x.x.x.x
   set sdns-server-port 53
end
```

Configure DNS URL filter:

```
config dnsfilter urlfilter
   edit 1
      set name "url1"
      set comment ''
         config entries
```

```
            edit 1
               set url "www.google.com"
               set type simple
               set action block
               set status enable
            next
            edit 2
               set url "www.yahoo.com"
               set type simple
               set action monitor
               set status enable
            next
            edit 3
               set url "www.foritnet.com"
               set type simple
               set action allow
               set status enable
            next
         end
   next
end
```

Configure DNS filter profile:

```
config dnsfilter profile
   edit "dns_profile1"
      set comment ''
         config urlfilter
            set urlfilter-table 1
         end
         config ftgd-dns
               config filters
                  edit 1
                     set category 49
                     set action block
                     set log enable
                  next
                  edit 2
                     set category 71
                     set action monitor
                     set log enable
                  next
               end
         end
      set log-all-url disable
      set block-action redirect
      set redirect-portal 0.0.0.0
      set block-botnet enable
   next
end
```

Configure DNS profile in a firewall policy:

```
config firewall policy
   edit 1
      set srcintf "any"
      set dstintf "any"
      set srcaddr "all"
```

```
      set dstaddr "all"
      set action accept
      set schedule "always"
      set service "FTP"
      set utm-status enable
      set dnsfilter-profile "dns_profile1"
      set profile-protocol-options "default"
      set nat enable
   next
end
```

Configure DNS profile in profile group:

```
config firewall profile-group
   edit "pgrp1"
      set dnsfilter-profile "dns_profile1"
      set profile-protocol-options "default"
   next
end
```

FortiSandbox Integration

This chapter describes new FortiSandbox features added to FortiOS 5.4.

FortiSandbox Log entry (302818)

Users can correlate submissions to FortiSandbox with the verdict on those files by viewing results at **Log & Report > AntiVirus**.

Changes to FortiSandbox inspection options in AntiVirus profile

When configuring the AntiVirus profile's inspection options, users can withhold files from being submitted for inspection by type or by name pattern.

Changes to FortiSandbox GUI configuration options (354523)

This change allows you to enable the FortiSandbox appliance from the Dashboard's License Information widget.

1. Go to **Dashboard**. Locate the License Information widget and click on the **Configure** button in the FortiSandbox row.
2. You will be directed to the **System > Cooperative Security Fabric** page.

NOTE: Continue with steps 3 to 9 under **Connecting to a FortiSandbox** below.

FortiSandbox Integration with FortiOS

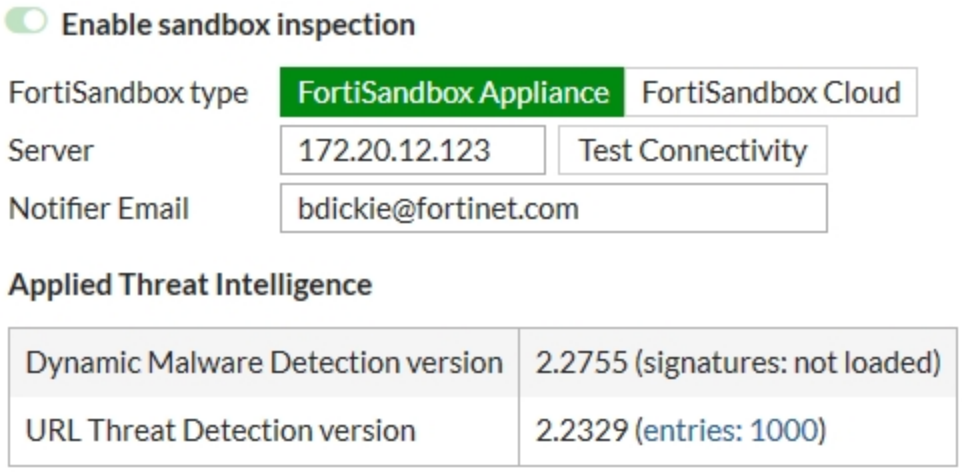
The following improvements have been made to how sandboxing, using either a FortiSandbox Appliance or FortiCloud Sandboxing, integrates with a FortiGate unit.

See the Cookbook recipe Sandboxing with FortiSandbox and FortiClient, http://cookbook.fortinet.com/sandboxing-fortisandbox-forticlient-54/.

Connecting to a FortiSandbox

1. Go to **System > Cooperative Security Fabric** and select **Enable Sandbox Inspection**.
2. You can either select **FortiSandbox Appliance** or **FortiSandbox Cloud**.

3. If you select FortiSandbox Appliance, add the **Server** IP address.

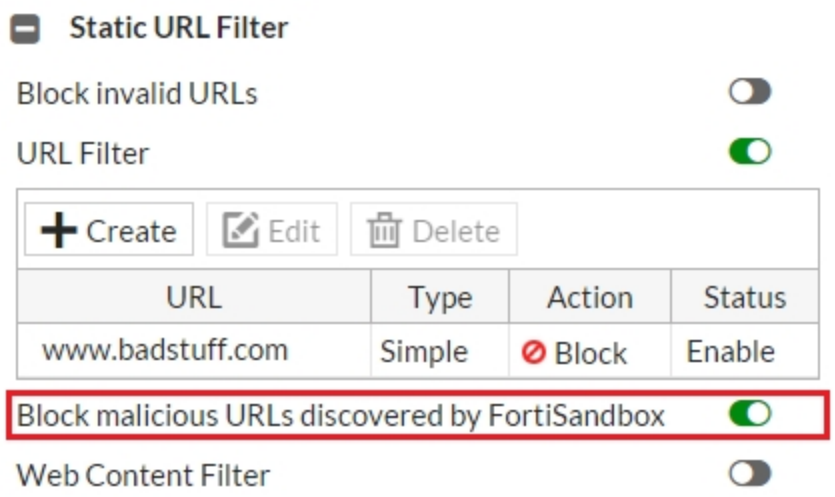


4. Select **Test Connectivity** to verify that you can connect to FortiSandbox.
5. Then edit an AntiVirus profile by going to **Security Profiles > AntiVirus** and selecting **Send Filter to FortiSandbox Appliance for Inspection**.
6. In FortiOS 5.4.0, you can also elect to send Suspicious Files, Executable files or all supported files.
   In FortiOS 5.4.1, you can choose to **Treat Windows Executables in Email Attachments as Viruses** and **Send All Supported Files**. When you select **Send All Supported Files**, you then have the option of withholding files from FortiSandbox inspection by type or by name pattern.
7. Select **Use FortiSandbox Database** to add signatures for suspicious files found by FortiSandbox to your FortiGate antivirus signature database.
8. Then add this AntiVirus profile to a firewall policy to send files in traffic accepted by the firewall policy to FortiSandbox.
9. You can also go to **Security Profiles > Web Filter** and select **Block malicious URLs discovered by FortiSandbox**.

Pushing malicious URLs to Web Filtering

The malicious URL database contains all malicious URLs active in the last month. The FortiSandbox can add the URLs where any malicious files originated to a URL filter, to block these files from being downloaded again from that URL.

This feature is enabled in a Web Filter profile under **Security Profiles > Web Filter > Block malicious URLs discovered by FortiSandbox**.



CLI Syntax

```
config webfilter profile
   edit <profile>
      config web
         ...
         set blacklist [enable | disable]
         ...
      end
```

Files blocked by a FortiSandbox signature can be viewed and filtered for in the FortiSandbox dashboard. Information on the current database for both malware signatures and blocked URLs can be found by going to **System > Cooperative Security Fabric**.

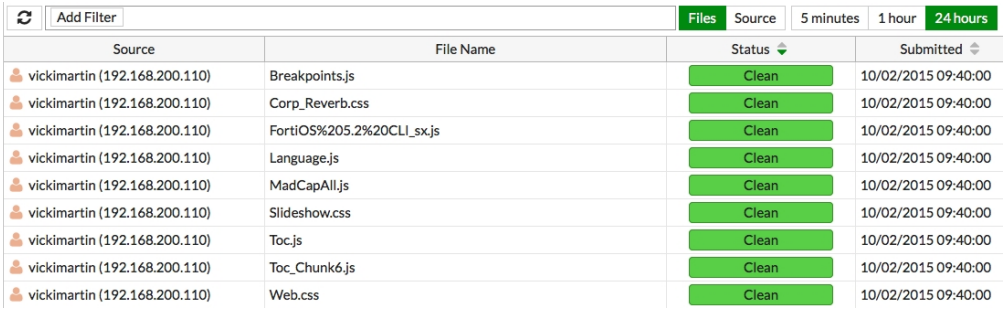
FortiSandbox statistics (last 7 days)

File type	Detected
Total submitted	0
Malicious	0
Suspicious (high risk)	0
Suspicious (medium risk)	0
Suspicious (low risk)	0
Clean	0

FortiSandbox Dashboard in FortiView

The FortiSandbox dashboard is available from **FortiView > FortiSandbox**. The dashboard shows all samples submitted for sandboxing. Information on the dashboard can be filtered by checksum, file name, result, source,

status, and user name. Each entry also offers a drilldown view to show more details about a particular sample.



Source	File Name	Status	Submitted
vickimartin (192.168.200.110)	Breakpoints.js	Clean	10/02/2015 09:40:00
vickimartin (192.168.200.110)	Corp_Reverb.css	Clean	10/02/2015 09:40:00
vickimartin (192.168.200.110)	FortiOS%205.2%20CLI_sx.js	Clean	10/02/2015 09:40:00
vickimartin (192.168.200.110)	Language.js	Clean	10/02/2015 09:40:00

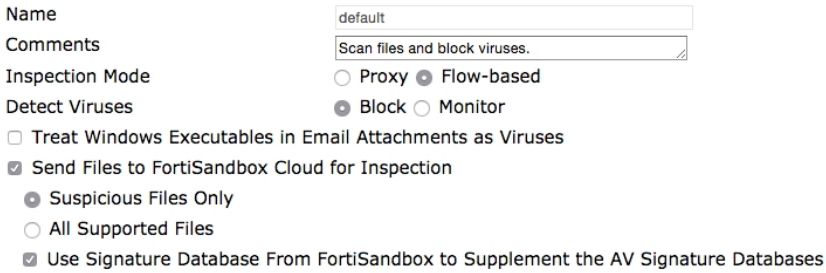
vickimartin (192.168.200.110)	Toc_Chunk6.js	Clean	10/02/2015 09:40:00
vickimartin (192.168.200.110)	Web.css	Clean	10/02/2015 09:40:00

Pushing signatures to AntiVirus database

When a FortiSandbox discovers a malicious file, it can create a signature that is sent to the FortiGate to supplement the AntiVirus signature database. This signature can be used to block that file from entering the network again, and to prevent duplicates of the file being sent to the FortiSandbox in the future. This feature is enabled in an AntiVirus profile.



CLI Syntax

```
config antivirus profile
   edit "default"
      set ftgd-analytics {everything | suspicious}
      set analytics-db {enable | disable}
   end
```

Files blocked by a FortiSandbox signature can be viewed in entirety or as a filtered list in the FortiSandbox dashboard.

Information on the current database for malware signatures and blocked URLs can be found by going to **System > Cooperative Security Fabric**.

FortiSandbox statistics (last 7 days)

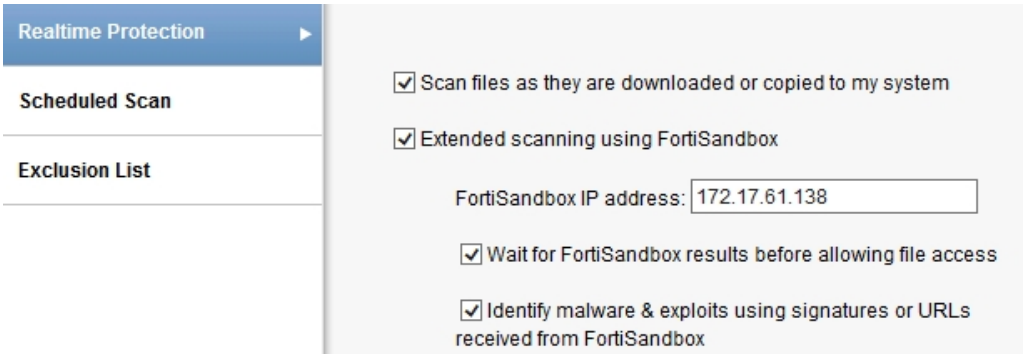
File type	Detected
Total submitted	0
Malicious	0
Suspicious (high risk)	0
Suspicious (medium risk)	0
Suspicious (low risk)	0
Clean	0

FortiClient Monitoring and Quarantine

FortiClient monitoring and quarantine is currently only supported by FortiClient 5.4 for Windows.

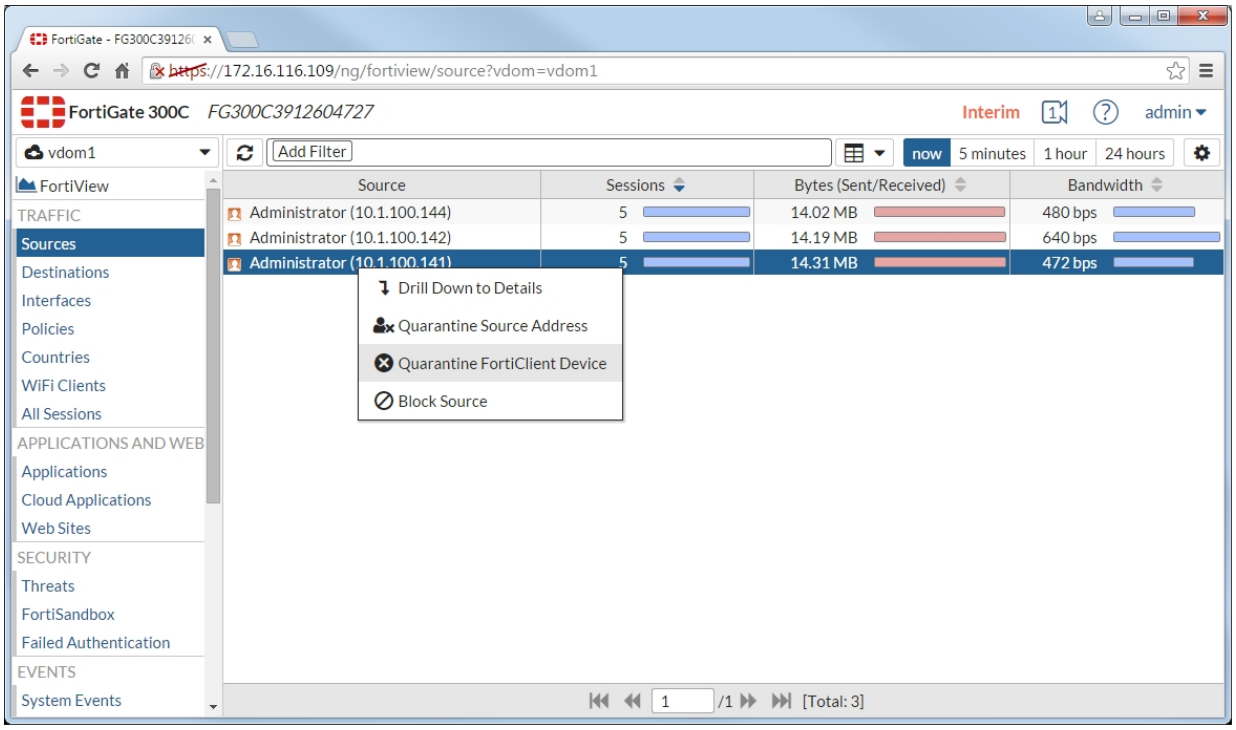
FortiSandbox uses a single signature to identify tens of thousands of variations of viral code. A FortiSandbox can send frequent, dynamic signature updates to a FortiGate and FortiClient, which allows files to be blocked before they are sent to the FortiSandbox.

With FortiSandbox, FortiClient, and FortiGate integration, you can configure a FortiGate to send files to FortiSandbox for scanning.

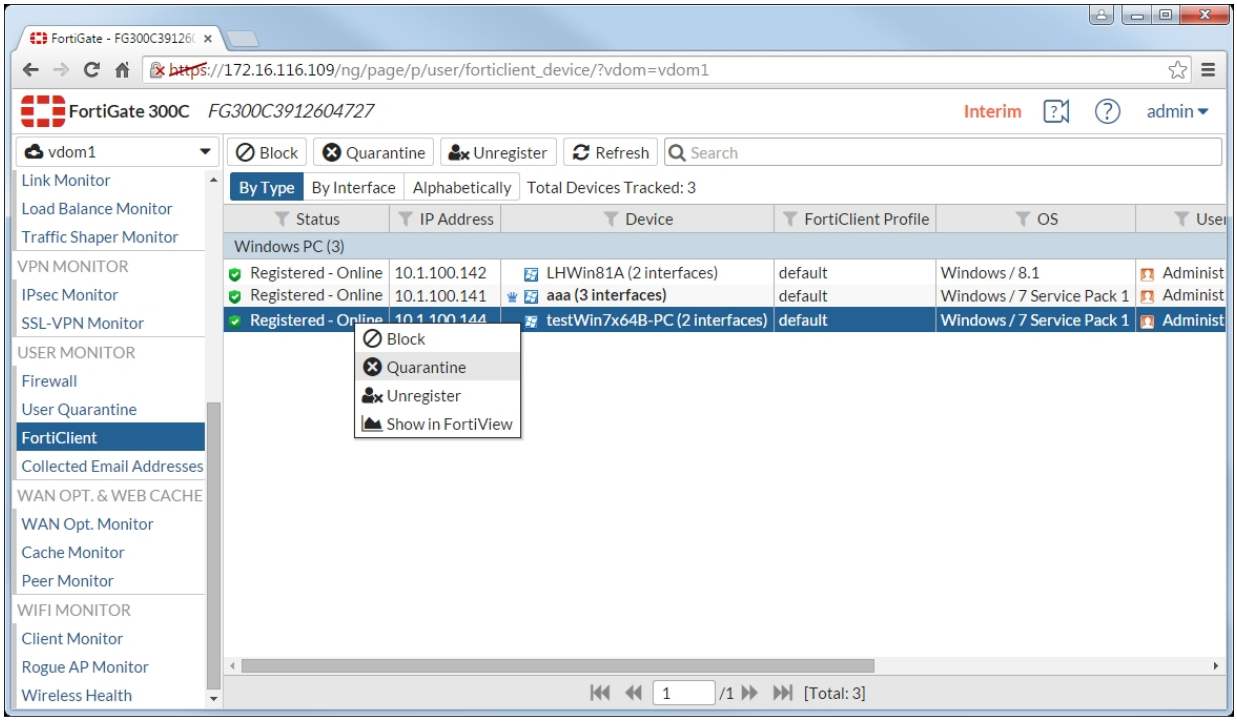


When FortiSandbox determines that a file is infected, it will notify the FortiGate of this event. Then, from FortiView, the administrator can take action to quarantine the endpoint which downloaded the infected file.

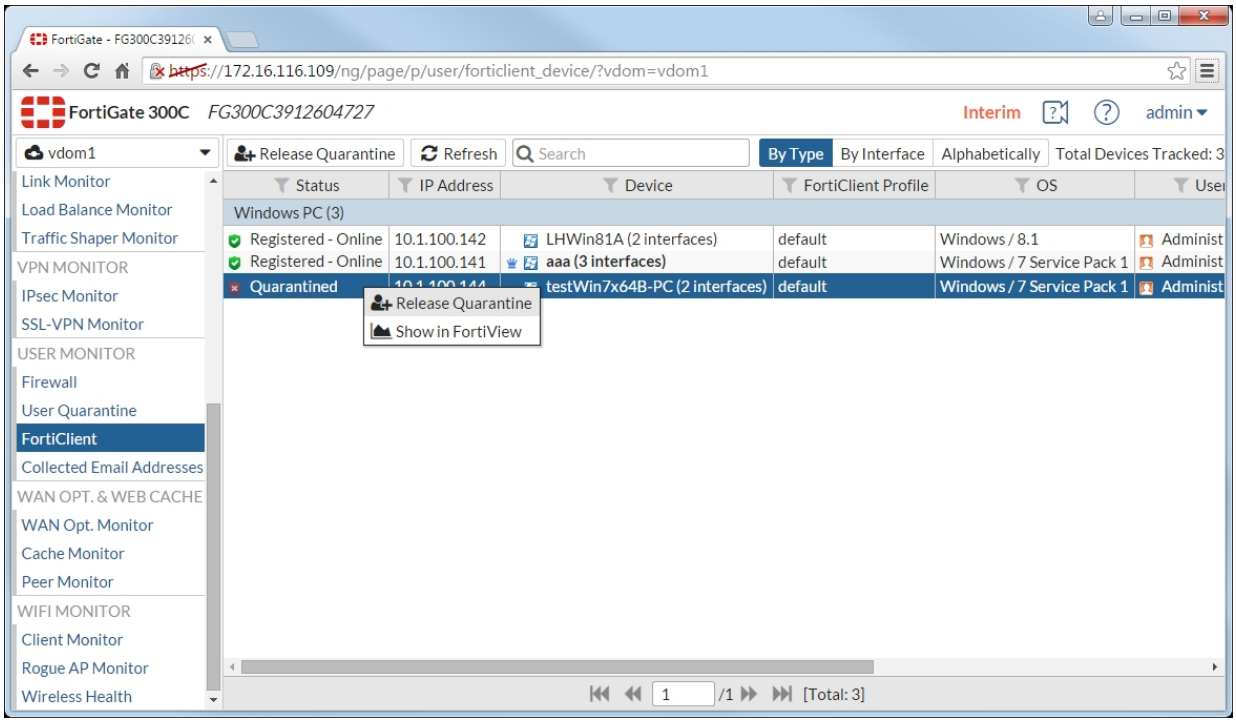
FortiGate administrators can quarantine endpoints from FortiView.



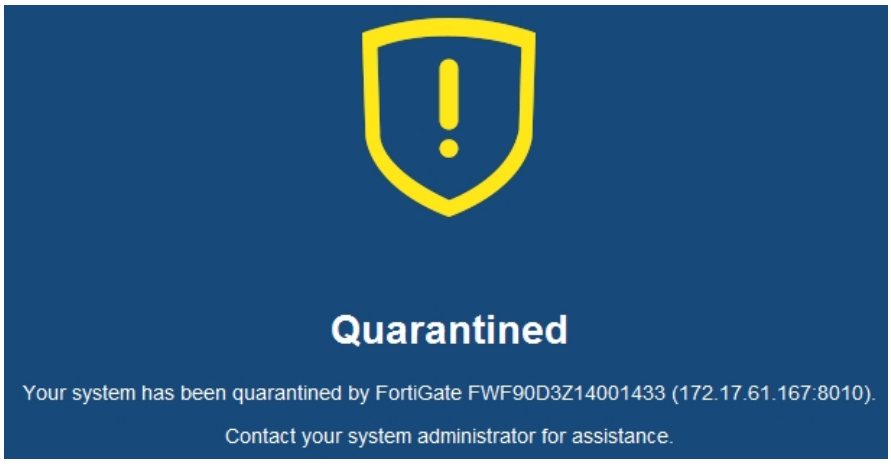
FortiGate administrators can also quarantine endpoints from the FortiClient Monitor.



FortiGate administrators can also manually release a quarantined endpoint.



To support this, the FortiClient now supports host-level quarantine by cuting off other network traffic from the endpoint directly and preventing it from infecting or scanning the local network.



When a device is under quarantine, FortiClient cannot be shutdown or uninstalled. A user is also unable to unregister from the FortiGate that quarantined them, or register to another FortiGate unit.

Alternately, FortiGate can release the file to the client before receiving the FortiSandbox scan results, and then have FortiClient quarantine the device when the scan results are available if required.

Traffic Shaping Policies

This chapter describes new traffic shaping features added to FortiOS 5.4.

Traffic shaping policy IDs added to traffic logs (303802)

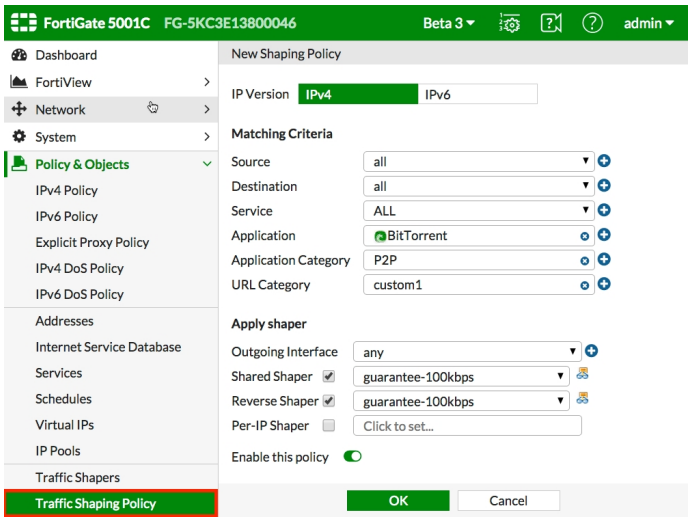
As of build 1013, traffic shaping policy IDs are now displayed in traffic logs and IP sessions. This allows you to easily identify which shaping policy is applied to traffic, even with multiple shaping policies configured. Look at the example below to see a sample log with the `shapingpolicyid`:

```
date=2016-01-29 time=15:35:25 logid=0000000013 type=traffic subtype=forward
level=notice vd=vdom1 srcip=192.0.2.2 srcname="A" srcport=43041
srcintf="port3" dstip=203.0.113.55 dstport=80 dstintf="port11"
poluuid=bcd3b008-c6bd-51e5-0e2c-2002e7a5774d sessionid=18364 proto=6
action=close policyid=2 policytype=policy dstcountry="Reserved"
srccountry="Reserved" trandisp=snat transip=192.0.2.2 transport=43041
service="HTTP" duration=205 sentbyte=747285 rcvdbyte=26382426 sentpkt=12887
rcvdpkt=17592 shapingpolicyid=1 shapersentname="shaper400"
shaperdropsentbyte=0 shaperrcvdname="shaper200" shaperdroprcvdbyte=14065762
appcat="unscanned" devtype="Fortinet Device" osname="Fortinet OS"
mastersrcmac=33:5b:0e:ca:dd:dc srcmac=33:5b:0e:ca:dd:dc
```

New Traffic Shaper Policy Configuration Method (269943)

Previously, traffic shapers were configured in **Policy & Objects > Objects > Traffic Shapers** and then applied in security policies under **Policy & Objects > Policy > IPv4** . In FortiOS 5.4, traffic shapers are now configured in a new traffic shaping section in **Policy & Objects > Traffic Shapers**.

The way that traffic shapers are applied to policies has changed significantly in 5.4., because there is now a specific section for traffic shaping policies in **Policy & Objects > Traffic Shaping Policy**. In the new traffic shaping policies, you must ensure that the **Matching Criteria** is the **same** as the security policy or policies you want to apply shaping to. The screen shot below shows the new 5.4 GUI interface:



There is also added Traffic Shaper support based on the following:

- Source (Address, Local Users, Groups)
- Destination (Address, FQDN, URL or category)
- Service (General, Web Access, File Access, Email and Network services, Authentication, Remote Access, Tunneling, VoIP, Messaging and other Applications, Web Proxy)
- Application
- Application Category
- URL Category

Creating Application Control Shapers

Application Control Shapers were previously configured in the **Security Profiles > Application Control** section, but for simplicity they are now consolidated in the same section as the other two types of traffic shapers: Shared and Per-IP.

To create an Application Control Shaper, you must first enable application control at the policy level, in **Policy & Objects > Policy > [IPv4 or IPv6]**. Then, you can create a matching application-based traffic shaping policy that will apply to it, in the new Traffic Shaping section under **Policy & Objects > Traffic Shaping Policy**.

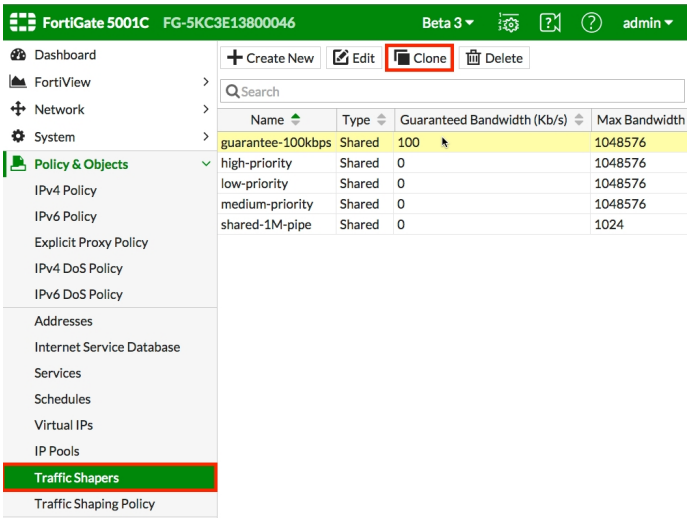
New attributes added to "firewall shaping-policy" (277030) (275431)

The two new attributes are `status` and `url-category`. The `status` attribute verifies whether the policy is set to enabled or disabled. The `url-category` attribute applies the shaping-policy to sessions without a URL rating when set to 0, and no web filtering is applied.

```
Syntax:
config firewall shaping-policy
   edit 1
      set status enable
      set url-category [category ID number]
```

New button added to "Clone" Shapers

You can now easily create a copy of an existing shaper by selecting the shaper and clicking the **Clone** button.



WAN link load balancing

In the same way that incoming traffic can be load balanced, outgoing or WAN traffic can also be load balanced and for the same three reasons.

1. Reduce the places in the work flow where a single point of failure can bring the process to a halt.
2. Expand the capacity of the resources to handle the required workload.
3. Have it configured so that the process of balancing the workload is automatic.

Often, it can be just as important for an organizations members to be able to access the Internet as it is for the denizens of the Internet to access the Web facing resources.

There is now a **WAN Load Balancing** feature located in the **Network** section of the GUI ("WAN LLB").

As part of the new WAN Load Balancing feature, the FortiOS 5.2 **Router > Static > Settings** GUI page has been removed. WAN Load Balancing should be used instead of the 5.2 **ECMP Load Balancing Method** settings. The 5.2 **Link Health Monitor** definitions are now only available from the CLI.

WAN links

The basis for the configuration of the virtual WAN link are the interfaces that comprise it. As interfaces are added to the "wan-load-balance" interface, they are added into the calculations that comprise the various algorithms used to do the load balancing.

- While most of the load balancing algorithms are based on equal distribution or weighted distribution, spill over does rely on which interface is first in the sequence, so this should be kept in mind when adding the interfaces.
- The interfaces in the virtual WAN link can be disabled if necessary if work needs to be done on an interface without interfering with the performance of the link.
- There is no requirement that the interfaces be those labeled on the hardware as WAN interfaces.
- In the GUI, to help analysis the effectiveness of the algorithm being used and its configuration, there is a graphic representation of the bandwidth usage of the link.

Load balancing algorithm

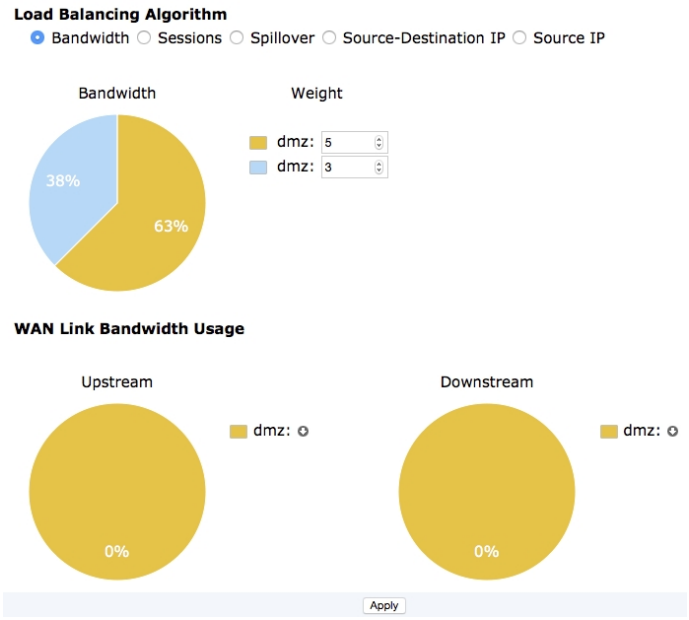
Once the interfaces involved has been configured the next step is to determine how the workload will be distributed. 5 load balancing algorithms are available to choose from.

Bandwidth

This is a very straight forward method of distributing the work load based on the amount of packets going through the interfaces. An integer value assigns a weight to each interface. These weights are used to calculate a percentage of the total bandwidth that is directed to the interface.

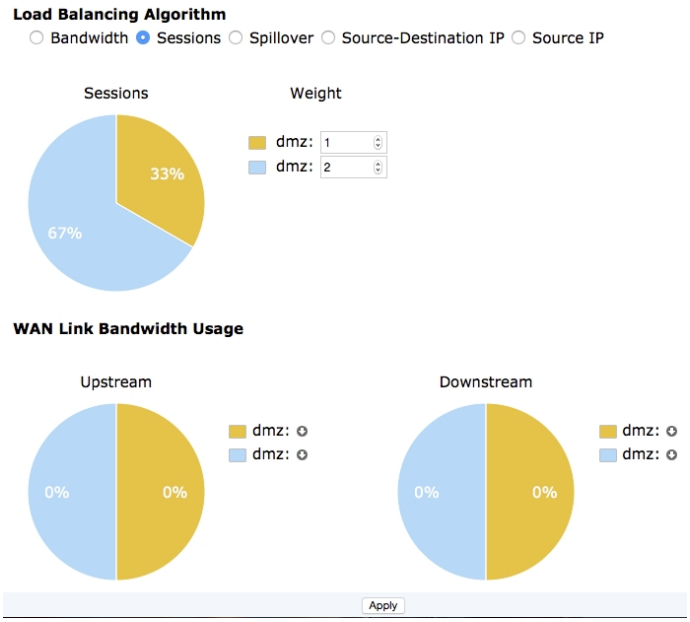
Example:

- There are 2 interfaces
- Interface #1 is assigned a weight of 5 because it is a 5 MB connection. (There is no requirement to match the weight to the capacity of the connection. It is just a simple way of optimizing the differing capacities in this case.)
- Interface #2 is assigned a weight of 3 because it is a 3 MB connection.
- The total weight is 8 so interface #1 gets 5/8 (63%) and interface #2 gets 3/8 (38%) of the traffic.



Sessions

The session algorithm is similar to the bandwidth algorithm in that it also uses an integer value to assign a weight to each interface. The difference is that the number of sessions connected is what is being measured and not the packets flowing through the interfaces.



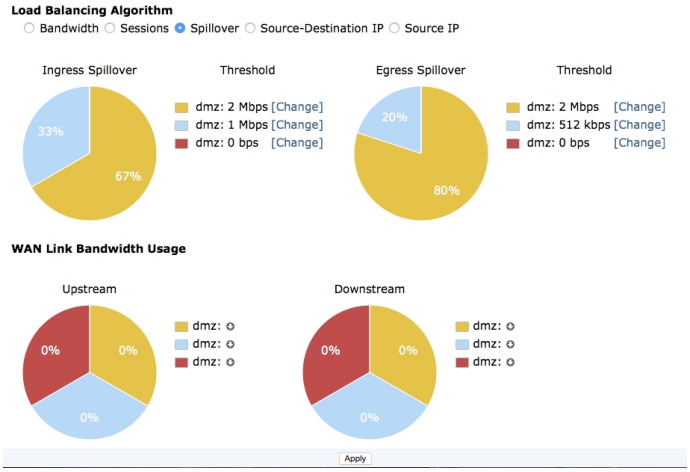
Spillover

Spillover is a method where a threshold is set for an interface (in kbps) and if the amount of traffic bandwidth exceeds the threshold any traffic bandwidth beyond that threshold is sent out through another interface.

It might be simple to just consider the outgoing or egress traffic when determining a threshold but two facts must be taken into consideration.

1. A simple request going out the interface can be responded to with significantly more data coming back from the other direction.
2. Internet connections come in a variety of configurations, many of which have different levels of allowed bandwidth capacity between the upload and download directions.

For these reasons, the FortiGate allows for the setting of both egress and ingress thresholds for bandwidth.



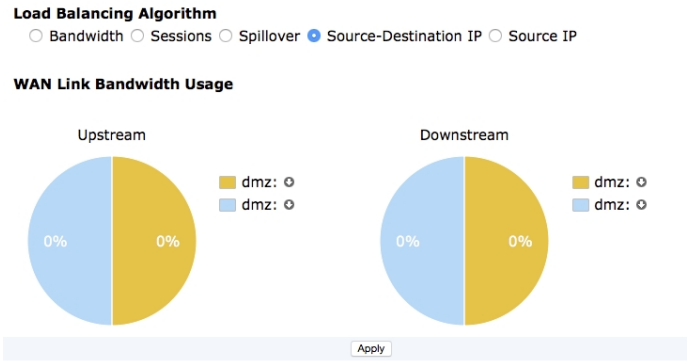
Source-destination IP

The source-destination IP algorithm tries to equally divide the traffic between the interfaces included in the virtual WAN interface. It used the connection criteria of the source and destination IP address combinations as a way of sorting the traffic.

Example:

- 10.10.10.10 to 1.1.1.2 gets sent out one interface
- Subsequent traffic going from 10.10.10.10 to 1.1.1.2 would also go out that same interface
- The next session to connect through the WAN could be either:
  - 10.10.10.27 going to 1.1.1.2
  - 10.10.10.10 going to 1.1.1.15.

Either one of the connections in the next session, even though they might match the source or the destination IP address do not match both. Traffic with the next unique combination of source and destination IP address would be sent out the other interface. It would go back and forth like this as new traffic and combinations comes in.



Source IP

The source IP address works just the same as the source-destination IP algorithm but it only concerns itself with the source IP address of the connection.

Avoid using WAN LLB in combination with asymmetric routing. Using the Bandwidth (GUI) or measure-based (CLI) load balancing algorithms can cause the routing-information (outgoing-interface) for sessions created in asymmetric routing to change in mid-session. Session-level persistence of the connection is needed to make WAN LLB effectively.

Priority rules

Some traffic requires that it come from a consistent or specific IP address to be processed properly. Because the different WAN interfaces will have different IP addresses there needs to be a way to override the unpredictability of the load balancing algorithms. This is done by using priority rules

Packets can be checked prior to being assigned an interface by the algorithm. If certain source and/or destination criteria matches the priority rules, the packets can be assigned to an outgoing interface as determined by the rule.

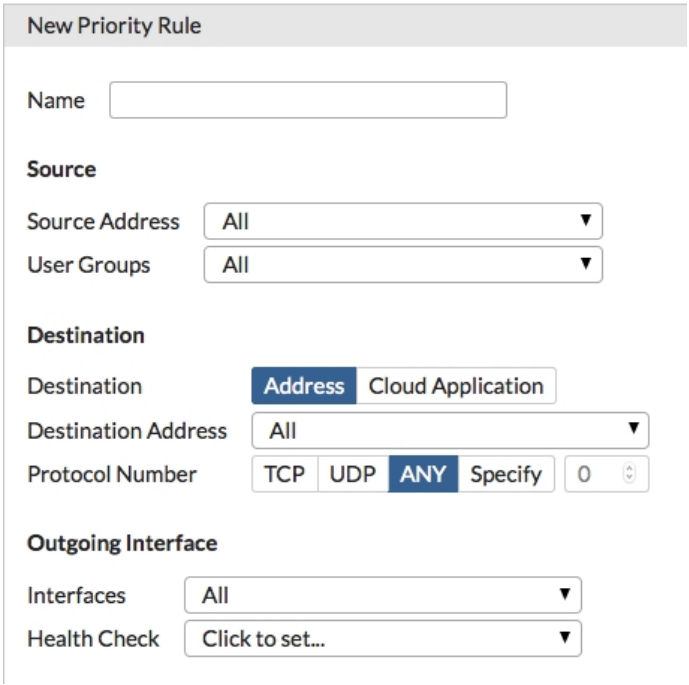
Priority rules can be configured under **Network > WAN LLB Rules**.

The source criteria that can be checked are:

- Source address
- User Group

The destination criteria that can be checked are:

- Whether it's address-based
  - Destination address
  - Protocol number
- Whether it's cloud application-based
  - The cloud application



Cloud applications

Cloud applications are a new object that can be used and configured on a FortiGate. There are a limited number of places that they can be used as a means of directing traffic and Virtual WAN links are one of them.

Estimated Bandwidth

An optional parameter has been added that allows users to set the estimated uplink and downlink bandwidths of a WAN interface.This setting is available in the GUI and the CLI. It's availability in the GUI is dependent on context. To see the setting when editing the interface, the role of the interface must be set to WAN.

The range of the setting is from 0 to 4294967295 (effectively 2^{32}). The value is in Kbps.

In the CLI, the fields can be set by using the following syntax:

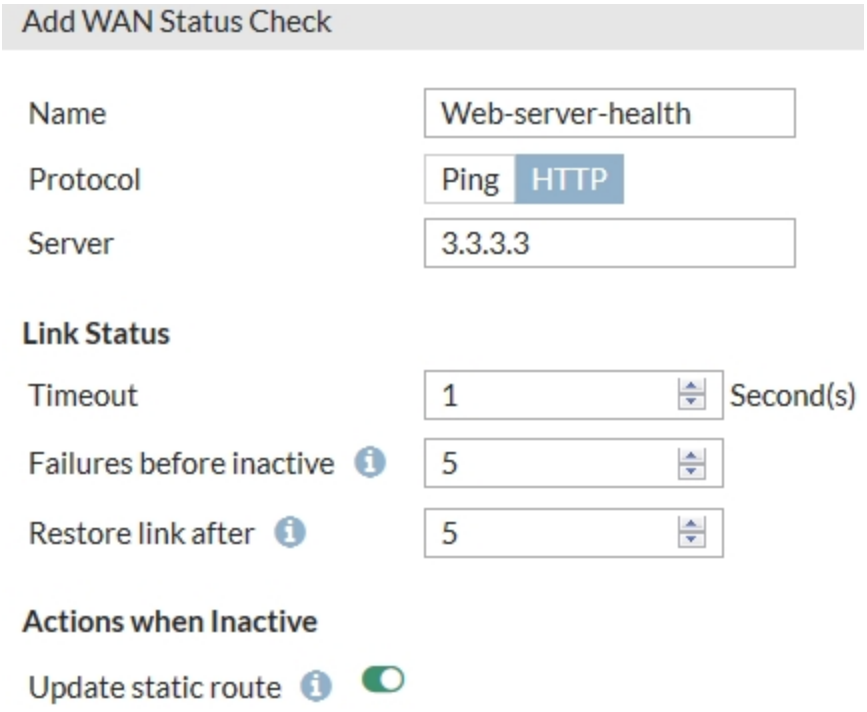
```
config system interface
   edit <wan interface>
      set estimated-upstream-bandwidth <integer from 0 - 4294967295>
      set estimated-downstream-bandwidth <integer from 0 - 4294967295>
      end
   end
```

The purpose for these settings is to work with monitoring software such as MRTG (Multi Router Traffic Grapher) to compare the estimated and real bandwith usage.This is not connected to threshold settings.

Status checking or health checking

For load balancing to be effective, there needs to be a constant monitoring of the health and status of the links that make up the virtual WAN link. Customized status checks can be configured to check on health of various aspects the traffic flow going through the link. Using either ICMP packets (PING) or HTTP requests to a designated server. Once the health reaches a specified threshold, the interface can be automatically removed from the virtual WAN link so that the algorithm is not sending traffic to a failed interface and bring down communications for a portion of the FortiGate's clientele.

To configure status or health checking go to Network > WAN Status Check and add status check profiles.



You can also configure status and health checking from the CLI. The CLI includes additional options for setting latency, jitter, and pack loss thresholds.

```
config system virtual-wan-link
   set fail-detect [enable | disable]
   set fail-alert-interfaces (available only if fail-detect is enabled)
   config health-check
      edit [Health check name]
         set server <string>
```

```
set protocol [ping | tcp-echo | udp-echo | http | twamp]
```

Some of the protocol options cause additional settings are made available.

http

```
set port
set http-get
set http-match
```

twamp

```
set port
set security-mode[none | authentication]
```

The `security-mode` setting authentication generates yet another potential setting, `password`.

```
set password
set packet-size
```

The next settings are available for all protocols

```
set interval <integer>
set timeout <integer>
set failtime [1 - 10]
set recoverytime [1 - 10]
set update-cascade-interface [enable | disable]
set update-static-route [enable | disable]
set threshold-warning-latency <integer 0-4294967295>
set threshold-alert-latency <integer 0-4294967295>
set threshold-warning-jitter <integer 0-4294967295>
set threshold-alert-jitter <integer 0-4294967295>
set threshold-warning-packetloss <integer 0-4294967295>
set threshold-alert-packetloss <integer 0-4294967295>
end
  end
end
```

Virtual-WAN-link improvements (365702)

Some new features have been incorporated into Virtual WAN Link to address the performance issues.

- The Virtual WAN link daemon only recalculates those services that have changed link quality.
- Removal of abnormal latency data.
- A link quality threshold has been added to prevent frequently route generation due to a small quality changes.
- Service ID field has been added
- A disable option is available for a service.
- Services in the CMDB are able to move and the order of policy routes in the kernel is based on the sequences of services in the CMDB.

Syntax for configuring a service ID

```
config system virtual-wan-link
   config service
      edit <service name>
            set id <integer between 0 - 255>
            end
```

Syntax for configuring the percentage threshold of change of link cost values that will result in a policy route generation

```
config system virtual-wan-link
   config service
      edit <service name>
            set link-cost-threshold <integer between 0 - 100000000>
            end
```

The default threshold is 10

Syntax for enabling | disabling a service

```
config system virtual-wan-link
   config service
      edit <service name>
            set status [enable | disable]
            end
```

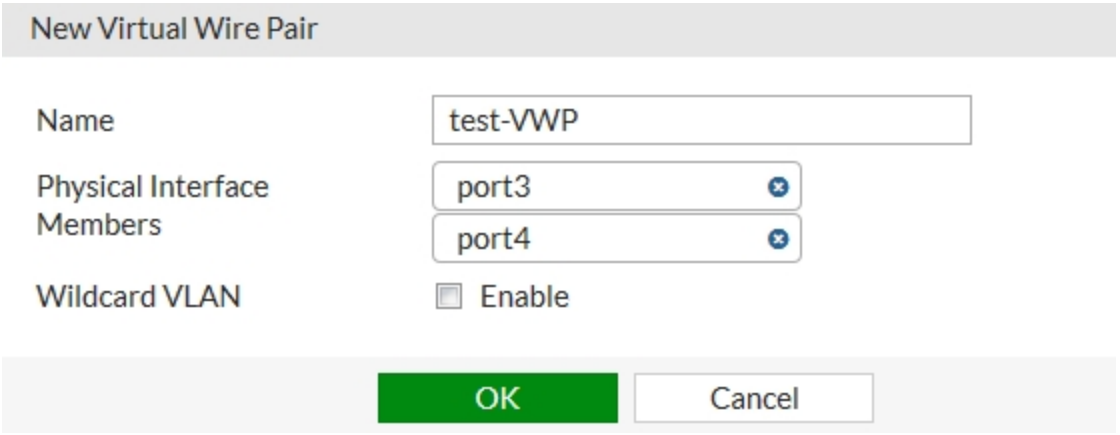
Virtual Wire Pair

This feature (276013), available in NAT and Transparent mode, replaces the Port Pair feature available in FortiOS 5.2 in Transparent mode only. When two physical interfaces are setup as a Virtual Wire Pair, they will have no IP addressing and are treated similar to a transparent mode VDOM. All packets accepted by one of the interfaces in a virtual wire pair can only exit the FortiGate through the other interface in the virtual wire pair and only if allowed by a virtual wire pair firewall policy. Packets arriving on other interfaces cannot be routed to the interfaces in a virtual wire pair. A FortiGate can have multiple virtual wire pairs.

You cannot add VLANs to virtual wire pairs. However, you can enable wildcard VLANs for a virtual wire pair. This means that all VLAN-tagged traffic can pass through the virtual wire pair if allowed by virtual wire pair firewall policies.

Adding a virtual wire pair

To add a virtual wire pair, go to **Network > Interfaces** and select **Create New > Virtual Wire Pair**. Select the interfaces to add to the virtual wire pair to, optionally enable Wildcard VLAN and select OK.



The virtual wire pair appears on the Interface list.

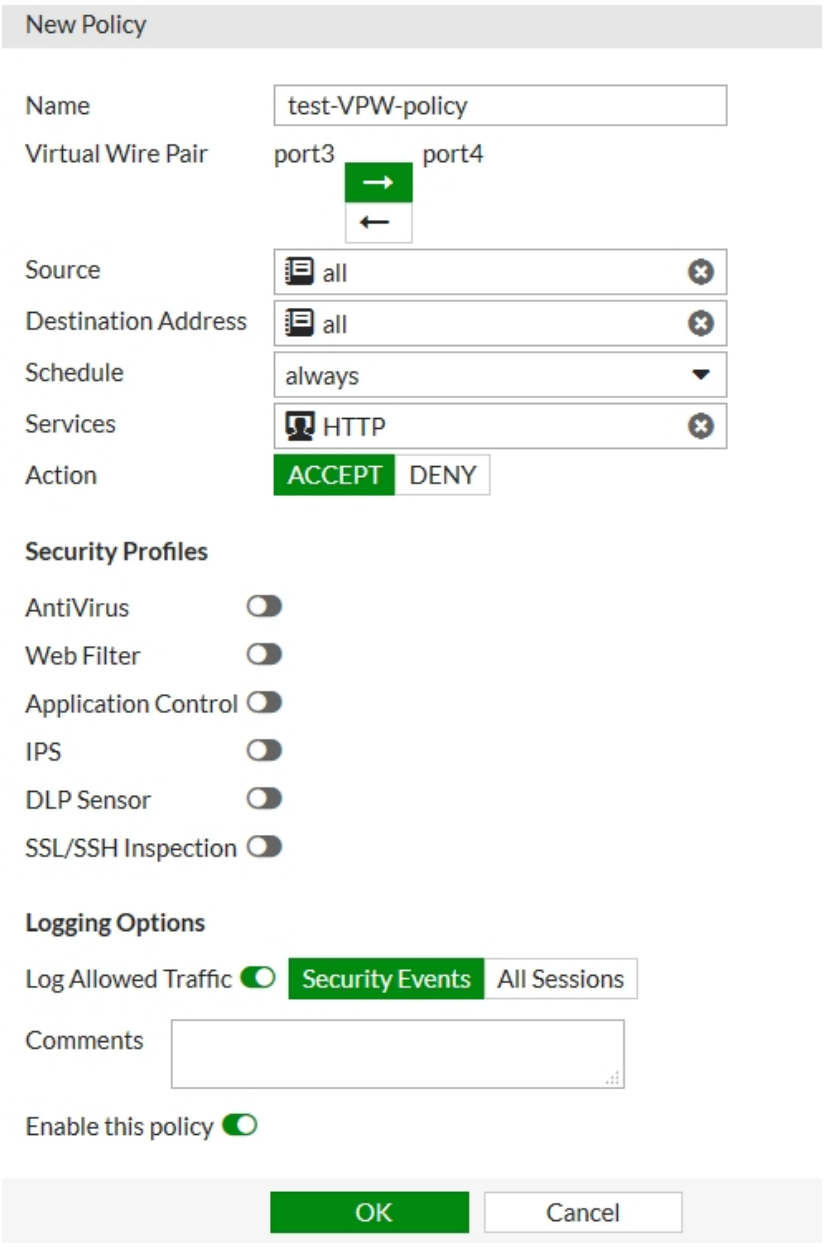
Use the following command to add a virtual wire pair from the CLI that enables the wildcard VLAN feature:

```
config system virtual-wire-pair
   edit test-VWP
      set member port3 port4
      set wildcard-vlan enable
   end
```

Assigning an interface to be part of a virtual wire pairing will remove the "role" value from the interface.

Adding a virtual wire pair firewall policy

You can add IPv4 and IPv6 virtual wire pair firewall policies. To add an IPv4 virtual wire pair firewall policy go to **Policy & Objects > IPv4 Virtual Wire Pair Policy**. Select the virtual wire pair that you want to add a policy for and select Create New. Start by configuring the direction of traffic though the policy and configure other policy settings like any firewall policy.



If you have a USB-wan interface, it will not be included in the interface list when building a wired pair.

Authentication

This chapter describes new authentication features added to FortiOS 5.4.

Support RSA-4096 bit key-length generation (380278)

In anticipation of quantum computers, RSA-4096 bit key-length CSRs can now be imported.

User authentication max timeout setting change (378085)

To accommodate wireless hotspot users authenticated on the FortiGate, the user authentication max timeout setting has been extended to 3 days (from 1 day, previously).

Changes to Authentication Settings > Certificates GUI (374980)

Added new icons for certificate types and updated formatters to use these new icons.

Support for changing a local certificate's password (297660)

Administrators can set a password through the CLI when generating a certificate request.

RADIUS CoA support (309499)

The following RADIUS CoA (Change of Authorization) CLI syntax has been added:

- Set the name of the FortiAP connected to the FortiGate as a location identifier.

CLI syntax

```
config system global
   set alias
```

- Set URL of external authentication logout server.

CLI syntax

```
config vdom
   edit root
      config wireless-controller vap
         edit <example>
            set security captive-portal
            set external-logout
```

- Set URL of external authentication logout server.

CLI syntax

```
config vdom
   edit root
      config system interface
         edit <example>
            set security captive-portal
            set security-external-logout
```

- Set class name(s) included in an Access-Accept message.

CLI syntax

```
config vdom
   edit root
      config user radius
         edit accounting
            set class <"A1=aaa" "B2=bbb" "C3=ccc">
```

You can now import PKCS12 certificates from the CLI (309934)

The following CLI syntax can be entered to import a local certificate file:

CLI Syntax

```
execute vpn certificate local import tftp <file name> <tftp ip address> <file type> <Enter
    for 'cer'>|<password for 'p12'>
```

For example:

```
execute vpn certificate local import tftp FGTF-extern.p12 10.1.100.253 p12 123456
```

RADIUS Framed-IP into accounting packets (234003 189828)

RADIUS attributes, including NAS-IP-Address, Called-Station-ID, Framed-IP-Address, and Event-Timestamp, are supported.

Include RADIUS attribute CLASS in all accounting requests (290577)

RADIUS attribute CLASS in accounting requests for firewall, WiFi, and proxy authentication is now supported. RADIUS attribute CLASS is returned in Access-Accept message and it is added to all accounting requests.

- If updating to 5.4.1, see above (309499).

Certificate-related changes (263368)

Fortinet_factory certificate has been re-signed with an expiration date of 2038 and it is used instead of fortinet_factory2, which has been removed.

Improvements and changes to per-VDOM certificates (276403 267362)

The CA and local certificate configuration is now available per-VDOM. When an admin uploads a certificate to a VDOM, it will only be accessible inside that VDOM. When an admin uploads a certificate to global, it will be accessible to all VDOMs and global.

There are factory default certificates such as Fortinet_CA_SSL, Fortinet_SSL, PositiveSSL_CA, Fortinet_Wifi, and Fortinet_Factory, these certificates are moved to per-VDOM and automatically generated when a new VDOM is created.

The Fortinet_Firmware certificate has been removed and all the attributes that use Fortinet_Firmware now use Fortinet_Factory.

CLI Changes

Two new attributes `range` and `source` have been added:

`range` can be global or per-VDOM, if the certificate file is imported from global, it is a global certificate. If the certificate file is imported from a VDOM, it is VDOM certificate.

`source` can be `factory`, `user` or `fortiguard`:

`factory`: The factory certificate file with FortiOS version, this includes: Fortinet_CA_SSL, Fortinet_SSL, PositiveSSL_CA, Fortinet_Wifi, Fortinet_Factory.

`user`: Certificate file imported by the user.

`fortiguard`: Certificate file imported from FortiGuard.

```
config certificate local
   edit Fortinet_Factory
      set range global/vdom
      set source factory/user/fortiguard
   end
end
```

GUI Changes

Global and per-VDOM certificate configuration includes **view details**, **download**, **delete**, and **import** certificate.

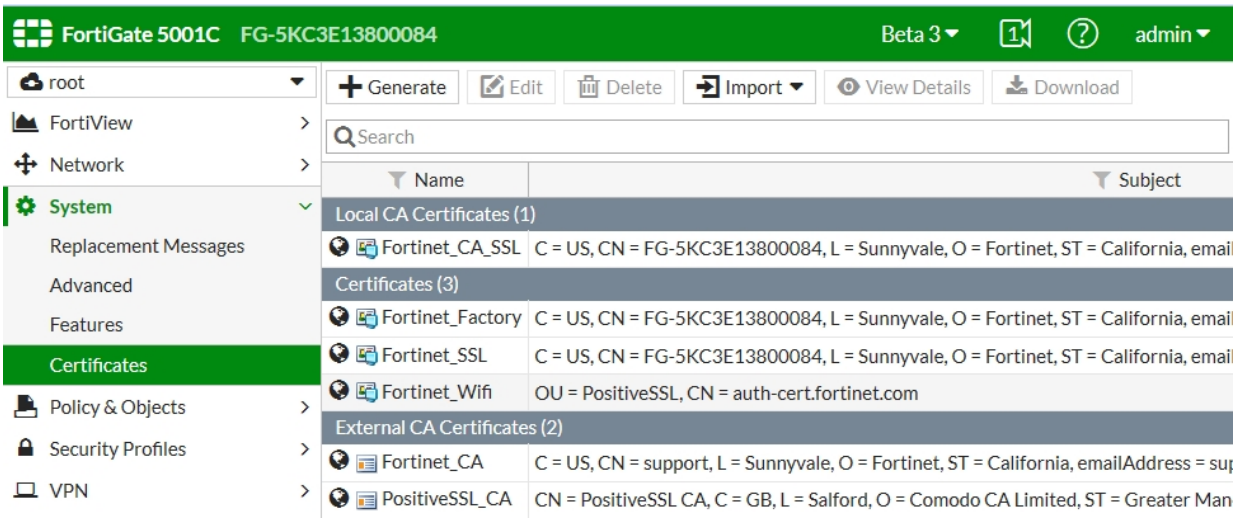
A **Source** and a **Status** columns have been added.

A global icon for **Name** column when VDOMs are enabled is added to show that the certificate is global.

A new VDOM now has the following default certificates: Fortinet_CA_SSL, Fortinet_Factory, Fortinet_SSL, Fortinet_Wifi, Fortinet_CA, and PositiveSSL_CA. These certificates are created automatically when the VDOM is created and every VDOM will have its own individual versions of these certificates.

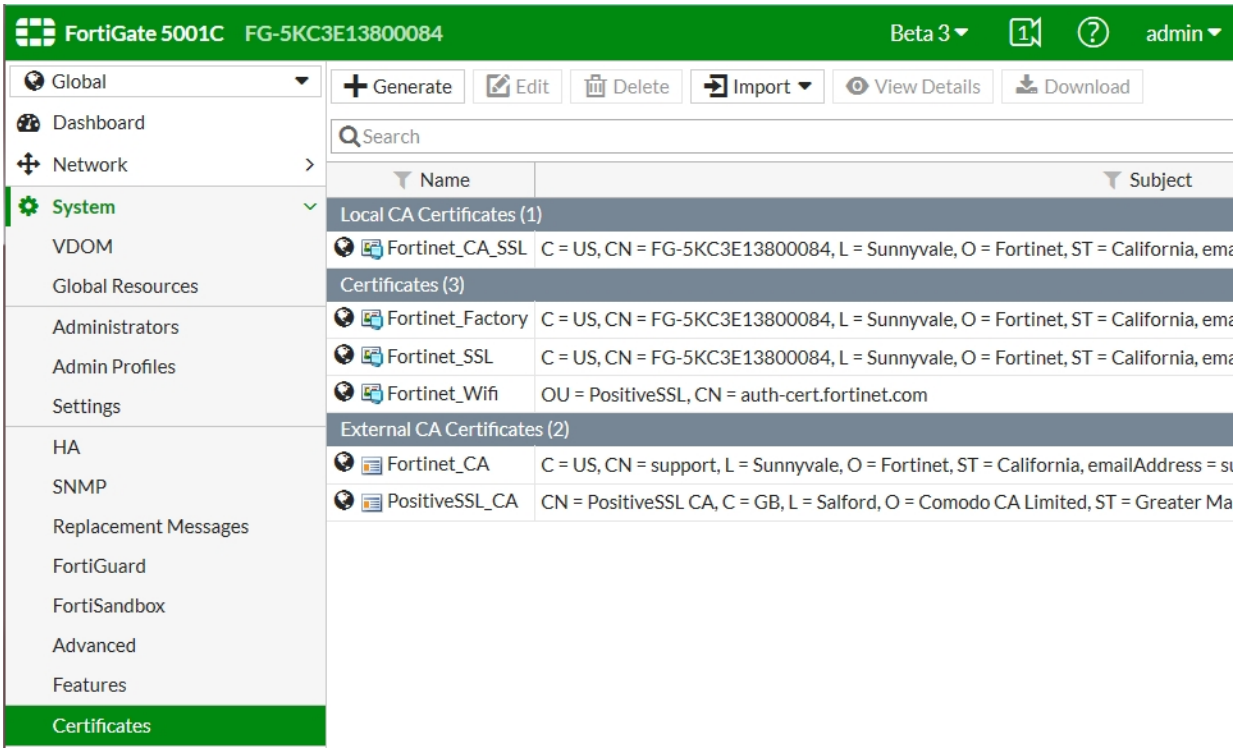
The Fortinet_firmware certificate has been removed. All default configurations that formerly used the Fortinet_ firmware certificate now use the Fortinet_Factory certificate.

Default root VDOM certificates



Certificates with the same names are also available from the global configuration. These are generated when you turn on VDOMs.

Default global certificates



Adding certificates to VDOMs and to the global configuration

If an administrator adds a certificate to a VDOM the certificate will only be available for that VDOM. If an administrator adds a certificate to the global configuration it will available for all VDOMs.

Guest user enhancements (291042)

The password policy profile for guest Admin is improved. This is a CLI only configuration as following:

```
config system password-policy-guest-admin
   status enable/disable Enable/disable password policy.
   apply-to guest-admin-password Guest admin to which this password policy applies.
   minimum-length  Minimum password length.
   min-lower-case-letter  Minimum number of lowercase characters in password.
   min-upper-case-letter  Minimum number of uppercase characters in password.
   min-non-alphanumeric Minimum number of non-alphanumeric characters in password.
   min-number  Minimum number of numeric characters in password.
   change-4-characters enable/disable Enable/disable changing at least 4 characters for new password.
   expire-status enable/disable Enable/disable password expiration.
   reuse-password enable/disable  Enable/disable reuse of password.
end
```

RADIUS CoA for user, user-group and captive-portal authentication (RFC 5176) (274813 270166)

RADIUS Change of Authorization (CoA) is a common feature in user authentication. User, user-group and captive-portal authentication now supports RADIUS CoA, when the back end authentication server is RADIUS.

The main use case of this feature is with external captive portal, it can be used to disconnect hotspot users when their time, credit or bandwidth had been used up.

- If updating to 5.4.1, see above (309499).

RSSO: Enable or disable overriding old attribute value when a user logs in again (possibly on a different device) (278471)

When receiving a new start message with different group name for the same user and different IP address such as the scenario of a mobile device roaming, the original design is to override all group name information to the latest group name received from the latest start message.

This new feature adds an option to disable this override when needed. The default behavior keeps the original design.

CLI changes

Add an option to enable or disable overriding SSO attribute value.

Syntax

```
config user radius
   edit <My_Rsso>
   set rsso enable
   set sso-attribute-value-override enable/disable // Enable/Disable override old attribute value
        with new value for the same endpoint.
```

```
end
```

FSSO supports Microsoft Exchange Server (270174)

FSSO supports monitoring Microsoft Exchange Server. This is useful for situation that the user use the domain account to access their email, but client device might or might not be in the domain. Support for Exchange server is configured on the Back-end FSSO collector agent under **Advanced Settings** > **Exchange Server**.

Select **Add** and enter the following information and select **OK**.

Domain Name	Enter your domain name.
Server IP/Hostname	Enter the IP address or the hostname of your exchange server.
Polling forwarded event log	This option for scenarios when you do not want that CA polls the Exchange Server logs directly. In this case you need to configure event log forwarding on the Exchange server. Exchange event logs can be forwarded to any member server. If you enable this, instead of the IP of the Exchange server configured in the previous step, you must then configure the IP of this member server. CA will then contact the member server.
Ignore Name	Because CA will also check Windows log files for logon events and when a user authenticates to Exchange Server there is also a logon event in Windows event log, which CA will read and this will overwrite the Exchange Server logon event (ES-EventLog) on CA. So it is recommended to set the ignore list to the domain the user belongs to. To do so, enter the domain name in the **Ignore Name** field and select **Add**.

PCI DSS compliance

This chapter describes new PCI DSS compliance features added to FortiOS 5.4.

Vulnerability Scanning has been removed (293156)

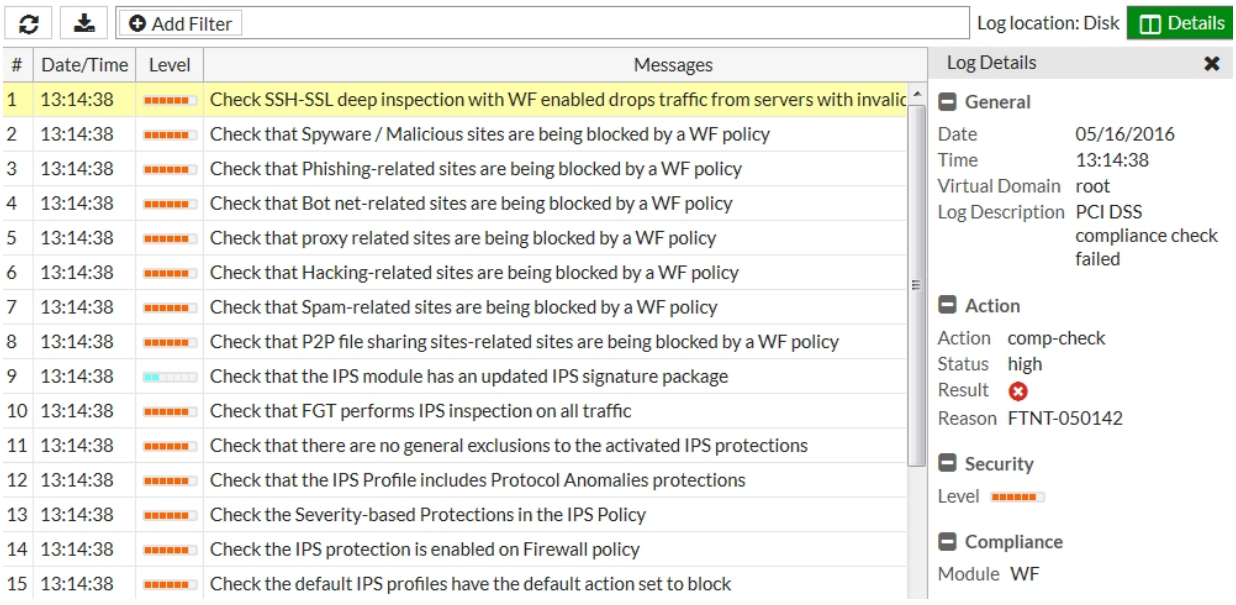
Vulnerability scanning can now be done from FortiClient.

PCI DSS Compliance Check Support (270014)

FortiOS 5.4 allows you to run a compliance check either on demand or according to a schedule that automatically checks PCI DSS compliance at the global or VDOM level. The compliance check determines whether the FortiGate is compliant with each PCI DSS requirement by displaying an 'X' next to the non-compliant entries in the GUI logs.

Go to **System > Advanced > Compliance**, turn on compliance checking and configure a daily time to run the compliance check. Or you can select **Run Now** to run the compliance check on demand.

Go to **Log & Report > Compliance Events** to view compliance checking log messages that show the results of running compliance checks.



Device identification

This chapter describes new Device Identification features added to FortiOS 5.4.

Passive detection of FortiFone, FortiCam and routers (304068)

Two new device groups types have been created in order to automatically provision FortiFone and FortiCam into different VLANs. Previously any FortiFone devices, and any FortiCam devices with a Fortinet MAC address, would have been included in the "Fortinet Devices" type.

These new device groups are found under **User & Device > Device List**.

802.1x Mac Authentication Bypass (197218)

Some FortiGate models contain a hardware switch. On the hardware switch interface, 802.1X authentication is available. You might want to bypass 802.1X authentication for devices such as printers that cannot authenticate, identifying them by their MAC addresses.

In the CLI, enable MAC authentication bypass on the interface:

```
config system interface
   edit "lan"
      set ip 10.0.0.200 255.255.255.0
      set security-mode 802.1X
      set security-mac-auth-bypass enable
      set security-groups "Radius-group"
   end
```

The devices that bypass authentication have entries in the RADIUS database with their MAC address in the User-Name and User-Password attributes instead of user credentials.

Vulnerability Scan status change(293156)

The FortiGate will no longer function as a vulnerability scanner, even in CLI mode. Vulnerability scans / assessments will handled by the FortiClient software.

FortiFone devices are now identified by FortiOS (289921)

FortiFone devices are now identified by FortiOS as **Fortinet FON**.

Support for MAC Authentication Bypass (MAB) (197218)

MAC Authentication Bypass allows devices without 802.1X capability (printers and IP phones for example) to bypass authentication and be allowed network access based on their MAC address. This feature requires RADIUS-based 802.1X authentication in which the RADIUS server contains a database of authorized MAC addresses.

MAC Authentication Bypass is configurable only in the CLI and only on interfaces configured for 802.1X authentication. For example:

```
config system interface
   edit "lan"
      set ip 10.0.0.200 255.255.255.0
```

```
      set vlanforward enable
      set security-mode 802.1X
      set security-mac-auth-bypass enable
      set security-groups "Radius-group"
   end
end
```

MAC Authentication Bypass is also available on WiFi SSIDs, regardless of authentication type. It is configurable only in the CLI. You need to enable the `radius-mac-auth` feature and specify the RADIUS server that will be used. For example:

```
config wireless-controller vap
   edit "office-ssid"
      set security wpa2-only-enterprise
      set auth usergroup
      set usergroup "staff"
      set radius-mac-auth enable
      set radius-mac-auth-server "ourRadius"
   end
end
```

Active device identification (279278)

Hosts whose device type cannot be determined passively are actively scanned using the same techniques as the vulnerability scan. This active scanning is enabled by default on models that support vulnerability scanning. You can turn off Active Scanning on any interface. In the GUI, go to the interface's page in **Network > Interfaces**.

CLI Syntax:

```
config system interface
   edit port1
      set device-identification enable
      set device-identification-active-scan disable
   end
```

Device Page Improvements (Detected and custom devices) (280271)

Devices are now in two lists on the **User & Device** menu. Detected devices are listed in the **Device List** where you can list them alphabetically, by type, or by interface. On the **Custom Devices and Groups** page you can

- create custom device groups
- predefine a device, assigning its device type and adding it to custom device groups

Device offline timeout is adjustable (269104)

A device is considered offline if it has not sent any packets during the timeout period. Prior to FortiOS 5.4, the timeout value was fixed at 90 seconds. Now the timeout can be set to any value from 30 to 31 536 000 seconds (365 days). The default value is 300 seconds (5 minutes). The timer is in the CLI:

```
config system global
   set device-idle-timeout 300
end
```

Improved detection of FortiOS-VM devices (272929)

A FortiGate-VM device is an instance of FortiOS running on a virtual machine (VM). The host computer does not have the Fortinet MAC addresses usually used to detect FortiGate units. Device detection now has two additional ways to detect FortiGate-VMs:

- the FortiGate vendor ID in FortiOS IKE messages
- the FortiGate device ID in FortiGuard web filter and spamfilter requests

Custom avatars for custom devices (299795)

You can upload an avatar for a custom device. The avatar is then displayed in the GUI wherever the device is listed, such as FortiView, log viewer, or policy configuration. To upload an avatar image,click Upload Image on the New Device or Edit Device page of **User & Device > Custom Devices & Groups**. The image can be in any format your browser supports and will be automatically sized to 36 x 36 pixels for use in the FortiGate GUI.

Diagnose command changes

This chapter describes new diagnose features added to FortiOS 5.4.

Antivirus diagnose command changes (299408)

There is a new diagnose command that shows antivirus database information.

```
diagnose antivirus database-info
```

This command shows:

- virus count
- grayware count
- signature count for antivirus databases.

The following antivirus diagnose commands have been removed:

```
diagnose antivirus heuristic showthreshold
diagnose antivirus heuristic showrules
diagnose antivirus virus list
```

Diagnose hardware test command supported on FortiGate-300D and 500D (302021)

The `diagnose hardware test` command with all of it options, replaces the functionality of the HQIP test firmware. Now hardware tests can be performed without installing an alternate firmware on the device. A listing of the options to this command can be found at http://wiki.diagnose.fortinet.com/index.php/diagnose_hardware_test.

This feature has been available on the E series FortiGates with 5.4 . It is now available in 5.4.1 on the FortiGate 300D and 500D models.

Option to skip interfaces in diagnose hardware test command (310778)

This diagnostic option allow specific interfaces to be skipped when perform performance tests on a FortiGate.

```
diag hardware test skip
```

One of the advantages of this method of hardware testing compared to the HQIP test, is that the device does not have to be shut down to run the tests. This advantage would be nullified if the running of the test brought down the functionality of the FortiGate. By skipping interfaces, tests can be run without impacting traffic.

This option of the diagnose hardware test command can be used with the following options.

`clear` - Clears the list of interfaces to be skipped during testing

`show` - Shows the current list of interfaces that are skipped during testing

`<interface>` - Includes an interface to the list of interfaces that are skipped during testing. This function is cumulative. Using the command to skip another interface does not replace the previous interface, it adds an additional one.

New diagnose sys top option (302607)

You can now enter the `diagnose sys top` command and include an option to control the number of times the command refreshes the listed processes before exiting.

The syntax for the command is now diagnose sys top <time between intervals> <number of processes> <number of intervals before quiting>

For example the following command displays 20 lines of output (the default), refreshes the display every 5 seconds (the default), and exits after refreshing the display 3 times.

```
diagnose sys top 5 20 3
```

By default the process list refreshes until you press "ctrl-c" or "q" to interrupt it. Setting a refresh limit is useful when you are using the command to gather information for Fortinet Support or for other reasons where you don't need the display to keep refreshing.

New diagnose command to display more detailed geographic information (310567)

Previously, there was a command that could return the country that an IPv4 address is located in.

```
diagnose geoip ip2country x.x.x.x
```

Now there is a command that will provide more granular information about the geographic location of an IPv4 address. I.e.not just the country, but the city or town as well.

```
diagnose geoip geoip-query x.x.x.x
```

Most diagnose sys dashboard commands removed (129248)

The `diagnose sys dashboard reset` command is still available.

FortiView network segmentation tree diagnose command (286116)

Enter `diagnose sys nst {downstream | query}` to display information about the FortiView network segmentation tree,

`downstream` shows connected downstream FortiGates.

`query` query the network segmentation tree.

Changes to diagnose hardware deviceinfo disk command (271816)

Extraneous information has been removed from the `diagnose hardware deviceinfo disk` command output and some field names have been changed.

Display the CLI schema (256892)

You can use these diagnose commands to display the CLI schema:

Enter `diagnose web-ui cli-schema` to display the entire schema.

Enter `diagnose web-ui cli-schema <branch-name>` to display just a single branch of the tree. For example, enter `diagnose web-ui cli-schema firewall policy` to dipslay the firewall policy schema.

New NP4 DDR diagnose command (261258)

Use the `diagnose np4 ddr` command to debug NP4 DDR settings.

```
diagnose npu np4 dqs-write
diagnosis npu np4 dqs-read <dev-id>
diagnosis npu np4 crps-write <dev-id> <CRPS>
```

```
diagnosis npu np4 crps-read <dev-id>
```

Ekahau site survey information to diagnose wireless wlac command (267384)

The output of the `diagnose wireless wlac` command includes information about Ehahau site survey results.

Port kernel profiling (237984)

Use the `diagnose sys profile {start | stop | show | sysmap | cpumask | module}` command to display port kernel profiling information.

`start` start kernel profiling data

`stop` copy kernel profiling data

`show` show kernel profiling result

`sysmap` show kernel sysmap

`cpumask` profile which CPUs

`module` show kernel module

Use the following steps:

1. set cpu mask first
2. run start command
3. run stop command to read the profiling data and analyze
4. run show command to show the result
5. set cpu mask 00 to stop profiling

List the most recently modified files (254827)

Use the `diagnose sys last-modified-files {path | number}` command to list the last (by default 10) modified files in a given directory.

`path` file system path from which to list modified files (default = /data).

`number` number of files to list (default = 10).

LTE modem diagnose command (279545)

```
dia test application lted <id>
```

Where `<id>` can be:

1. Show device info

2. Show data session connection status

3. Test connection

4. Test disconnection

5. Get signal strength

6. Get IP address

7. Get IP address and DNS server

8. Get SIM card status
9. Restart LTE device
10. Show LTED status
11. Resync LTED status
12. Check USB LTE/WiMAX configuration conflict
13. Stop monitor
14. Start monitor
15. List supported AT commands
16. Disable RF(Should stop monitor first)
17. Enable RF(Should start monitor first)
18. Get MIP information
19. Show current network service mode
20. Show current Channel/Bandclass
21. Show activation status
22. Show SIM status
23. Show registration status
24. Get IMEI
25. Get ICCID

New diagnose sys botnet command

Use the diagnose sys botnet {stat | list | find | flush | reload | file} command to display information about botnet information in the kernel and to flush and reload botnet information into the kernel.

`stat` the number of botnet entries in the kernel.

`list` list the botnet entries.

`find` find a botnet entry by ip address, port number, protocol etc.

`flush` flush botnet entries from the kernel.

`reload` reload botnet file into the kernel

`file` botnet file diagnostics.

Example command output:

```
diagnose sys botnet list
Read 10 botnet entry:
0. proto=TCP ip=0.175.57.24, port=80, name_id=8, rule_id=48
1. proto=UDP ip=1.22.117.135, port=16470, name_id=0, rule_id=32
2. proto=UDP ip=1.22.177.28, port=16465, name_id=0, rule_id=32
3. proto=UDP ip=1.22.213.38, port=16465, name_id=0, rule_id=32
4. proto=UDP ip=1.23.81.128, port=16465, name_id=0, rule_id=32
```

```
5. proto=UDP ip=1.23.82.125, port=16465, name_id=0, rule_id=32
6. proto=UDP ip=1.23.83.46, port=16465, name_id=0, rule_id=32
7. proto=UDP ip=1.23.83.138, port=16465, name_id=0, rule_id=32
8. proto=UDP ip=1.23.89.60, port=16465, name_id=0, rule_id=32
9. proto=UDP ip=1.23.128.18, port=16470, name_id=0, rule_id=32
```

Unquarantine all quarantined FortiClient devices (284146)

You can use the `diagnose endpoint registration unquarantine all` command to unquarantine all quarantined FortiClient devices.

Port HQIP to FortiOS using standard diagnose CLI (290272)

On FortiGate E series models, instead of downloading a special HQIP image to run hardware tests you can use the following command .

`diagnose hardware test`, followed by one of the following options:

- `bios` - perform BIOS related tests.
- `system` - perform system related tests.
- `usb` - perform USB related tests.
- `button` - perform button related tests.
- `cpu` - perform CPU related tests.
- `memory` - perform memory related tests.
- `network` - perform network related tests.
- `disk` - perform disk related tests.
- `led` - perform LED related tests.
- `wifi` - perform wifi related tests.
- `suite` - runthe HQIP test suite.
- `setting` - change test settings.
- `info` - show test parameters.

Access Control List (ACL) diagnose command (0293399)

Use the `diagnose firewall acl {counter | counter6 | clearcounter | clearcounter6}` command to display information about the access control list feature:

`counter` Show number of packets dropped by ACL.

`counter6` Show number of packets dropped by IPv6 ACL.

`clearcounter` Clear ACL packet counter.

`clearcounter6` Clear the IPv6 ACL packet counter.

New traffic test functionality (279363)

```
diagnose traffictest {show | run -h arg | server-intf | client-intf | port | proto}
```

Where -h arg can be

-f, --format [kmgKMG] format to report: Kbits, Mbits, KBytes, MBytes

-i, --interval # seconds between periodic bandwidth reports

-F, --file name xmit/recv the specified file

-A, --affinity n/n,m set CPU affinity

-V, --verbose more detailed output

-J, --json output in JSON format

-d, --debug emit debugging output

-v, --version show version information and quit

-h, --help show this message and quit

-b, --bandwidth #[KMG][/#] target bandwidth in bits/sec (0 for unlimited) (default %d Mbit/sec for UDP, unlimited for TCP) (optional slash and packet count for burst mode)

-t, --time # time in seconds to transmit for (default %d secs)

-n, --bytes #[KMG] number of bytes to transmit (instead of -t)

-k, --blockcount #[KMG] number of blocks (packets) to transmit (instead of -t or -n)

-l, --len #[KMG] length of buffer to read or write (default %d KB for TCP, %d KB for UDP)

-P, --parallel # number of parallel client streams to run

-R, --reverse run in reverse mode (server sends, client receives)

-w, --window #[KMG] TCP window size (socket buffer size)

-C, --linux-congestion <algo> set TCP congestion control algorithm (Linux only)

-M, --set-mss # set TCP maximum segment size (MTU - 40 bytes)

-N, --nodelay set TCP no delay, disabling Nagle's Algorithm

-4, --version4 only use IPv4

-6, --version6 only use IPv6

-S, --tos N set the IP 'type of service'

-L, --flowlabel N set the IPv6 flow label (only supported on Linux)

-Z, --zerocopy use a 'zero copy' method of sending data

-O, --omit N omit the first n seconds

-T, --title str prefix every output line with this string

--get-server-output get results from server

[KMG] indicates options that support a K/M/G suffix for kilo-, mega-, or giga-

New switch error counters for diagnose hardware deviceinfo nic command (285730)

New diag hardware deviceinfo flash command (300119)

To display flashprogram/erase count on 30D/60D/30E/50E/51E Platforms.

Explicit web proxy

This chapter describes new explicit web proxy features added to FortiOS 5.4.

Support Kerberos and NTLM authentication (370489)

FortiGate now recognizes the client's authentication method from the token and selects the correct authentication scheme to authenticate successfully.

CLI syntax

```
config firewall explicit-proxy-policy
   edit <example>
      set active-auth-method [ntlm | basic | digest | negotiate | none]
   end
```

Explicit Web Proxy WISP support improvements (309388 309236)

The following Explicit Web Proxy WISP CLI syntax has been changed and added:

- Changed web-proxy wisp to table object and added outgoing-ip.

CLI syntax

```
config web-proxy
   set server-ip // WISP server IP address
   set server-port // WISP server port (1 - 65535)
```

- In the web filter profile, added WISP servers and WISP algorithm.

CLI syntax

```
config webfilter profile
edit <example>
set wisp-servers // WISP servers
set wisp-algorithm // WISP server selection algorithm
```

Improvements to explicit web proxy policy page (305817)

Explicit proxy URL categories show description next to their numerical values in the CLI. Also, all categories for **URL Category** are available in the GUI.

Explicit web proxy Kerberos authentication support (297503)

The following web proxy Kerberos authentication CLI syntax has been added:

CLI syntax

```
config user krb-keytab
edit <example>
set principal // Kerberos service principal
set ldap-server // LDAP server name
set keytab // base64 coded keytab
```

Explicit proxy, Web Caching, and WAN Optimization are not supported for Flow-based VDOMs (274748)

Explicit proxy, web caching, and WAN optimization have been removed from the GUI in a Flow-based VDOM.

Explicit proxy support for base64 encoded X-Authenticated-Groups and X-Authenticated-User HTTP headers (356979)

Data for http header-names X-Authenticated-Groups and X-Authenticated-User are decoded before further processing.

New explicit proxy firewall address types (284753)

New explicit proxy firewall address types improve granularity over header matching for explicit web proxy policies. You can enable this option using the **Show in Address List** button on the Address and Address Group New/Edit forms under **Policy & Objects > Addresses**.

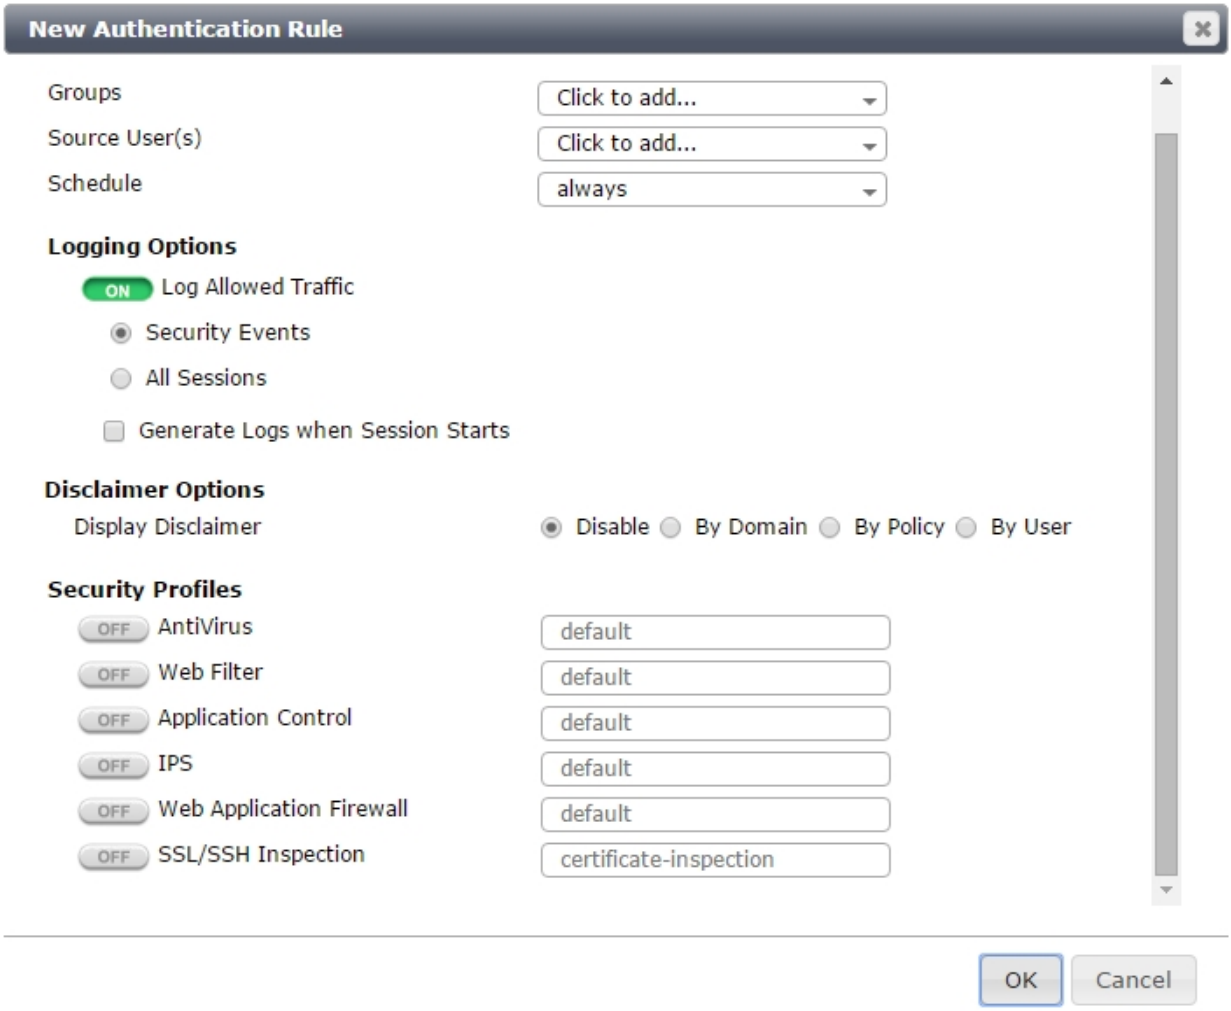
The following new address types have been added:

- **URL Pattern** - destination address
- **Host Regex Match** - destination address
- **URL Category** - destination address (URL filtering)
- **HTTP Method** - source address
- **User Agent** - source address
- **HTTP Header** - source address
- **Advanced (Source)** - source address (combines User Agent, HTTP Method, and HTTP Header)
- **Advanced (Destination)** - destination address (combines Host Regex Match and URL Category)

Disclaimer messages can be added to explicit proxy policies (273208)

Disclaimer options are now available for each explicit proxy policy or split policy of ID-based policy. This feature allows you to create user exceptions for specific URL categories (including warning messages) based on user groups.

The **Disclaimer Options** are configured under **Policy & Objects > Explicit Proxy Policy**. You can also configure a disclaimer for each Authentication Rule by setting **Action** to **Authenticate**.



Disclaimer explanations

- **Disable:** No disclaimer (default setting).
- **By Domain:** The disclaimer will be displayed on different domains. The explicit web proxy will check the referring header to mitigate the javascript/css/images/video/etc page.
- **By Policy:** The disclaimer will be displayed if the HTTP request matches a different explicit firewall policy.
- **By User:** The disclaimer will be displayed when a new user logs on.

Firewall virtual IPs (VIPs) can be used with Explicit Proxy policies (234974)

The explicit web-proxy will now accept VIP addresses for destination address. If an external IP matches a VIP policy, the IP is changed to the mapped-IP of the VIP.

Implement Botnet features for explicit policy (259580)

The option `scan-botnet-connections` has been added to the firewall explicit proxy policy.

Syntax:

```
config firewall explicit-proxy-policy
   edit <policyid>
      set scan-botnet-connections [disable/block/monitor]
end
```

where:

`disable` means do not scan connections to botnet servers.

`block` means block connections to botnet servers.

`monitor` means log connections to botnet servers.

Add HTTP.REFERRER URL to web filter logs (260538)

Added support for the referrer field in the HTTP header on webfilter log, this field along with others in the HTTP header are very useful in heuristic analysis /search for malware infected hosts.

Adding guest management to explicit web proxy (247566)

Allow user group with type **Guest** to be referenced in explicit-proxy-policy.

Firewall

This chapter describes new firewall features added to FortiOS 5.4.

Multiple interfaces or ANY interface can be added to a firewall policy (288984)

This feature can be enabled or disabled in the GUI by going to the **System > Feature Select** page and toggling **Multiple Interface Policies**.

When selecting the **Incoming** or **Outgoing** interface of a policy, there are a few choices:

- The ANY interface (choosing this will remove all other interfaces)
- A single specific interface
- multiple specific interfaces (can be added at the same time or one at a time)

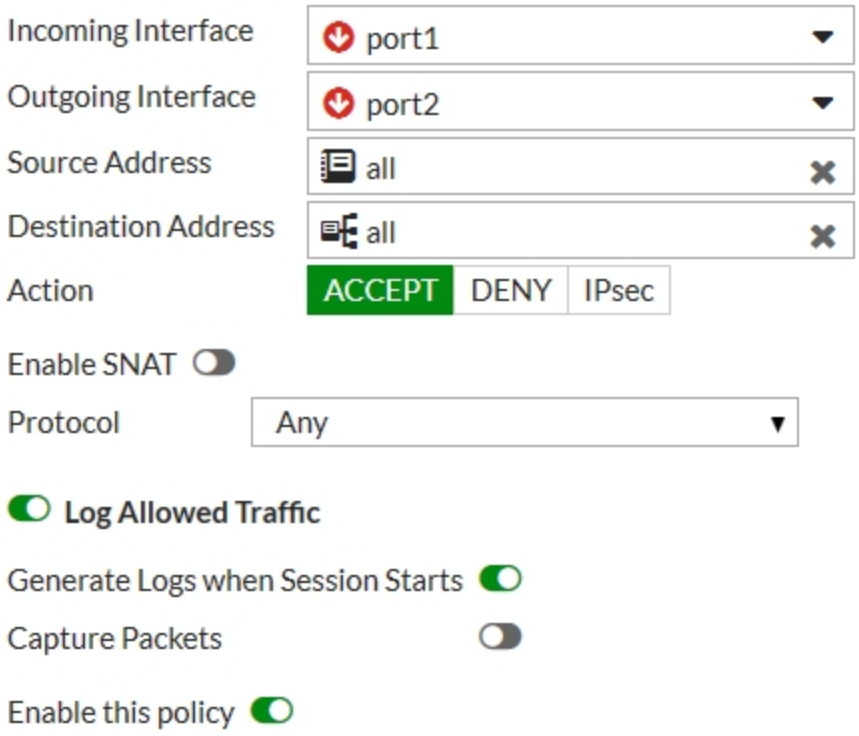
  The GUI is intuitive and straightforward on how to do this. Click on the "+" symbol in the interface field and then select the desired interfaces from the side menu. There are a couple of ways to do it in the CLI:

1. Set the interfaces all at once:
```
config firewall policy
   edit 0
      set srcintf wan1 wan2
      end
```
2. Set the first interface and append additional ones:
```
config firewall policy
   edit 0
      set srcintf wan1
      append srcintf wan2
      end
```

Multicast policy page changes (293709 305114)

The multicast policy GUI page has been updated to the new GUI look and feel. Some functionality has also been changed.

- The DNAT option has been removed from the GUI but is still in the CLI, you can set the action to IPsec, and if you select Log Allowed Traffic you can also select a few logging options.
- The Multicast policy page loads faster.



Policy objects dialogs updated to new GUI style (354505)

To avoid confusion, the default value for "day" is no longer Sunday. In the GUI, none of the day options are selected.

Display change in Policy listing (284027)

Alias names for interfaces, if used now appear in the headings for the Interface Pair View or what used to be called the Section View.

RPC over HTTP traffic separate (288526)

How protocol options profiles and SSL inspection profiles handle RPC (Remote Procedure Calls) over HTTP traffic can now be configured separately from normal HTTP traffic.

CLI syntax changes

```
config firewall profile-protocol-options
   edit 0
      set rpc-over-http {disable | enable}
   end

config firewall ssl-ssh-profile
   edit deep-inspection
      set rpc-over-http {disable | enable}
   end
```

Disable Server Response Inspection supported (274458)

Disable Server Response Inspection (DSRI) option included in Firewall Policy (CLI only) to assist performance when only using URL filtering as it allows the system to ignore the http server responses.

CLI syntax for changing the status of the DSRI setting:

```
conf firewall policy|policy6
   edit NNN
      set dsri enable/disable
      end

conf firewall interface-policy|interface-policy6
   edit NNN
      set dsri enable/disable
      end

conf firewall sniffer
   edit NNN
      set dsri enable/disable
      end
```

Policy counter improvements (277555 260743 172125)

- implicit deny policy counter added
- first-hit time tracked for each policy
- "Hit count" is tracked for each policy (total number of new sessions since last reset)
- Most counters now persist across reboots

Bidirectional Forwarding Detection (BFD) (247622)

Bidirectional Forwarding Detection (BFD) protocol support has been added to Protocol Independent Multicast (PIM), to detect failures between forwarding engines.

TCP sessions can be created without TCP syn flag checking (236078)

A Per-VDOM option is available to enable or disable the creation of TCP sessions without TCP SYN flag checking

Mirroring of traffic decrypted by SSL inspection (275458)

This feature sends a copy of traffic decrypted by SSL inspection to one or more FortiGate interfaces so that it can be collected by raw packet capture tool for archiving and analysis.

This feature is available if the inspection mode is set to flow-based. Use the following command to enable this feature in a policy. The following command sends all traffic decrypted by the policy to the FortiGate port1 and port2 interfaces.

```
conf firewall policy
   edit 1
      set ssl-mirror enable/disable
      set ssl-mirror-intf port1 port2
   next
```

Support for full cone NAT (269939)

Full cone NAT maps a public IP address and port to a LAN IP address and port. This means that a device on the Internet can send data to the internal LAN IP address and port number by directing it a the external IP address and port number. Sending to the correct IP address but a different port will cause the communication to fail. This type of NAT is also known as port forwarding.

Full cone NATing is configured only in the CLI. It is done by properly configuring an IP pool for the NATing of an external IP address. The two important settings are:

- `set type` - it must be set to `port-block-allocation` to use full cone
- `set permit-any-host` - enabling it is what enables full cone NAT

An example fo the IP pool configuration would be:

```
config firewall ippool
   edit "full_cone-pool1"
      set type port-block-allocation
      set startip 10.1.1.1
      set endip 10.1.1.1
      set permit-any-host enable
      end
```

Enable or disable inspecting IPv4 and IPv6 ICMP traffic (258734)

There is now a system setting that determines if ICMP traffic can pass through a Fortigate even if there is no existing session.

```
config system settings
   set asymroute-icmp enable
   set asymroute6-imap enable
   end
```

When feature enabled:

- Allows ICMP or ICMPv6 reply traffic can pass through firewall when there is no session existing - asymmetric routing case.

When feature disabled:

- Prevents ICMP or ICMPv6 replies from passing through firewall when there is no session existing.

Policy names (246575 269948 293048)

In addition to the Policy ID #, there is now a Policy name field in the policy settings. On upgrading to 5.4, policy names will not be assigned to old policies but when configuring new policies, a unique name must be assigned to it. Every policy name must be unique for the current VDOM regardless of policy type.

In the GUI, the field for the policy name is the first field on the editing page.

In the CLI, the syntax for assigning the policy name is:

```
config firewall [policy|policy6]
   set name <policy_name>
   end
```

The feature can be turned on or off.

To turn it off in the CLI:

```
config system settings
```

```
    set gui-advance-policy[enable|disable]
    end
```

To turn it off in the GUI, the ability to enable or disable it in the GUI must be enabled in the CLI.It is disabled by default.The syntax is:

```
config system settings
    set gui-allow-unamed-policy [enable | disable]
    end
```

Once it has been enabled, the requirement for named passwords can be relaxed by going to **System > Feature Select**. **Allow Unamed Policies** can be found under **Additional Features**.

This setting is VDOM based so if you are running VDOMs you will have to enter the correct VDOM before entering the CLI commands or turning the feature on or off in the GUI.

Policy and route lookup (266996 222827)

The **Policy Lookup** button in the menu bar at the top of the IPv4 and IPv6 Policy pages is used to determine the policy that traffic with a particular set of parameters will use. Once the parameters are entered, the policy that the traffic will use is displayed.

The parameters are:

- Source Interface - select from drop down menu of available interfaces
- Protocol - select from a drop down menu of:
  - IP
  - TCP
  - UDP
  - SCTP
  - [ICMP|ICMPv6]
  - [ICMP|ICMPv6] ping request
  - [ICMP|ICMPv6] ping reply
- Source - Source IP address
- Source Port
- Destination - Destination IP address
- Protocol Number - *if Protocol = IP*
- Source Port - *if Protocol = TCP|UDP|SCTP*
- Destination Port - *if Protocol = TCP|UDP|SCTP*
- ICMP Type - *if Protocol = ICMPv6*
- ICMP Code - *if Protocol = ICMPv6*

Support NAT 64 CLAT (244986)

NAT64 CLAT traffic is now supported by the FortiGate. CLAT traffic comes from devices that use the SIIT translator that plays a part in affecting IPv6 - IPv4 NAT translation.

VIPs can contain FQDNs (268876)

Instead of mapping to an IP address VIP can use a Fully Qualified Domain Name. This has to be configured in the CLI and the FQDN must be an address object that is already configured in the address listing.

The syntax for using a FQDN is as follows:

```
config firewall vip
   edit <VIP id>
      set type fqdn
      set mapped-addr <FQDN address object>
      end
```

Access Control Lists (ACLs) (293399)

The access control list (ACL) feature allows you to deny IPv4 or IPv6 packets received at an NP6-accelerated interface based on source and destination address and service. If you add an access control policy to an interface, ACL checking is one of the first things that happens to the packet and checking is done by the NP6 processor. The result is very efficient protection that does not use CPU or memory resources.

In the GUI, the feature can be found at **Policy & Objects > IPv4 Access Control List Policy & Objects > IPv6 Access Control List.**

To add an IPv4 ACL through the CLI use the following syntax:

```
config firewall acl
   edit <acl Policy ID #>
      set status enable
      set interface <interface>
      set srcaddr <address object>
      set dstaddr <address object>
      set service <service object>
      end
   end
```

To add an IPv6 ACL through the CLI use the following syntax:

```
config firewall acl6
   edit <acl Policy ID #>
      set status enable
      set interface <interface>
      set srcaddr <address object>
      set dstaddr <address object>
      set service <service object>
      end
   end
```

GUI improvement for DoS Policy configuration (286905)

The user can now set the **Action**, whether **Pass** or **Block**, for all of the anomalies in a list at once when configuring a DoS policy.Just choose the desired option in the heading at the top of the column.

Expired Policy Object warnings (259338)

The Policy window indicates when a policy has become invalid due to its schedule parameters referring only to times in the past.

FortiGate VM

This chapter describes new FortiGate VM features added to FortiOS 5.4.

FortiGate VM cloud-init integration (300398)

Cloud-init is a set of pythons scripts and utilities commonly used for multi-distribution of VMs into cloud environments.

With cloud-init integration, when users launch a new instance of Fortigate VM, they can:

- Upload a license to a FGT-VM
- Provide initial management configuration, e.g. IP, default gateway, DNS
- Set port configuration mode (DHCP or static)
- Provision initial firewall policies

Cloud-init documentation can be found at https://cloudinit.readthedocs.io/en/latest/

Allow VM tools (VMWare platform) to set network settings for FortiGate VMS (292248)

Changes have been made to the firmware to mitigate the following issues:

- FGVM does not allow IP configuration during deployment.
- The use of multiple OVF files for different network adapter types is redundant.
- The sequence of interfaces is not kept in consistent with network adapters in VM settings.

These issues are corrected by the following changes:

- During deployment, the user will be prompted for an IP allocation policy (when using the new vApp OVF file). Static/DHCP can be selected for each port. Gateway can be configured for port1. Hostname, as well as primary/secondary DNS address, can be configured.
- During deployment, the user will be able to select either E1000 virtual network adapter or VMXNET3 ones (when using the new vApp OVF file).
- The new process keeps FGTVM's interface in the same sequence as the order shown in VM settings.
- There is an added CLI command "`diag vmware show-ovfenv`" to print out the whole OVF environment.

All additional features during deployment are only available when FGTVM is deployed through vCenter as a vApp.

- FGTVM interface sequence is determined with the following logic (and priority):
  - If OVF environment is available, the sequence present in the OVF environment will be used. (This is the preferred case. As the sequence can kept consistent with VM settings, regardless of whether adapters are removed/added, or mixed types of adapters are used.)
  - If the first network adapter is VMXNET3, FGTVM will use a dynamic mapping of interface, according to the total number of network adapters present. (This assumes all the network adapters are VMXNET3.)
  - If the above conditions do not qualify, FGTVM will use a static mapping of interface, which assumes every network adapter is E1000
- Even when a fixed IP allocation policy is selected during deployment, DHCP might be enabled on port1. This happens when the interface IP is set to 0.0.0.0 on port1. Unfortunately, OVF environment is unable to provide

which IP allocation policy has been selected. Rather, it is only able to give a set of IP/netmask on each of the interfaces.

- Configuration is applied AFTER IP allocation policy. This means, IP allocation policy works as default settings of interface, and is ignored when any existing configuration presents on a certain interface.

FortiKVM removed from most FortiGates (366859)

The FortiKVM feature that allowed a virtual instance of FortiGate on a FortiGate device is no longer part of FortiOS for most models. With few exceptions, this feature is being moved to FortiHypervisor, a specialised appliance with resources optimized for the purpose.

FortiKVM support added to select models (282335)

FortiKVM functionality is now available on the following models:

- FGT1500D
- FGT3700D
- FGT3700DX
- FGT3810D

Interface assignment CLI:

```
config system vm
   edit 0
      set name vm1
         config interface
            edit 1
               set name vnic1
               set device [physical | vlan | softswitch]
               mode [bridge | passthrough]
               end
            end
         end
```

[device]: can assign physical, VLAN, or softwitch type host interface to this attribute.

[mode]: this attribute is available only when device is assigned physical type interface, bridge mode means several vNIC can share this interface, when packet arrives, host will lookup vNIC by dst mac address, in passthrough mode, host will send all packets to the vNIC, only one vNIC can use the physical interface in passthrough mode.

FGT-VM VMX (v2) (306438)

FortiGate-VM VMX version 2 allows for automated deployment of virtual FortiGate instances running FortiOS 5.4.1 in a specific VMWare SDN environment. For more details read the Release Notes and Admin Guides for FortiGate-VM VMX.

FortiOS On-Demand (308130)

New VM platform to support a consumption based FOS VM pricing model.FortiOS On-Demand supports VMWare hypervisor, and Openstack KVM hypervisor platforms.

- These platforms have three interfaces only: mgmt, port1, and port2.
- port1 and port2 are used for metering, and is reported to a FortiManager via the updated process.
- The FortiManager is configured externally via Vapp for VMware or user-data in KVM.

- FortiGuard updates and webfiltering servers will initially point to the FortiManager.
- The FortiManager will authorize the FOSVM instance. If not authorized the vdom is disabled.

Changes to FG-VM00 Min/Max Values (246780,372030)

- The maximum memory virtual memory has changed from 1 to 1.5 GB.
- The maximum number of VDOMs has changed from 1 to 2.

Integrate VMtools Into FortiGate-VM for VMware (248842)

The following VMtools sub set of features has been integrated into the FortiGate-VM for VMWare images:

- Start
- Stop
- Reboot
- IP state in vCenter

VM License Check Time Extension (262494)

VM license check time has been extended to 30 days, with daily warning notifications and a counter.

FortiGate VM Single Root I/O Virtualization (SR-IOV) support (275432)

SR-IOV is a specification that allows a PCIe device to be treated as multiple separate PCIe devices.This feature will enable better performance with Intel based servers across multiple VM platforms, including Citrix and AWS. In fact, AWS has optimized some instance types to take advantage of this feature.

You can reset FortiGate VMs to factory defaults without deleting the VM license (280471)

New command , **`execute factoryreset keepvmlicense`**, resets FortiGate VMs to factory defaults without deleting the VM license.

Hardware acceleration

This chapter describes new authentication features added to FortiOS 5.4.

Offload Diffie-Hellman processing for 3072- and 4096-bit Diffie-Hellman values (308040)

Server load balancing supports 3072 and 4096 bit DH values. The command syntax is:

```
config firewall vip
   edit server-name
      set type server-load-balance
      set server-type https
      set ssl-dh-bits {768 | 1024 | 1536 | 2048 | 3072 | 4096}
```

FortiGate models with CP9 processors support 3072 and 4096 DH bit sizes in hardware. All FortiGate models up to and including those with CP8 processors only support offloading DH bit sizes up to 2048 so any sizes larger than that are done in software and thus are relatively resource intensive.

NP6 diagnose commands and get command changes (288738)

You can use the `get hardware npu np6` command to display information about the NP6 processors in your FortiGate and the sessions they are processing. This command contains a subset of the options available from the `diagnose npu np6` command. The command syntax is:

```
get hardware npu np6 {dce <np6-id> | ipsec-stats | port-list | session-stats <np6-id> |
    sse-stats <np6-id> | synproxy-stats}
```

`<np6-id>` identifies the NP6 processor. `0` is `np6_0`, `1` is `np6_1` and so on.

`dce` show NP6 non-zero sub-engine drop counters for the selected NP6.

`ipsec-stats` show overall NP6 IPsec offloading statistics.

`port-list` show the mapping between the FortiGate's physical ports and its NP6 processors.

`session-stats` show NP6 session offloading statistics counters for the selected NP6.

`sse-stats` show hardware session statistics counters.

`synproxy-stats` show overall NP6 synproxy statistics for TCP connections identified as being syn proxy DoS attacks.

NP6 session accounting enabled when traffic logging is enabled in a firewall policy (268426)

By default, on a FortiGate unit with NP6 processors, when you enable traffic logging in a firewall policy this also enables NP6 per-session accounting. If you disable traffic logging this also disables NP6 per-session accounting. This behavior can be changed using the following command:

```
config system np6
   edit np6_0
      set per-session-accounting {disable | all-enable | enable-by-log}
   end
```

By default, `per-session-accounting` is set to `enable-by-log`, which results in per-session accounting being turned on when you enable traffic logging in a policy. You can disable per-session accounting or set `all-`

`enable` to enable per-session accounting whether or not traffic logging is enabled. Note that this configuration is set separately for each NP6 processor.

When offloaded sessions appear on the FortiView All Sessions console they include an icon identifying them as NP sessions:

Application	Bytes (Sent/Received)	Policy
TCP/443	29.16 kB	Local In
YouTube	NP 219.44 kB	my-policy
UDP/53	31.05 kB	Local In

You can hover over the NP icon to see some information about the offloaded sessions.

Determining why a session is not offloaded (245447)

You can use the `diagnose sys session list` command to get information about why a session has not been offloaded to an NP4 or NP6 processor.

If a session has not been offloaded the session information displayed by the command includes `no_ofld_reason` followed by information to help you determine the cause. To take a simple example, an HTTPS session connecting to the GUI could have a field similar to `no_ofld_reason: local`. This means the session is a local session that is not offloaded.

The `no_ofld_reason` field only appears if the session is not offloaded and includes information to help determine why the session is not offloaded. For example,

```
no_ofld_reason: redir-to-av redir-to-ips non-npu-intf
```

Indicates that the session is not offloaded because it was redirected to virus scanning (`redir-to-av`), IPS (`redir-to-ips`), and so on.

IPsec pass-through traffic is now offloaded to NP6 processors (253221)

IPsec traffic that passes through a FortiGate without being unencrypted is now be offloaded to NP6 processors.

Disabling offloading IPsec Diffie-Hellman key exchange (269555)

You can use the following command to disable using ASIC offloading to accelerate IPsec Diffie-Hellman key exchange for IPsec ESP traffic. By default hardware offloading is used. For debugging purposes or other reasons you may want this function to be processed by software.

Use the following command to disable using ASIC offloading for IPsec Diffie Hellman key exchange:

```
config system global
   set ipsec-asic-offload disable
end
```

FortiGate-3700DX TP2 processors support GTP offloading (294212)

The FortiGate-3700DX contains two TP2 processors that provide GTP offloading. GTPu traffic is forwarded from NP6 processors to TP2 processors. The TP2 processors filter the encapsulated traffic and send the approved GTPu traffic back to the NP6.

Preventing packet ordering problems with NP4 and NP6 FortiGates under heavy load (365497)

In some cases when FortiGate units with NP4 or NP6 processors are under heavy load the packets used in the TCP 3-way handshake of some sessions may be transmitted by the FortiGate in the wrong order resulting in the TCP sessions failing.

If you notice TCP sessions failing when a FortiGate with NP4 or NP6 processors is very busy you can enable `delay-tcp-npu-session` in the firewall policy receiving the traffic. This option resolves the problem by delaying the session to make sure that there is time for all of the handshake packets to reach the destination before the session begins transmitting data.

```
config firewall policy
   set delay-tcp-npu-session enable
end
```

High Availability

This chapter describes new high availability features added to FortiOS 5.4.

HA diagnose checksum command changes (259710)

The following diagnose commands changed:

- `diagnose sys ha showcsum` --> `diagnose sys ha checksum show`
- `diagnose sys ha csum-recalculate` --> `diagnose sys ha checksum recalculate`
- `diagnose sys ha cached-csum` --> `diagnose sys ha checksum cached`
- `diagnose sys ha cluster-csum` --> `diagnose sys ha checksum cluster`

FGCP supports BFD enabled BGP graceful restart after an HA failover (255574)

If an HA cluster is part of a Border Gateway Protocol (BGP) bidirectional forwarding detection (BFD) configuration where both the cluster and the BGP static neighbor are configured for graceful restart, after an HA failover BGP enters graceful restart mode and both the cluster and the BGP neighbor keep their BGP routes.

To support HA and BFD enabled BGP graceful:

- From the cluster, you can add a BFD enabled BGP neighbor as a static BFD neighbor using the `config router bfd` command. Set the BGP auto-start timer to 5 seconds so that after an HA failover BGP on the new primary unit waits for 5 seconds before connect to its BFD neighbors, and then registers BFD requests after establishing the connections. With static BFD neighbors, BFD requests and sessions can be created as soon as possible after the failover. The command `get router info bfd requests` shows the BFD peer requests.
- The BFD session created for a static BFD neighbor/peer request initializes its state as INIT instead of DOWN and its detection time as `bfd-required-min-rx * bfd-detect-mult` msecs.
- When a BFD control packet with a nonzero Your Discriminator (`your_discr`) value is received, if no session can be found to match the `your_discr`, instead of discarding the packet, other fields in the packet, such as addressing information, are used to choose one session that was just initialized, with zero as its remote discriminator.
- When a BFD session in the UP state receives a control packet with zero as Your Discriminator and DOWN as State, the session changes its state to DOWN but will not notify this DOWN event to BGP and/or other registered clients.

FRUP is not supported by FortiOS 5.4 (295198)

With the changes to switch mode, FRUP is no longer available on the FortiGate-100D.

VOIP application control sessions are no longer blocked after an HA failover (273544)

After an HA failover, VoIP sessions that are being scanned by application control will now continue with only a minor interruption, if any. To support this feature, IPS UDP expectation tables are now synchronized between cluster units.

Firewall local-in policies are supported for the dedicated HA management interface (276779 246574)

To add local in polices for the dedicated management interface, enable `ha-mgmt-inft-only` and set `intf` to `any`. Enabling `ha-mgmt-intf-only` means the local-in policy applies only to the VDOM that contains the dedicated HA management interface.

```
config firewall local-in-policy
   edit 0
      set ha-mgmt-intf-only enable
      set intf any
      etc...
   end
```

HA heartbeat traffic set to the same priority level as data traffic (276665)

Local out traffic, including HA heartbeat traffic, is now set to high priority to make sure it is processed at the same priority level as data traffic. This change has been made because HA heartbeat traffic can be processed by NP6 processors that are also processing data traffic. When HA heartbeat traffic was set to a lower priority it may have be delayed or dropped by very busy NP6 processors resulting in HA failovers.

FGSP CLI command name changed (262340)

The FortiOS 5.2 command `config system session-sync` has been changed in FortiOS 5.4 to `config system cluster-sync`. Otherwise the command syntax is the same and the `config system ha` commands used for FGSP settings have not changed.

FGSP now supports synchronizing IPsec sessions (262340)

The FGSP now synchronizes IPsec tunnels between FortiGates in an FGSP configuration. IPsec tunnel synchronization synchronizes keys and other run time data between the FortiGates in an FGSP configuration. No additional configuration is required to synchronize IPsec sessions. Also you cannot disable IPsec tunnel synchronization.

The FGSP synchronizes IPsec keys and other runtime data but not actual tunnel sessions. This means that if one of the cluster units goes down the cluster unit that is still operating can quickly get IPsec tunnels re-established without re-negotiating them but all existing tunnel sessions on the failed FortiGate have to be restarted on the still operating FortiGate.

IPsec tunnel sync only supports dialup IPsec. The interfaces on both FortiGates that are tunnel endpoints must have the same IP addresses and external routers must be configured to load balance IPsec tunnel sessions to the FortiGates in the cluster.

Monitoring VLAN interfaces (220773)

When operating in HA mode and if you have added VLAN interfaces to the FortiGates in the cluster, you can use the following command to monitor all VLAN interfaces and send a message if one of the VLAN interfaces is found to be down.

```
config system ha-monitor
   set monitor-vlan enable/disable
   set vlan-hb-interval <interval_seconds>
   set vlan-hb-lost-threshold <vlan-lost-heartbeat-threshold>
end
```

Once configured, this feature works by verifying that the primary unit can connect to the subordinate unit over each VLAN. This verifies that the switch that the VLAN interfaces are connected to is configured correctly for each VLAN. If the primary unit cannot connect to the subordinate unit over one of the configured VLANs the primary unit writes a link monitor log message indicating that the named VLAN went down (log message id 20099).

Improvements to the get system ha status command output (259416)

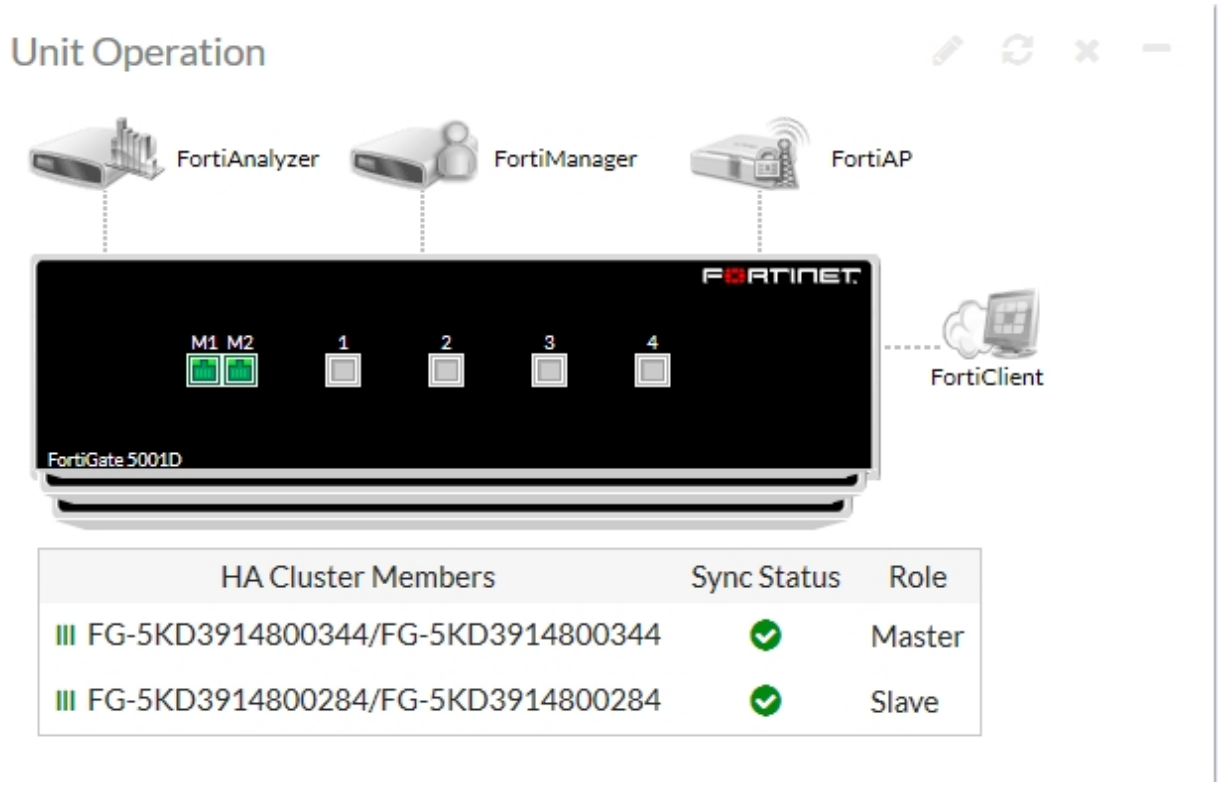
The get system ha status command now displays more information about cluster status including HA health status, cluster uptime, how the primary unit was selected and when this happened, override status, HA heartbeat interface activity, and CPU and memory usage for each cluster unit.

FortiGate HA cluster support for managed switches (276488 266084)

Added the capability to support managed switches from a FortiGate HA cluster. If a standby FortiGate becomes active, it automatically establishes connectivity with the managed switches.

HA cluster health displayed on the Unit Operation dashboard widget (260547)

The Unit Operation dashboard widget now includes the serial number and hostname of all of the FortiGate units in the cluster as well as an indication of the sync status of each cluster member.



IPsec VPN

This chapter describes new IPsec VPN features added to FortiOS 5.4.

Added warning message in IPsec VPN wizard if users selects ANY for peer ID (357043)

If users change the **peertype** setting back to **any**, either via CLI or GUI, they receive a warning that clearly informs them that using a setting of **any** will allow remote connections generated by any CA trusted by this FortiGate to be established.

- Warning icon shows up in IPsec tunnel page when setting **peertype** to **any** in VPN tunnel.
- Warning message shows up in IPsec tunnel editing page when setting **peertype** to **any** in VPN tunnel.
- In the VPN wizard configuration page, option **peer certificate CA** is added which is used to create the related peer user through VPN wizard.
- **Peertype** is set to **peer certificate** by default in GUI when setting **authmethod** to **signature** for custom IPsec tunnel.

IKEv1 Quick Crash Detection (304612)

Based on the IKEv2 quick crash detection (QCD) feature in Mantis 298970, which is already in the new features list for FortiOS 5.4 below.

There is no RFC for this feature. It is implemented using a new IKE vendor ID, "Fortinet Quick Crash Detection", and so both endpoints must be FortiGate devices. The QCD token is sent in the Phase 1 exchange and must be encrypted, so this is only implemented for IKEv1 in Main mode (Aggressive mode is not supported as there is no available AUTH message in which to include the token).

Otherwise, the feature works the same as in IKEv2 (RFC 6290).

IKE mode-cfg IPv4/IPv6 dual stack support (303550)

The previous IKE CLI uses the `mode-cfg-ip-version` option to specify whether `mode-cfg` should assign an IPv4 or IPv6 address, but this is not ideal for customers that require dual stack support.

As a solution in FortiOS 5.4.1, the `phase1 mode-cfg-ip-version` option was removed. The option was not necessary because the IP version can be determined by the selector type (`dst-addr-type`) of the configured Phase 2 tunnel(s). If the FortiGate client config contains Phase 2 tunnels for both IPv4 and IPv6, then the FortiGate client will request IPv4 and IPv6 addresses during `mode-cfg`.

Additionally, the FGT server can now be configured to reply with either or both IPv4 and IPv6, as per the client's `mode-cfg` request.

Security improvements to the default IPsec VPN signature and peer type configuration (304894 307500 307490 355149)

New features have been introduced to make certification and implementation in IPsec VPN more secure by default. Users can now create PKI certificates in-line in the VPN editor.

In short:

- Reimplemented PKI dialogs such that changes to enforce attributes are done in new frameworks
- Changed default templates for VPN wizard to enforce `peertype=any` so that wizard tunnels can be created
- Will now default to PKI string when creating signature VPN via VPN edit

Remote IP address change detection (209553)

This feature changes the way IPsec SAs are tracked in the kernel in order to detect external IP address changes in the tunnel.

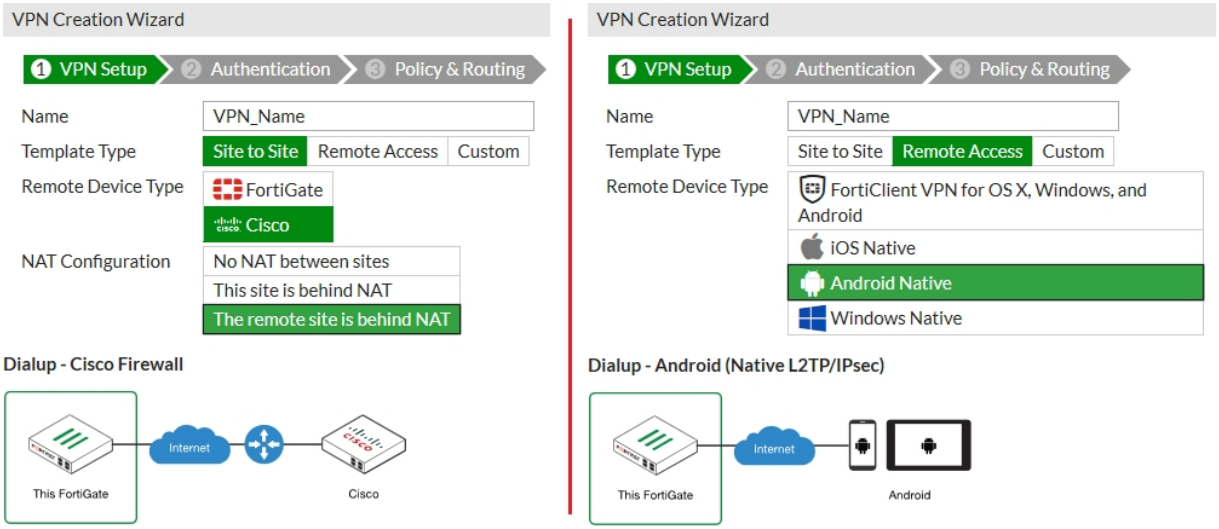
Previously, SAs were stored when keyed off of the remote IP address. Now, SAs are stored in a hash table when keyed off the IPsec SA SPI value (which is actually more RFC compliant). This enables the FortiGate, for each inbound ESP packet received, to immediately look up the SA and compare the stored IP address against the one in the incoming packet. If the incoming and stored IP addresses differ, an IP address change can be made in the kernel SA, and an update event can be triggered for IKE.

IKE/IPsec Extended Sequence Number (ESN) support (255144)

This feature implements negotiation of 64-bit Extended Sequence numbers as described in RFC 4303, RFC 4304 as an addition to IKEv1, and RFC 5996 for IKEv2.

Updates and enhancements to the IPsec VPN wizard (222339 290377 287021 289251)

The IPsec VPN wizard has been simplified to more clearly identify tunnel template types, remote device types, and NAT configuration requirements. Example topological diagrams are now also included.



New **Dialup - FortiGate** and **Dialup - Windows (Native L2TP/IPsec)** tunnel template options.

Cisco compatible keep-alive support for GRE (261595)

The FortiGate can now send a GRE keep-alive response to a Cisco device to detect a GRE tunnel. If it fails, it will remove any routes over the GRE interface.

Syntax

```
config system gre-tunnel
   edit <id>
      set keepalive-interval <value: 0-32767>
```

```
      set keepalive-failtimes <value: 1-255>
   next
end
```

Repeated Authentication in Internet Key Exchange (IKEv2) Protocol (282025)

This feature provides the option to control whether a device requires its peer to re-authenticate or whether re-key is sufficient. It does not influence the re-authentication or re-key behavior of the device itself, which is controlled by the peer (with the default being to re-key).

This solution is in response to RFC 4478. As described by the IETF, "the purpose of this is to limit the time that security associations (SAs) can be used by a third party who has gained control of the IPsec peer".

Syntax

```
config vpn ipsec phase1-interface
   edit p1
      set reauth [enable | disable]
   next
end
```

Improvements to IPsec VPN in ADVPN hub-and-spoke (275322)

IPsec VPN traffic is now allowed through a tunnel between an ADVPN hub-and-spoke

```
config vpn ipsec phase1-interface
   edit "int-fgtb"
      ...
      set auto-discovery-sender [enable | disable]
      set auto-discovery-receiver [enable | disable]
      set auto-discovery-forwarder [enable | disable]
      ...
   next
end
config vpn ipsec phase2-interface
   edit "int-fgtb"
      ...
      set auto-discovery-sender phase1 [enable | disable]
      ...
   next
end
```

ADVPN support for NAT device (299798)

The ADVPN feature has been extended so that it allows ADVPN shortcuts to be negotiated as long as one of the devices is not behind NAT.

The on-the-wire format of the ADVPN messages was changed so that they use TLV encoding. Since the on-the-wire format has changed this is not compatible with any previous ADVPN builds.

AES-GCM support (281822)

AES-GCM (128 | 256) AEAD has been added, as specified in **RFC 4106**:

```
config vpn ipsec phase1-interface
   edit "tofgta"
```

```
      ...
      set suite-b disable | suite-b-gcm-128 | suite-b-gcm-256
      ...
   next
end
config vpn ipsec phase2-interface
   edit "tofgta"
      set phase1name "tofgta"
      set proposal aes128gcm aes256gcm
      ...
   next
end
```

IPsec tunnel idle timer (244180)

Add a command to define an idle timer for IPsec tunnels when no traffic has passed through the tunnel for the configured idle-timeout value, the IPsec tunnel will be flushed.

```
config vpn ipsec phase1-interface
   edit p1
      set idle-timeout enable/disable
      set idle-timeoutinterval <integer> //IPsec tunnel idle timeout in minutes (10 - 43200).
   end
end
```

SAs negotiation improvement (245872)

The IPsec SA connect message generated is used to install dynamic selectors. These selectors can now be installed via the auto-negotiate mechanism. When phase 2 has auto-negotiate enabled, and phase 1 has mesh-selector-type set to **subnet**, a new dynamic selector will be installed for each combination of source and destination subnets. Each dynamic selector will inherit the auto-negotiate option from the template selector and begin SA negotiation. Phase 2 selector sources from dial-up clients will all establish SAs without traffic being initiated from the client subnets to the hub.

Add VXLAN over IPsec (265556)

Packets with VXLAN header are encapsulated within IPsec tunnel mode. New attributes in IPsec phase1 settings have been added.

```
config vpn ipsec phase1-interface/phase1
   edit ipsec
      set interface <name>
      set encapsulation vxlan/gre (new)
      set encapsulation-address ike/ipv4/ipv6 (New)
      set encap-local-gw4 xxx.xxx.xxx.xxx (New)
      set encap-remote-gw xxx.xxx.xxx.xxx (New)
   next
end
```

Ability to enable/disable IPsec ASIC-offloading (269555)

Much like NPU-offload in IKE phase1 configuration, this feature enables/disables the usage of ASIC hardware for IPsec Diffie-Hellman key exchange and IPsec ESP traffic. Currently by default hardware offloading is used. For

debugging purposes, sometimes we want all the traffic to be processed by software.

```
config sys global
   set ipsec-asic-offload [enable | disable]
end
```

Added an option to force IPsec to use NAT Traversal (275010)

Added a new option for NAT. If NAT is set to Forced, then the FGT will use a port value of zero when constructing the NAT discovery hash for the peer. This causes the peer to think it is behind a NAT device, and it will use UDP encapsulation for IPsec, even if no NAT is present. This approach maintains interoperability with any IPsec implementation that supports the NAT-T RFC.

Add a feature to support IKEv2 Session Resumption described in RFC 5723 (289914)

If a gateway loses connectivity to the network, clients can attempt to re-establish the lost session by presenting the ticket to the gateway. As a result, sessions can be resumed much faster, as DH exchange that is necessary to establish a brand new connection is skipped. This feature implements "ticket-by-value", whereby all information necessary to restore the state of a particular IKE SA is stored in the ticket and sent to the client.

Added support for IKEv2 Quick Crash Detection (298970)

A new feature has been added to support IKEv2 Quick Crash Detection as described in RFC 6290.

RFC 6290 describes a method in which an IKE peer can quickly detect that the gateway peer that it has and established IKE session with, has rebooted, crashed, or otherwise lost IKE state. When the gateway receives IKE messages or ESP packets with unknown IKE or IPsec SPIs, the IKEv2 protocol allows the gateway to send the peer an unprotected IKE message containing INVALID_IKE_SPI or INVALID_SPI notification payloads.

RFC 6290 introduces the concept of a QCD token, which is generated from the IKE SPIs and a private QCD secret, and exchanged between peers during the protected IKE AUTH exchange.

CLI Syntax

```
config system settings
   set ike-quick-crash-detect [enable | disable]
end
```

- If updating to FortiOS 5.4.1, see above (304612).

Removed support for auto-IPsec (300893)

IPsec auto-VPN support (auto-IPsec) has been removed. This feature was added in FortiOS 5.0 prior to any usable VPN creation support on the GUI. As of 5.2, and now in 5.4, the wizard solves many of the problems introduced by the auto-IPsec feature, and so auto-IPsec has been deprecated.

Improved scalability for IPsec DPD (292500)

On a dial-up server, if a multitude of VPN connections are idle, the increased DPD exchange could negatively impact the performance/load of the daemon. For this reason, an option has been added to send DPD passively in

a mode called "on-demand".

```
config vpn ipsec phase1-interface
   edit <value>
      set dpd [disable | on-idle | on-demand]
   next
end
```

Notes

- When there is no traffic and the last DPD-ACK had been received, IKE will not send DPDs periodically.
- IKE will only send out DPDs if there are outgoing packets to send but no inbound packets had since been received.

Syntax

The `set dpd enable` command has changed to `set dpd on-idle` (to trigger DPD when IPsec is idle). Set DPD to `on-demand` to trigger DPD when IPsec traffic is sent but no reply is received from the peer.

```
configure vpn ipsec phase1-interface
   edit <value>
      set dpd [on-idle|on-demand]
   next
end
```

IPv6

DHCPv6 server is configurable in delegated mode (295007)

Downstream IPv6 interfaces can receive address assignments on delegated subnets from a DHCP server that serves an upstream interface.

DHCPv6-PD configuration

Enable DHCPv6 Prefix Delegation on upstream interface (port10):

```
config system interface
   edit "port10"
     config ipv6
       set dhcp6-prefix-delegation enable
     end
end
```

Assign delegated prefix on downstream interface (port1). Optionally, specific delegated prefixes can be specified:

```
config system interface
   edit "port1"
     config ipv6
       set ip6-mode delegated
       set ip6-upstream-interface "port10"
       set ip6-subnet ::1:0:0:0:1/64
       set ip6-send-adv enable
       config ipv6-delegated-prefix-list
         edit 1
           set upstream-interface "port10"
           set autonomous-flag enable
           set onlink-flag enable
           set subnet 0:0:0:100::/64
         end
     end
   end
```

DHCPv6 Server configuration

Configuring a server that uses delegated prefix and DNS from upstream:

```
config system dhcp6 server
   edit 1
     set dns-service delegated
     set interface "wan2"
     set upstream-interface "wan1"
     set ip-mode delegated
     set subnet 0:0:0:102::/64
   end
```

FortiGate can connect to FortiAnalyzer using IPv6 addresses (245620)

When configuring your FortiGate to send logs to a FortiAnalyzer you can specify an IPv4 or an IPv6 address.

IPv6 neighbor discovery limits changes(248076)

You can use the following command to configure the maximum number of IPv6 neighbors that can be discovered by the IPv6 Neighbor Discovery Protocol (NDP) and added to the IPv6 neighbor database.

```
config system global
   set ndp-max-entry <integer>
end
```

The number of entries can be in the range 65,536 to 2,147,483,647. The default value of 0 means 65,536 entries.

Support IPv6 blackhole routing (220101)

Similar to IPv4 blackhole routing, IPv6 blackhole routing is now supported. Use the following command to enable IPv6 blackhole routing:

```
config router static6
   edit 1
      set blackhole enable/disable
   next
end
```

TFTP session helper for IPv6 (263127)

TFTP is supported over nat66 and nat46.

FTP, PPTP and RTSP session helper enhancements for IPv6 (244986)

The FTP, PPTP and RTSP session helpers support NAT-64 customer-side translator (CLAT) sessions.

Central Management ratings and update servers can use IPv6 addresses (297144)

You can configure servers for Central Management using either IPv4 or IPv6 addresses. The `addr-type` field sets the address type. The address is entered in the `server-address` or `server-address6` field as appropriate.

```
config system central-management
   set type fortimanager
   set fmg "2000:172:16:200::207"
   set vdom "vdom1"
   config server-list
      edit 1
         set server-type rating update
         set addr-type ipv6
         set server-address6 2000:172:16:200::207
      end
   end
```

Allow asymmetric routing for ICMP (258734)

Where network topology requires asymmetric routing for ICMP traffic, you can configure the FortiGate to permit the asymmetric ICMP traffic. This is done in the CLI. There are separate fields for IPv4 and IPv6 versions of ICMP.

```
config system settings
   set asymroute-icmp enable
   set asymroute-icmp6 enable
end
```

Load balancing

This chapter describes new load balancing features added to FortiOS 5.4.

Separate virtual-server client and server TLS version and cipher configuration (308040)

In previous versions of FortiOS you can configure minimum and maximum SSL/TLS versions that a virtual server will accept. Those versions primarily applied to the client to FortiGate connection; but, they are also applied to the FortiGate to server connection. In some cases you may want to use different versions of SSL or TLS on the client to FortiGate connection than on the FortiGate to server connection. For example, you may want to use the FortiGate to protect a legacy SSL 3.0 or TLS 1.0 server while making sure that client to FortiGate connections must always use the higher level of protection offered by TLS 1.1 or greater.

Similarly in previous versions of FortiOS you could control the cypher suites that can be used by the FortiGate to negotiate with the client and with the server. But you could only configure the same configuration for both client and server connections. Also, in some cases you might want to protect a server that only has weak ciphers (for example, DES or RC4) while making sure that all connections between the FortiGate and the client use a strong cipher for better protection.

The following new options are available when configuring server load balancing for HTTPS sessions configured with the following command:

```
config firewall vip
   edit server-name
      set type server-load-balance
      set server-type https
      set ssl-mode full
      ...
```

Different SSL/TLS versions for server and client connections

New `ssl-server-min-version` and `ssl-server-max-version` configuration options allow the minimum and maximum SSL/TLS versions for the client to FortiGate connection to be independent of the FortiGate to server configuration. By default these options are both set to `client` and the configured `ssl-min-version` and `ssl-max-version` settings are applied to both the client and the server connection.

You can change the `ssl-server-min-version` and `ssl-server-max-version` to apply different options to the server connection. The `ssl-min-version` and `ssl-max-version` settings are still applied to the client connection. If you set the `ssl-server-min-version` and `ssl-server-max-version` to an explicit version then both must be set to an explicit version.

The `ssl-server-min-version` and `ssl-server-max-version` options allow you to specify the minimum and maximum SSL/TLS versions the FortiGate will offer to the server (in the record header of the ClientHello) when performing full mode SSL offloading and thus the minimum and maximum SSL/TLS versions the FortiGate accepts from the server (in a ServerHello). If the server responds with a version in its ServerHello that is lower than `ssl-server-min-version` or higher than the `ssl-server-max-version` then the FortiGate terminates the connection.

Command syntax is:

```
config firewall vip
   edit server-name
      set type server-load-balance
```

```
set server-type https
set ssl-mode full
set ssl-min-version {ssl-3.0 | tls-1.0 | tls-1.1 | tls-1.2}
set ssl-max-version {ssl-3.0 | tls-1.0 | tls-1.1 | tls-1.2}
set ssl-server-min-version {ssl-3.0 | tls-1.0 | tls-1.1 | tls-1.2 | client}
set ssl-server-max-version {ssl-3.0 | tls-1.0 | tls-1.1 | tls-1.2 | client}
```

Different cipher choices for server and client connections

New `ssl-server-algorithm` configuration option allows the cipher choice for the FortiGate to server connection to be independent of the client to FortiGate connection. By default, `ssl-server-algorithm` is set to `client` and the configured `ssl-algorithm` setting is applied to both the client and the server connection.

You can change the `ssl-server-algorithm` to apply different options to the server connection. The `ssl-algorithm` setting is still applied to the client connection.

The following `ssl-server-algorithm` options are available:

- `high`, offer AES or 3DES cypher suites in the ServerHello
- `medium`, use AES, 3DES, or RC4 cypher suites in the ServerHello
- `low`, use AES, 3DES, RC4, or DES cypher suites in the ServerHello
- `custom`, specifiy custom cypher suites using the `config ssl-server-cipher-suites` and offer these custom cypher suites in the ServerHello.
- `client`, offer the cypher suites in the ServerHello that are offered in the ClientHello.

Command syntax is:

```
config firewall vip
   edit server-name
      set type server-load-balance
      set server-type https
      set ssl-mode full
      set ssl-algorithm {high | medium | low | custom}
      set ssl-server-algorithm {high | medium | low | custom | client}
```

If you set ssl-server-algorithm to custom, the syntax is:

```
config firewall vip
   edit server-name
      set type server-load-balance
      set server-type https
      set ssl-mode full
      set ssl-server-algorithm custom
         config ssl-server-cipher-suites
            edit 10
               set cipher <cipher-suite>
               set versions {ssl-3.0 | tls-1.0 | tls-1.1 | tls-1.2}
            next
            edit 20
               set cipher <cipher-suite>
               set versions {ssl-3.0 | tls-1.0 | tls-1.1 | tls-1.2}
            end
         end
```

Protection from downgrade attacks

The new `ssl-client-fallback` option, when enabled (the default configuration), performs downgrade attack prevention (RFC 7507).

Command syntax is:

```
config firewall vip
   edit server-name
      set type server-load-balance
      set server-type https
      set ssl-client-fallback {disable | enable}
```

Allow 3072- and 4096-bit Diffie-Hellman values

New settings added to the `ssl-dh-bits` option to allow 3072 and 4096 bit DH values.

Command syntax is:

```
config firewall vip
   edit server-name
      set type server-load-balance
      set server-type https
      set ssl-dh-bits {768 | 1024 | 1536 | 2048 | 3072 | 4096}
```

The reason for adding these larger sizes is that the previous largest value of 2048 only provides the equivalent of a symmetric cipher in the range of 112 - 128 bits. This means that if AES 256 is used then the weakest point is the DH of 2048 and at least a value of 3072 should be use if the goal is to have 256 bits of security.

FortiGate models with CP9 processors support 3072 and 4096 DH bit sizes in hardware. All FortiGate models up to and including those with CP8 processors only support offloading DH bit sizes up to 2048 so any sizes larger than that are done in software and thus are relatively resource intensive.

ChaCha20 and Poly1305 cipher suites added for SSL load balancing (264785)

FortiOS 5.4 adds support for ChaCha20 and Poly1305 for SSL load balancing (see RFC 7539 for information about ChaCha20 and Poly1305). You can use the following command to view the complete list of supported cipher suites:

```
config firewall vip
   edit <vip-name>
      set type server-load-balance
      set server-type https
      set ssl-algorithm custom
         config ssl-cipher-suites
            edit 0
            set cipher ?
```

In most configurations the matching cipher suite is automatically selected.

All of these cipher suites are available to all of FortiOS's implementations of SSL but the complete list of supported cipher suites is only viewable using the above command.

You can also use the above command to limit the set of cipher suites that are available for a given SSL offloading configuration. For example, use the following command to limit an SSL load balancing configuration to use the three cipher suites that support ChaCha20 and Poly1305:

```
config firewall vip
   edit <vip-name>
      set type server-load-balance
      set server-type https
      set ssl-algorithm custom
         config ssl-cipher-suites
            edit 1
            set cipher TLS-ECDHE-RSA-WITH-CHACHA20-POLY1305-SHA256
            next
            edit 2
            set cipher TLS-ECDHE-ECDSA-WITH-CHACHA20-POLY1305-SHA256
            next
            edit 3
            set cipher TLS-DHE-RSA-WITH-CHACHA20-POLY1305-SHA256
            end
         end
```

TLS 1.2 support for SSL offloading (241817)

You can use the following command to configure SSL offloading to support TLS 1.2:

```
config firewall vip
   edit <name>
      set type server-load-balance
      set server-type https
      set ssl-min-version {ssl-3.0 | tls-1.0 | tls-1.1 | tls-1.2}
      set ssl-max-version {ssl-3.0 | tls-1.0 | tls-1.1 | tls-1.2}
      ...
```

The default `ssl-min-version` is `tls-1.0` and the default `ssl-max-version` is `tls-1.2`.

The following AES-GCM TLS 1.2-only cipher suites have also been added. These cipher suites are not supported by the CPx or NPx processors so if you select one of these, all processing is done without hardware acceleration.

TLS 1.2 support does not require setting `ssl-algorithm` to `custom` and configuring a custom cipher suite.

```
TLS-DHE-RSA-WITH-AES-128-GCM-SHA256
TLS-DHE-DSS-WITH-AES-128-GCM-SHA256
TLS-DHE-RSA-WITH-AES-256-GCM-SHA384
TLS-DHE-DSS-WITH-AES-256-GCM-SHA384
TLS-ECDHE-RSA-WITH-AES-128-GCM-SHA256
TLS-ECDHE-RSA-WITH-AES-256-GCM-SHA384
TLS-ECDHE-ECDSA-WITH-AES-128-GCM-SHA256
TLS-ECDHE-ECDSA-WITH-AES-256-GCM-SHA384
TLS-RSA-WITH-AES-128-GCM-SHA256
TLS-RSA-WITH-AES-256-GCM-SHA384
```

You can use the following command to select one of these cipher suites:

```
config firewall vip
```

```
edit <name>
   set type server-load-balance
   set server-type https
   set ssl-max-version tls-1.2
   set ssl-algorithm custom
      config ssl-cipher-suites
         edit 100
            set cipher TLS-DHE-RSA-WITH-AES-128-GCM-SHA256
            ...
```

Logging and Reporting

This chapter describes new logging and reporting features added to FortiOS 5.4.

A new error log message is recorded when the Antispam engine request does not get a response from FortiGuard (265255)

Error code is '*sp_ftgd_error*'.

New Report database construction (280398 267019)

This will improve performance with reports and FortiView without requiring any configuration changes.

Communication between FortiGate and FortiAnalyzer supports IPv6 addresses (245620)

When configuring your FortiGate to send logs to a FortiAnalyzer you can specify an IPv4 or an IPv6 address.

Context menu on Log & Report > Forward Traffic has been updated (293188)

Now includes Policy Table and Device Quarantine controls.

Filtering allows control of the log messages sent to each log device (262061)

This includes disk log, memory log, FortiAnalyzer and syslog servers and allows inclusion/exclusion based on type, severity, and log ID.

Use the following CLI command:

```
config log <device> filter
   set filter <new-filter-settings>
   set filter-type <include | exclude>
end
```

Log messages in plain text LZ4 compressed format (271477 264704)

Log messages are stored on disk and transmitted to FortiAnalyzer as plain text in LZ4 compressed format. This change improves performance and reduces disk log size and reduces log transmission time and bandwidth usage.

Action and Security Action fields are improved (282691)

Action and Security Action fields in logs more clearly distinguishing between different uses of Action. Examples include traffic blocking by policy versus traffic blocking by security profile, or different result messages of Actions such as initiating session.

Log disk is full Event logs are deleted last (251467)

This feature should improve troubleshooting and diagnostics.

Send log messages to up to four syslog servers (279637)

You can use the CLI command `config log {syslogd | syslogd2 | syslogd3 | syslogd4}` to configure up to four remote syslog servers.

Changes to SNMP MIBs add the capability of logging dynamic routing activity (168927)

Examples include sending OSPF routing events or changes to a syslog server or FortiAnalyzer or changes in neighborhood status.

The syntax in the CLI for enabling the feature on BGP, OSPF and OSPF for IPv6 is as follows:

```
config router bgp
   set log-neighbour-changes [enable | disable]
   end

config router ospf
   set log-neighbour-changes [enable | disable]
   end

config router ospf6
   set log-neighbour-changes [enable | disable]
   end
```

Improve dynamic routing event logging (231511)

Major dynamic routing events such as neighbor down/up for BGP and OSPF are logged, without having to evoke debugging commands.

Adding option for VDOM logs through management VDOM (232284)

FortiOS supports the definition of per VDOM FortiAnalyzers. However it is required that each VDOM logs independently to its FortiAnalyzer server.

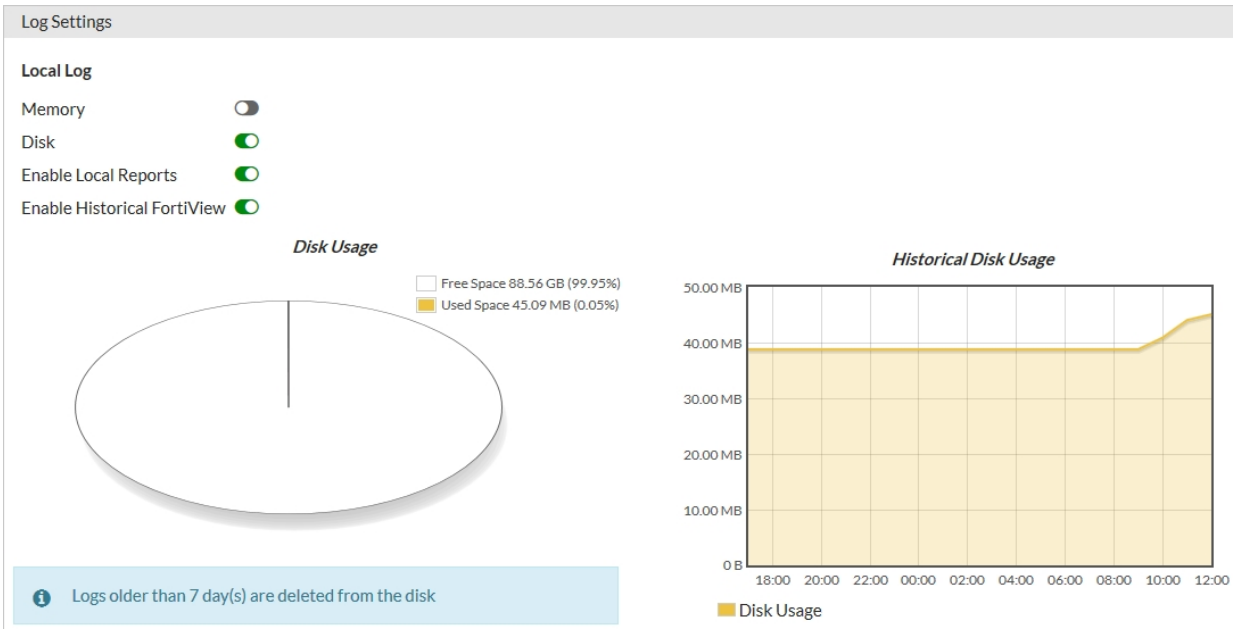
A new option, `use-management-vdom`, has been added to the CLI.

```
config vdom
   edit xxx
      config log fortianalyzer override-setting
         set use-management-vdom enable/disable
      end
   end
```

If this option is enabled, source-ip will become hidden and when FortiGate sends logs to FortiAnalyzer, it uses management vdom ip setting as source ip. Also if IPsec is enabled, the tunnel is created in management vdom and source ip belongs to management vdom.

The Log Settings GUI page displays information about current log storage (271318)

The Log Settings GUI page (Log & Report > Log Settings) displays information about current log storage including the amount of space available on the selected storage location and so on.



Log backup and restore tools (265285)

Local disk logs can now be backed up and restored, using new CLI commands.

```
exec log backup <filename>
exec log restore <filename>
```

Restoring logs will wipe the current log and report content off the disk.

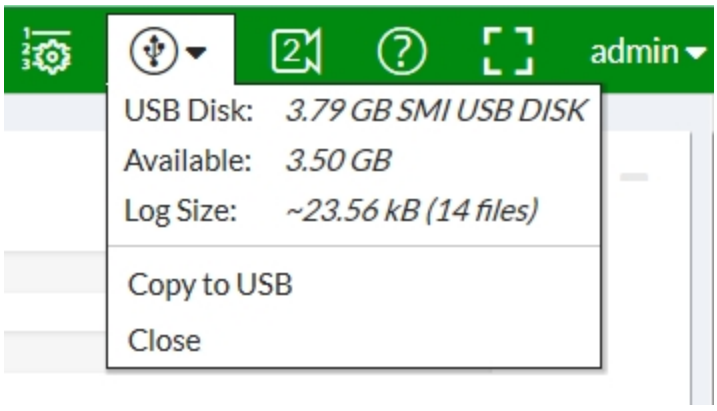
IPS logging optimization (254954)

The handling of IPS logs has been improved. No changes needed, just increased performance on the backend.

Export log messages to USB drive (258913 267501)

Logs can now be exported to a USB storage device, as Lz4 compressed files, from both CLI and GUI.

When you insert a USB drive into the FortiGate's USB port the USB menu appears on the GUI. The menu shows the amount of storage on the USB disk and the log file size and includes a **Copy to USB** option that you can use to copy the log file to the USB drive.



From the CLI you can use the following command to export all log messages stored in the FortiGate log disk to a USB drive:

```
execute backup disk alllogs usb
```

You can also use the following command to backup just traffic logs to a USB drive:

```
execute backup disk log usb traffic
```

Disable performance status logging by default (253700)

Performance statistic logging is now disabled by default. It can be re-enabled in CLI, to occur every 1-15 minutes (enter 0 to disable):

```
config system global
   set sys-perf-log-interval <number from 0-15>
end
```

Add a field for the central NAT id to traffic log messages (257800)

Field name is '*centralnatid*'.

Add http.referrer url to web filter logs (260538)

Field name is '*referralurl*'.

Improve log viewer filters and bottom pane (258873)

The performance status message now shows useful information (254613)

Sample information looks like this, showing percentages and information:

'*Performance statistics: average CPU: 0, memory: 10, concurrent sessions: 8, setup-rate: 0*'

New log message whenever a NAT VDOM is restarted using execute router restart (267562)

Message is '*Router is manually restarted*'.

New GTP logs category (292096)

GTP logs are now handled separately from default Event logs, because of the possible volume of GTP logging.

Maximum values changes

This chapter describes new maximum values changes in FortiOS 5.4.

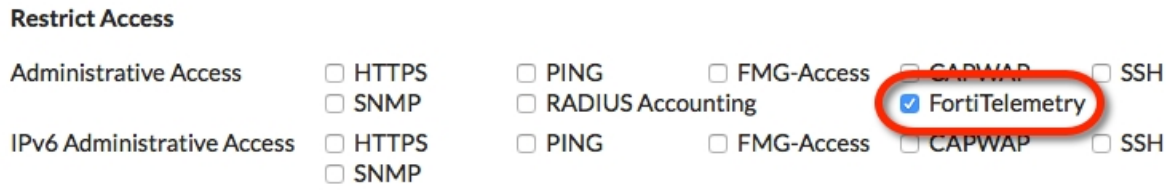
- Increase firewall.policy to 200,000 for 3000 series and above (367574)
- switch-controller.vlan removed from tablesize (370187)
- Changes to VM models max values (307672)
- IPv6 firewall virtual IP-related values changed to match IPv4 firewall virtual IP values. (263999)
- FortiOS Carrier GTP IMSI/APN maximum values increased 50,000 per VDOM. (252723)
- Maximum number of VLANs per interface for the FortiGate/FortiWiFi-30 models increased to 20 VLANs per physical interface. (300032)

Networking

This chapter describes new network features added to FortiOS 5.4.

FortiTelemetry replaces FortiClient Access and other FortiClient interface settings (372945 299371)

To configure an interface to listen for connections from devices with FortiClient installed, enable **FortiTelemetryAdministrative Access**. FortiTelemetry was called FCT-Access or FortiClient Access in FortiOS 5.2.

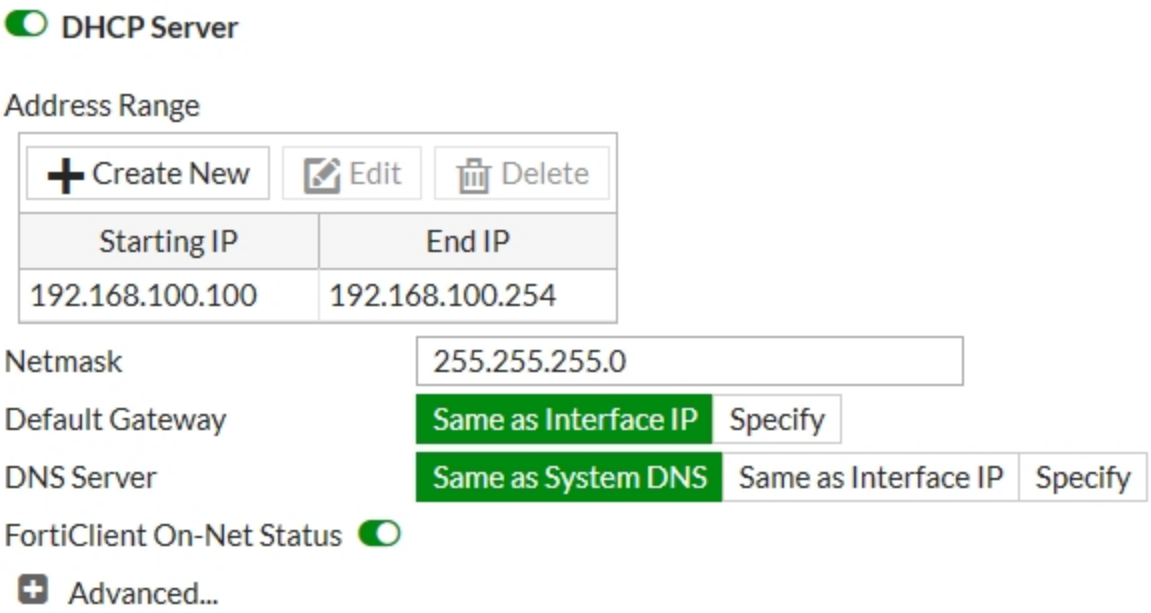


After enabling FortiTelemetry, under **Admission Control** you can select **Enforce FortiTelemetry for all FortiClients** to require clients to have FortiClient installed to be able to get access through the FortiGate. If you enable this feature you should also go to **Security Profiles > FortiClient Profiles** and configure FortiClient Profiles. Then you should add the configured FortiClient Profiles to firewall policies with device detection.

Use the following CLI command to enable FortiHeartBeat on an interface and enable enforcing FortiHeartBeat for all FortiClients:

```
config system interface
   edit port1
      set listen-forticlient-connection enable
      set endpoint-compliance enable
   end
```

After enabling FortiTelemetry, you can also enable **DHCP server** and turn on **FortiClient On-Net Status** to display the on-net status of FortiClient devices on the FortiClient Monitor (go to **Monitor > FortiClient Monitor**).



Use the following CLI command to enable FortiClient on-net status for a DHCP server added to the port1 interface:

```
config system dhcp server
   edit 1
      set interface port1
      set forticlient-on-net-status enable
   end
```

There was a name change involved with this feature. For 5.4.0, it was refered to as FortiHeartBeat, but this only appears in the 5.4.0 GA version of the FortiOS firmware.

TLS support for Dynamic DNS Services (DDNS) (300231)

This feature is available on the FortiGate 140-POE

When clear-text is disable, the FortiGate will use ssl connection to send and receive updates to Dynamic DNS services.

To disable clear-text:

```
config system ddns
   set clear-text disable
   end
```

The ssl-certificate name can also be set in the same location using the command:

```
   set ssl-certificate <cert_name>
```

Defaults:

- clear-text =`enable`
- ssl-certificate = `Fortinet_Factory`

DDNS update override for DHCP (306525 290048)

This feature is available on the FortiGate 140-POE

DHCP server now has an override command option, which allows DHCP server communications to go through DDNS to do updates for the DHCP client.

- This will force a DDNS update of the AA field every time even if the DHCP client does not request it.
- This will allow the support of the allow/ignore/deny client-updates options.

Syntax:

```
config system dhcp server
   edit 0
      set ddns-update_override [enable | disable]
      end
```

disable	Disable DDNS update override for DHCP
enable	Enable DDNS update override for DHCP

Enable or disable individual static and policy routes (174956)

CLI support has been added to [enable | disable] Static and Policy routes.

Syntax for static route in IPv4:

```
config route static
   edit 0
      set status [enable|disable]
      end
```

Syntax for static route in IPv6:

```
config route static6
   edit 0
      set status [enable|disable]
      end
```

Syntax for policy route in IPv4:

```
config router policy
   edit 0
      set status [enable|disable]
      end
```

Syntax for policy route in IPv6:

```
config router policy6
   edit 0
      set status [enable|disable]
      end
```

New option to allow copying of DSCP value in GRE tunnels (306331)

DSCP stands for the Differentiated services code point found in IPv4 and IPv6 headers, used for classifying and managing network traffic such as it relates to Quality of Service. This feature enables the keeping of the DSCP marking in the packets after encapsulation for going through GRE tunnels.

New DHCPv6 Prefix hint feature (302304)

This feature is used to "hint" to upstream DCHPv6 servers a desired prefix length for their subnet to be assigned in response to its request.

There is a possibility of duplicate prefixes being sent by ISP when using a /64 bit subnet because the first 64 bits of the address are derived from the mac address of the interface. This could cause an issue if the system administrator wishes to divide the host networks into 2 /64 bit subnets.

By receiving a /60 bit (for example) network address, the administrator can then divide the internal host works without the danger of creating duplicate subnets.

Also included in the new feature are preferred times for the life and valid life of the DHCP lease.

DHCPv6 hint for the prefix length

`set dhcp6-prefix-hint` <DHCPv6 prefix that will be used as a hint to the upstream DHCPv6 server>

DHCPv6 hint for the preferred life time.

`set dhcp6-prefix-hint-plt` <integer> 1 ~ 4294967295 seconds or "0" for unlimited lease time

DHCPv6 hint for the valid life time.

`set dhcp6-prefix-hint-vlt` <integer> 1 ~ 4294967295 seconds or "0" for unlimited lease tim

The FortiOS DHCP server now has an increased number of DHCP option fields (307342)

In place of specific fields the DHCP server now maintains a table for the potential options. The FortiOS DHCP server supports upto a maximum of 30 custom options.These optional fields are set in the CLI.

To get to the DHCP server:

```
config system dhcp server
   edit <integer - ID of the specific DHCP server>
```

To configure the options:

```
      config options
```

Once in the options context, a few new configuration commands are available. First create an ID for the table entry:

```
edit <integer>
   set code <integer between 0 - 4294967295 to determine the DHCP option>
   set type [ hex | string | ip ]
   set value <option content for DHCP option types hex and string>
   set ip <option content for DHCP option type ip>
end
```

New option to dedicate a FortiGate interface to connect to a managed FortiSwitch (294607)

When setting up an interface, an additional option has been added to the potential addressing modes that dedicates the interface to being the connection to a FortiSwitch.This is covered in more detail in the FortiSwitch section.

New CLI option to change the maximum number of IP route cache entries (363410)

The maximum number of route cache entries is configurable.

Syntax:

```
config system global
   set max-route-cache-size <integer between 0 - 2147483647>
   end
```

Unsetting the field will cause the value to be set to the kernel calculated default.

```
config system global
   unset max-route-cache-size
   end
```

Support for 802.1x fallback and 802.1x dynamic VLANs (308012)

There are 4 modes when enabling 802.1x on a virtual switch interface:

Default	In this mode, it works as it did previously.
Fallback	In fallback mode, the virtual switch will be treated as a master. Only one slave can refer to a fallback master. Those ports in the master virtual switch are always authorized. After passing 802.1x authentication, the ports will be stay authorized and moved to its slave virtual switch.
Dynamic-vlan	In dynamic-vlan mode, the virtual switch will also be treated as a master. However, many slaves can refer to a dynamic-vlan master. Those ports in the master virtual switch are always un-authorized. After passing 802.1x/MAB authentication, the ports will be set to authorized and moved to one of its slave virtual switches.
Slave	In slave mode, a master must be set through security-8021x-master attribute. A slave virtual switch will use its master virtual switch's security-groups settings for authentication.

CLI example for fallback mode

```
config system virtual-switch
   edit "fallsw"
      set physical-switch "sw0"
      config port
   end
   edit "trust"
      set physical-switch "sw0"
   end
config system interface
   edit "fallsw"
      set vdom "root"
      set ip 192.168.20.1 255.255.255.0
      set allowaccess ping https ssh snmp http telnet fgfm auto-ipsec radius-acct probe-
          response capwap
      set type hard-switch
      set security-mode 802.1X
      set security-8021x-mode fallback(fallback mode master switch)
      set security-groups "rds-grp"(the usergroup for 802.1x)
      set snmp-index 10
      next
   edit "trust"
      set vdom "root"
      set ip 192.168.22.1 255.255.255.0
```

```
      set allowaccess ping https ssh snmp http telnet fgfm auto-ipsec radius-acct probe-
          response
      set type hard-switch
      set security-mode 802.1X
      set security-8021x-mode slave(slave mode switch)
      set security-8021x-master "fallsw" (its master switch)
      set snmp-index 6
      next
   end
```

CLI example for dynamic-vlan mode

```
config system virtual-switch
   edit "internal"
      set physical-switch "sw0"
   edit "lan-trust"
      set physical-switch "sw0"
      next
   edit "lan-vlan1000"
      set physical-switch "sw0"
      next
   edit "lan-vlan2000"
      set physical-switch "sw0"
      config port
      edit "internal1" (normally we should not add port in slave switch. This is used if
          user wants to manually add one port in slave)
      end
   end
config system interface
   edit "internal"
      set vdom "root"
      set ip 192.168.11.99 255.255.255.0
      set allowaccess ping https ssh http fgfm capwap
      set type hard-switch
      set security-mode 802.1X
      set security-8021x-mode dynamic-vlan<------dynamic-vlan mode master switch
      set security-groups "rds-grp"<------the usergroup for 802.1x
      set snmp-index 15
      next
   edit "lan-trust"
      set vdom "root"
      set ip 192.168.111.99 255.255.255.0
      set allowaccess ping https ssh snmp http telnet fgfm auto-ipsec radius-acct probe-
          response capwap
      set type hard-switch
      set security-mode 802.1X
      set security-8021x-mode slave<-----slave mode switch
      set security-8021x-master "internal"<-----its master switch
      set snmp-index 7
      next
   edit "lan-vlan1000"
      set vdom "root"
      set ip 192.168.110.1 255.255.255.0
      set allowaccess ping https ssh snmp http telnet fgfm auto-ipsec radius-acct probe-
          response capwap
      set type hard-switch
      set security-mode 802.1X
      set security-8021x-mode slave<-----slave mode switch
```

```
    set security-8021x-master "internal"<-----its master switch
    set security-8021x-dynamic-vlan-id 1000 <-----the matching vlan id for this virtual
        switch
    set snmp-index 16
    next
  edit "lan-vlan2000"
    set vdom "root"
    set ip 192.168.220.1 255.255.255.0
    set allowaccess ping https ssh snmp http telnet fgfm auto-ipsec radius-acct probe-
        response capwap
    set type hard-switch
    set security-mode 802.1X
    set security-8021x-mode slave
    set security-8021x-master "internal"
    set security-8021x-dynamic-vlan-id 2000
    set snmp-index 17
    end
  config user group
    edit "rds-grp"
      set dynamic-vlan-id 4000(default vlan id if there is no vlan attribute return
          from server)
      set member "190"
    end
```

Internet-Service database (288672 281333 291858)

Go to ***Policy & Objects > Internet Service Database*** to view the Internet Service Database. The database contains detailed information about services available on the Internet such as DNS servers provided by Adobe, Google, Fortinet, Apple and so on and a wide range of other services. For each service the database includes the IP addresses of the servers that host the service as well as the port and protocol number used by each IP address.

Interfaces assigned to Virtual Wired Pairs don't have "roles" (296519)

Assigning an interface to be part of a virtual wire pairing will remove the "role" value from the interface.

STP (Spanning Tree Protocol) support for models with hardware switches (214901 291953)

STP used to be only available on the old style switch mode for the internal ports. It is now possible to activate STP on the hardware switches found in the newer models. These models use a virtual switch to simulate the old Switch Mode for the Internal ports.

The syntax for enabling STP is as follows:

```
config system interface
  edit lan
  set stp [enable | disable]
  end
```

Command to determine interface transceiver optical signal strength (205138 282307)

The new `get system interface transceiver` command can be used to determine optical signal strength when using SFP/SFP+ modules. The command can be used for trouble shooting fiber optic connections to service providers. This command is hardware dependent and currently supported by FortiGate models that

include various SFP/SFP+ interfaces including the FortiGate-100D/200D-POE/400D/500D/900D/1000D/1200D/1500D/3700D/3700DX) models.

New command to get IPv6 multicast router information (267650)

The following command displays IPv6 multicast router information just like the IPv4 version of the command.

```
get router info6 multicast.
```

FortiGate DHCP works with DDNS to allow FQDN connectivity to leased IPs (267043)

As clients are assigned IP addresses, they send back information that would be found in an A record to the FortiGate's DHCP server, which can take this information and passes it back to a corporate DNS server so that even devices using leased IP address can be reached using FQDNs. The settings for this feature are configured through the CLI using the ddns-update command and some other ddns related options.

Fortinet's Dynamic DNS services (FortiDDNS) can be registered to a public IP address (251748)

Fortinet's Dynamic DNS services (FortiDDNS) can be registered to a public IP address even if the FortiGate itself does not have any physical interfaces on the Internet. This is applicable when the FortiGate is behind other networking devices that are employing NAT. This can be configured in the GUI as well as CLI.

Can use firewall addresses for static route destinations (273672)

To help prevent false positive when scanning for duplicate static routes, the dst_addr field is also checked.

Can use firewall addresses for policy route destinations (244101)

When configuring a policy route, firewall addresses and address groups can be used. The only exception for address types that can be used is the URL type of address object.

Enhance TWAMP Light functionality with server/controller functionality (249255)

TWAMP(Two-Way Active Measurement Protocol) Light is a simplified architecture within the TWAMP standard. Its purpose is to measure the round trip IP performance between any two devices within a network that supports the protocol. Now FortiOS operates in more than just the role of responder/reflector.The server/controller functionality has been added.

More information about interface status available from GUI (240285)

The following information is added to the 'hover' details for each port on the GUI FortiGate faceplate:

- MAC address
- Tx/Rx bytes
- Tx/Rx packets
- Tx/Rx errors

In addition, optional columns are added to the interface list to allow users to see all of the above information.

Virtual WAN link fixes (255122)

The firmware now has the following fixes or improvements to Virtual WAN links (VWL):

- Better support for dynamic interfaces (PPPoE and DHCP).
  - It can remove dynamically added routes, and restore these routes once the interfaces are not members.
  - It can count pppoe interface sessions.
  - It can generate a proute for a PPPoE interface. In this proute, the gateway is specified, while the outgoing (PPPoE)interface will not set.
- Adjust the route policy for a manual mode VWL service
- Support HTTP monitor by version 1.1, which obsoletes version 1.0's behavior.
- Apply multiple dst and src new feature for one policy to VWL.
- Improvements to CLI usability:
  - It hides interfaces that are being used in a policy or a zone
  - There is a check when adding an interface to a static route. This check will raise an error if the interface is a member of a VWL.
  - Updates a proute, if based on config change, if the associated link-monitor dies.
  - Fix some inappropriate messages.
  - Revised the minimum value of interval for a link-monitor object. The new value is 1, so it can be compatible with V5.0. When the timeout is 1, and interval is 1.

Router > Static > Settings GUI options available from the CLI only

As part of the new WAN Load Balancing feature, the FortiOS 5.2 **Router > Static > Settings** GUI page has been removed. WAN Load Balancing should be used instead of the 5.2 **ECMP Load Balancing Method** settings. The 5.2 **Link Health Monitor** definitions are now only available from the CLI.

Ports preassigned as sniffer ports by default (261921)

Some models of FortiGate, by default have ports preconfigured as sniffer ports.

The models and ports preconfigered in sniffer mode are as follows:

- FortiGate 300D
  - Port4
  - Port8
- FortiGate 500D
  - Port5
  - Port6
  - Port13
  - Port14

Enable or disable inspecting IPv4 and IPv6 ICMP traffic (258734)

In order for the inspection of assymetric ICMP traffic to not affect TCP and UDP traffic, a pair of settings have been added that can enable/disable the inspection of ICMP traffic being routed assymetricly for both IPv4 and IPv6.

The syntax in the CLI for configuring the setting is:

- IPv4

```
config system settings
   set asymroute-icmp
   end
```

- IPv6

```
config system settings
   set asymroute6-icmp
   end
```

Send GARP on aggregate MAC change (273363)

FortiGates will send out GARP (Gratuitous Address Resolution Protocol) announcements if the MAC address of a link aggregated interface has changed to a new IP pool address due to a link failure or change in ports. This is needed when using networking devices, such as some switches, that don't perform this function when they receive LACP (Link Aggregation Control Protocol) information about changes in the MAC information.

Support split ports (252444)

The 5001D 40 GB can be split into 4 10 GB ports.This is done through a combination of hardware and software configuration. A specific 40 GB connector is used to connect to the 40 GB port and normally, the other end of the fibre optic cable would connect to another 40 GB port but a special cable can be used that is a single 40 GB connector at one end and 4 10 GB connections at the other. To use this set up the port also has to be configured to be a split port.

The configuration option can be found in the CLI:

```
config system global
   set port-split port1 port2
   end
```

The ports will be checked to make sure that they are not in use or referenced by other policy configurations. If in use the command will be aborted. Changing the port to be a split port will require a system reboot.

Add FortiClient enforcement to interfaces (253933)

The use of FortiClient can be enforced on individual interfaces. Go to **Network > Interfaces** and pick the interface of your choice. Under the heading **Admission Control**, you can enable the setting **Allow FortiClient Connections**.Once this setting is enabled, two more options become visible, **Discover Clients (Broadcast)** and **FortiClient Enforcement**. By enabling FortiClient Enforcement you enforce that in order for incoming traffic to pass through that interface it must be initiated by a device running FortiClient.

Once the use of FortiClient is enforced on the interface, FortiClient profiles should also be configured for the incoming connections. You can also set up any exemptions that are needed. Just below the **FortiClient Enforcement** option are fields for **Exempt Sources** and **Exempt Destinations/Services**. These can be selected from address or services object already configured on the FortiGate.

In the CLI the enforcement can be set up as follows:

```
config system interface
   edit port1
      set listen-forticlient-connection [enable|disable]
      set endpoint-compliance [enable|disable]
      end
```

Botnet C&C protection added to interfaces (254959)

The function of Botnet and Command & Control traffic protection is not new but how it can be configured has changed. It is no longer part of the AntiVirus Security profile.

The option to **ScanOutgoing Connections to Botnet Sites** has been added to the Interface page in the GUI.

The options are **Disable**, **Block** and **Monitor.**

In the CLI, the botnet scan can be configured on the interface by entering the following commands:

```
config system interface
   edit <interface>
      set scan-botnet-connections [disable | block | monitor]
      end
```

It is also possible to enable the scanning of botnet and C&C traffic in

- Firewall policies

```
config firewall policy
   edit <policyid>
      set scan-botnet-connections [disable | block | monitor]
      end
```

- Firewall explicit proxy policies

```
config firewall explicit-proxy-policy
   edit <policyid>
      set scan-botnet-connections [disable | block | monitor]
      end
```

- Firewall interface policy

```
config firewall interface-policy
   edit <policyid>
      set scan-botnet-connections [disable | block | monitor]
      end
```

- Firewall sniffer

```
config firewall sniffer
   edit <policyid>
      set scan-botnet-connections [disable | block | monitor]
      end
```

Netflow 9.0 support (167405)

Netflow is a networking feature introduced by Cisco to collect and export information about traffic flow through routers. IPFIX (Internet Protocol Flow Information Export) is the standardized Internet Protocol based on NetFlow version 9. The standards requirements for IPFIX are outlined in RFC 3197 and its basic specifications and other information are documented in RFC 5103, RFC 6759 and RFC 7011 through RFC 7015.

The CLI changes that enable and configure "NetFlow" traffic are:

```
config system netflow
   set collector-ip <collector IP>
   set collector-port <NetFlow collector port>
   set csource-ip <Source IP for NetFlow agent>
   set cactive-flow-timeout <time in minutes of timeout to report active flows>
   set cinactive-flow-timeout <time in seconds of timeout for periodic report of finished
       flows>
   end
```

These setting can also be configured per VDOM by going to:

```
config system vdom-netflow
```

A Netflow sampler will also have to be enabled on specific interfaces.

IPv6 blackhole static routing (220101)

System administrators use black hole routing to divert undesirable traffic, such as packets from a Denial of Service (DoS) attack or communications from an illegal source. The traffic is routed to a dead interface, or a host designed to collect information for investigation. This mitigates the impact of the attack on the network.

The use of blackhole routing is enabled in the CLI as follows:

```
config router static6
   edit <ID #>
      set blackhole enable
   end
```

A collection of Routing changes (261043)

A few new settings have been added to the CLI to assist in the supporting of the IPsec Auto Discovery feature. They are designed for:

- The support of the RIPng (RIP next generation) network command
- Limiting the maximum metric allowed to output for RIPng
- Fix NSM missing kernel address update info

The actual new settings are:

```
config router rip
   set max-out-metric <integer value 1 - 15>
   end

config router ripng
   set max-out-metric <integer value 1 - 15>
   end

config router ripng
   config network
      edit <ID # of network>
         set prefix <IPv6 prefix>
         end
      end
```

DHCPv6 prefix delegation (266061)

Prefix delegation is now support for DHCP for IPv6 addressing. It is not practical to manually provision networks on a large scale in IPv6 networking. The DHCPv6 prefix delegation feature is used to assign a network address prefix, and automate the configuration and provisioning of the public routable addresses for the network.

Enabling the prefix delegation is done only in the CLI as in the following example:

```
config system interface
   edit "wan1"
      config ipv6
         set ip6-mode dhcp
         set ip6-allowaccess ping
         set dhcp6-prefix-delegation enable
         end
      end
```

Proxy-arp extensions (250651)

The proxy-arp configuration can be extendend to an IP address range rather than a single IP address. A new setting has been added to the CLI. When configuring the proxy-arp, in addtion to setting the IP address, an end-ip address can also be set. If it is not set, the proxy-arp will be a single address as before. An example configuration using the new setting would be a follows:

```
config system proxy-arp
   edit 1
      set interface "internal"
      set ip 192.168.1.100
      set end-ip 192.168.1.102
      end
```

Routing

Add asymmetric route for icmp/icmp6:

Adding asymmetric route for icmp/icmp6 without effecting tcp/udp.

Enhance TWAMP Light functionality with server/controller functionality

Add support for twamp lite mode for both controller and responder site.

CLI changes:

Add twamp protocol as a probe protocol in the link-monitor CLI.

```
config vdom
   edit root
      config system link-monitor
         edit lnkmt1
            set protocol twamp //TWAMP link monitor.
         end
      end
```

Route Lookup

Route Lookup is under **Router > Monitor > Routing Monitor**, the input criteria are **Destination IP address/FQDN**, and an enable check box for **IPv6**.

After clicking on **Search** button, the trace result will be selected on routing monitor page with highlight.

RFCs supported by FortiOS 5.4

The following RFCs are now supported by FortiOS 5.4:

RFC 2231 MIME Parameter Value and Encoded Word Extensions: Character Sets, Languages, and Continuations (280039)

RFC 7507 TLS Fallback Signaling Cipher Suite Value (SCSV) for Preventing Protocol Downgrade Attacks (308040)

Improve support for RFC 2516 A Method for Transmitting PPP Over Ethernet (PPPoE) (213945)

RFC 4106 The Use of Galois/Counter Mode (GCM) in IPsec Encapsulating Security Payload (ESP)

RFC 4303 IP Encapsulating Security Payload (ESP) (255144)

RFC 4304 Extended Sequence Number (ESN) Addendum to IPsec Domain of Interpretation (DOI) for Internet Security Association and Key Management Protocol (ISAKMP)

RFC 4478 Repeated Authentication in Internet Key Exchange (IKEv2) Protocol (282025)

RFC 4754 IKE and IKEv2 Authentication Using the Elliptic Curve Digital Signature Algorithm (ECDSA) (0206110)

RFC 5176 Dynamic Authorization Extensions to Remote Authentication Dial In User Service (RADIUS) (239028)

RFC 5177 Network Mobility (NEMO) Extensions for Mobile IPv4 (249570)

RFC 5723 Internet Key Exchange Protocol Version 2 (IKEv2) Session Resumption (289914)

RFC 5996 Internet Key Exchange Protocol Version 2 (IKEv2) (255144)

RFC 6106 IPv6 Router Advertisement Options for DNS Configuration (266061)

RFC 6290 A Quick Crash Detection Method for the Internet Key Exchange Protocol (IKE) (298970)

RFC 6888 Common Requirements for Carrier-Grade NATs (CGNs)

RFC 7539 ChaCha20 and Poly1305 for IETF Protocols (264785)

RFC 4787 Network Address Translation (NAT) Behavioral Requirements for Unicast UDP (229074)

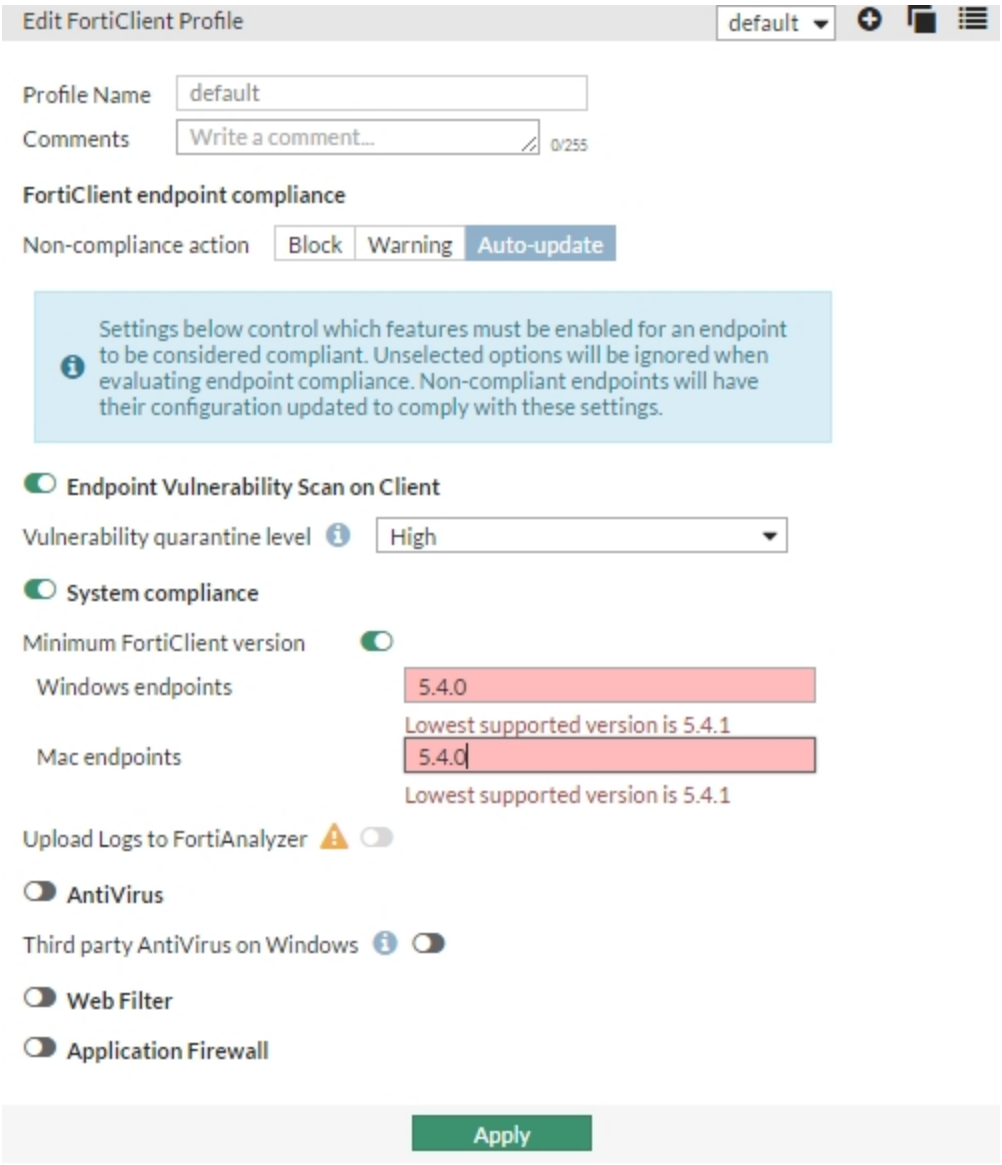
Security Profiles

This chapter describes new security profile features added to FortiOS 5.4.

FortiClient Profile changes (356205)

Features involving general settings have been removed from the FortiClient profile GUI in 5.4.1. Features emphasizing compliance of the endpoint devices have been added. These enhancements facilitate integration with the Cooperative Security Fabric.

When FortiClient endpoint compliance is enabled and FortiClient endpoints are registered to FortiGate, you must upgrade registered FortiClient endpoints. Be sure to upgrade registered endpoints to FortiClient 5.4.1 before upgrading your FortiGate to FortiOS 5.4.1.



FortiClient endpoint compliance enforcement has three actions. When the action is set to **Block** or **Warning**, it is up to you to provision endpoints either via the Enterprise Management Server (EMS) or manually. When the action is set to **Auto-update**, the FortiGate will provision the endpoint.

Action	Meaning
Block	If the endpoint does not match compliance rules in the FortiClient Security Profile, then it will be blocked.
Warning	If the endpoint does not match compliance rules in the FortiClient Security Profile, then it will show on the Monitor > FortiClient Monitor as not-compliant. Traffic will not be blocked.
Auto-update	If the endpoint is not-compliant, the FortiGate will push a limited profile to the endpoint and attempt to get it to be compliant.

CLI syntax

A third value called **compliant** and new attributes have been added to existing CLI.

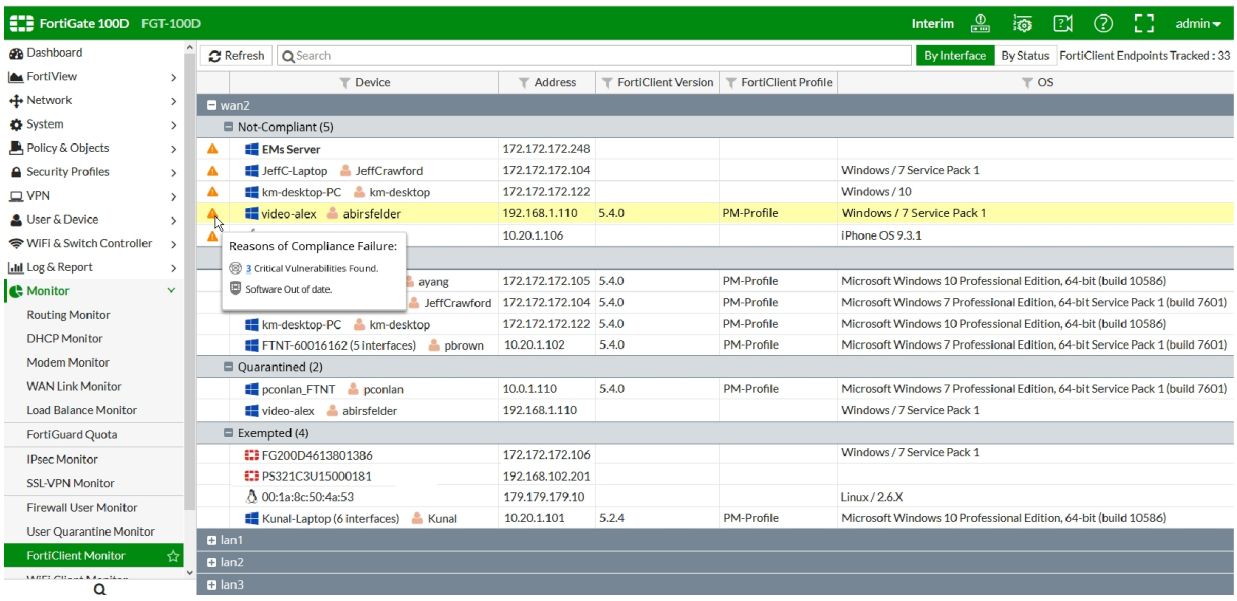
```
config endpoint-control profile
   edit <profile name>
      config forticlient-winmac-settings
         set compliance-action {block | warning | auto-update}
         set os-av-software-installed {enable | disable}
         set forticlient-log-upload-level {traffic | vulnerability | event}
         set forticlient-system-compliance {enable | disable}
         set forticlient-minimum-software-version {enable | disable}
         set forticlient-vuln-scan-enforce {enable | disable}
         set forticlient-vuln-scan-enforce-grace {0 - 30 days, default = 1}
         set sandbox-analysis {enable | disable}
      end
   end
```

FortiClient Monitor page updates (304254)

Updates to the **Monitor** page allow the user to view FortiClient endpoint devices grouped by interface and then sub-grouped by compliance status. Compliance status can be compliant, non-compliant, exempt, or quarantined.

	FortiClient Enforcement	
Status	**Enabled**	**Disabled**
Compliant	List only active FortiClientEndpoints.	No devices listed
Not-compliant	List devices not-compliant with FortiClient profile, so long as they are not exempt.	No devices listed
Exempt	List FortiClient endpoints exempt from FortiClient compliance.	List of all user devices except those quarantined by the administrator.
Quarantined	List devices quarantined by the administrator.	List devices quarantined by the administrator.

You can see the reasons for non-compliance by right-clicking on an endpoint in the list.



FortiClient Endpoint Control Profile Attributes (306833)

Certain attributes have been removed from, added to, or changed in the FortiClient endpoint control profile configuration.

Attributes Removed

You can no longer configure these attributes in the FortiClient endpoint control profile:

```
view-profile-details
scan-download-file
wait-sandbox-result
use-sandbox-signature
block-malicious-website
block-attack-channel
av-scheduled-scan
av-scan-type
av-scan-schedule
av-scan-time
av-scan-exclusions
monitor-unknown-application
install-ca-certificate
disable-wf-when-protected
forticlient-vuln-scan-schedule
forticlient-vuln-scan-on-registration
forticlient-vpn-provisioning
forticlient-advanced-vpn
forticlient-advanced-vpn-buffer
disable-unregister-option
forticlient-log-ssl-upload
forticlient-log-upload-schedule
forticlient-update-from-fmg
forticlient-update-server
forticlient-update-failover-to-fdn
forticlient-settings-lock
forticlient-settings-lock-passwd
```

```
   auto-vpn-when-off-net
   auto-vpn-name
   client-log-when-on-net
   forticlient-ad
   fsso-ma
   fsso-ma-server
   fsso-ma-psk
   allow-personal-vpn
   disable-user-disconnect
   vpn-before-logon
   vpn-captive-portal
   forticlient-ui-options
   forticlient-advanced-cfg
   forticlient-advanced-cfg-buffer
```

Attributes Added

The following attributes have been added to the FortiClient endpoint control profile configuration.

```
config endpoint-control profile
   edit <profile_name>
   config forticlient-winmac-settings
      set sandbox-analysis {enable | disable}
      set compliance-action {block | warning | auto-update}
      set os-av-software-installed {enable | disable}
      set forticlient-minimum-software-version {enable | disable}
      set forticlient av {enable | disable}
      set forticlient-system-compliance {enable | disable}
      set forticlient-log-upload
      set forticlient-log-upload-level {traffic |vulnerability | event}
      set forticlient-vuln-scan-enforce {enable | disable}
      set forticlient-vuln-scan-enforce-grace {number}
   end
end
```

Attributes Changed

There is a change to the CLI commands to enable or disable the sending of files to FortiSandbox for analysis.

The CLI command:

```
config endpoint-control profile
   edit <name_str>
   config forticlient-winmac-settings
      edit <name_str>
         set sandbox-scan {enable | disable}
      end
   end
```

has been replaced by:

```
config endpoint-control profile
   edit <name_str>
   config forticlient-winmac-settings
      edit <name_str>
         set sandbox-analysis {enable | disable}
```

```
    end
  end
```

Optionally include FortiGuard spam responses in email log messages (284055)

The field **FortiGuard Spam Response** has been added as an option to the anti-spam log to aid in identifying misclassified email.

Virus scanning of MS Outlook email (308797)

FortiOS 5.4.1 allows users to enable or disable inspection of MAPI-over-HTTP (MAPI/HTTP) protocol. This protocol was first delivered with Outlook 2013 SP1 and Exchange 2013 SP1. Enabling inspection ensures that the FortiGate can scan Outlook email for viruses.

CLI commands

```
config firewall ssl-ssh-profile
   edit deep-inspection
   set mapi-over-https {enable|disable}
```

Improved Visibility of Botnet and Command & Control (C&C) protection (308104)

Mobile & Botnet C&C license information is now displayed in the License Information widget in the Dashboard. Additionally, you can view the list of Botnet C&C packages in the IP Reputation Database (IRDB) and the Botnet Domain Database (BDDB) from the License Information widget.

A button has been added to the GUI on the DNS filter page allowing you to block DNS requests known to FortiGuard. When you enable this feature, you can open a definitions window by clicking on "botnet package."

Access to the IRDB is available to users through FortiCare support contracts purchased or renewed before October 1, 2016. After that date, users will have to subscribe to the IRDB either through the FortiGuard Mobility Security Service (FMSS) or the FortiGuard Enterprise Bundle.

DLP changes (297960)

Some DLP features removed. DLP fingerprinting removed from the GUI.

FortiClient Endpoint Profile improvements and new features (285443 275781 287137)

- **275781:** New options available in **FortiClient Profiles**.
- **285446:** VPN can be configured on the GUI either on **IPsec VPN** or **SSL-VPN** and changes can be preserved.
- **287137:** In the **Mobile** tab, .mobileconfig files can be configured and **Client VPN Provisioning** can be enabled.

Features involving general settings have been removed from the FortiClient profile GUI in 5.4.1. Features emphasizing compliance of the endpoint devices have been added. Read FortiClient Profile changes for more information.

FortiClient Enforcement added to Interfaces (253933)

FortiClient enforcement has been moved from the Policy page to **Network > Interfaces** to enforce FortiClient registration on a desired LAN interface rather than a policy.

To enforce FortiClient endpoint registration - GUI:

1. Go to **System > Feature Select** and enable **Endpoint Control**.
2. Go to **Network > Interfaces** and select the internal interface.
3. Under **Restrict Access**, enable **FortiTelemetry**.
4. Under **Admission Control**, enable **Enforce FortiTelemetry for all FortiClients**.

FortiClient exempt list improvements (268357 293191)

- **268357:** Before you could only configure captive portal policy addresses in the CLI, but it can now be performed in the GUI.
- **293191: Exempt List** has been replaced with **Exempt Sources**, and **Exempt Destinations/Services** has been added (once an interface has been set to captive portal). Before it was only possible to configure the FortiGate interface port to captive portal through the CLI, but it can now also be performed in the GUI.

FortiClient endpoint profile page updates (283968)

The **Security Profiles > FortiClient Profiles** page has been redesigned to better present the information available, and so the user can easily locate particular settings of interest.

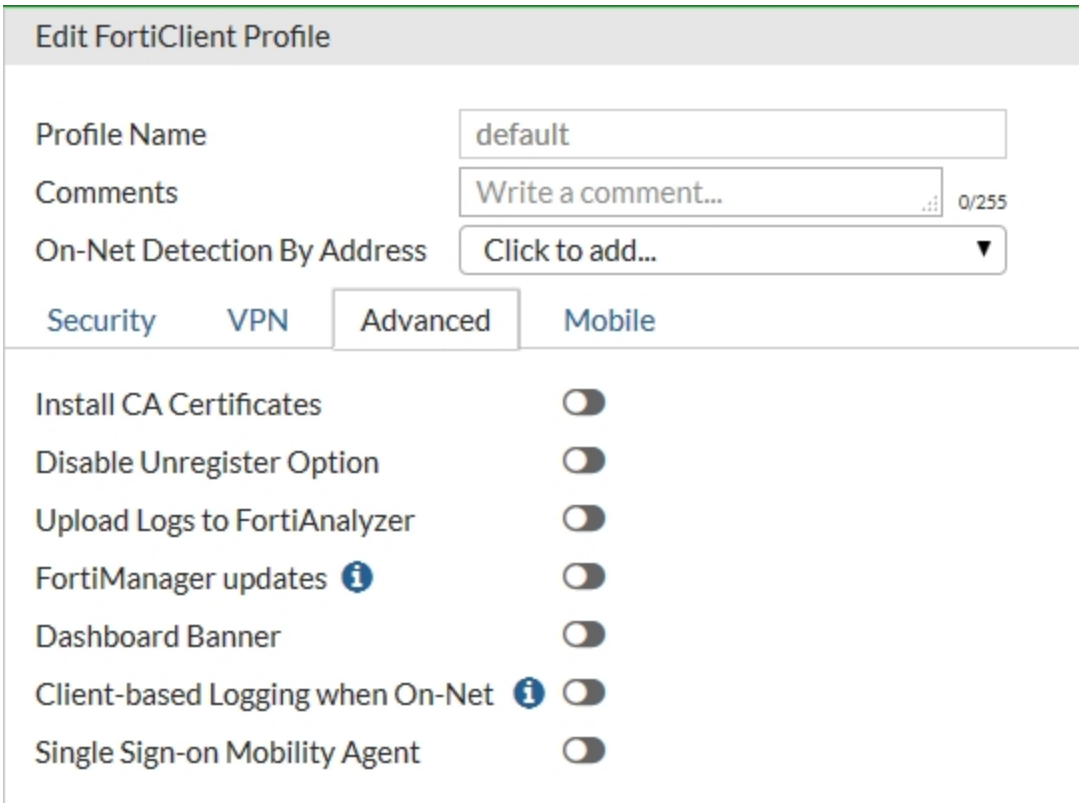
Pre-existing GUI options under **User & Device > FortiClient Profiles** have been moved to the **Security Profiles** menu, and have been reorganized into separate tabs: **Security**, **VPN**, **Advanced**, and **Mobile**. Profiles can be created and options can be enabled within these tabs.

The **VPN**, **Advanced**, and **Mobile** tabs do not appear in the GUI in FortiOS5.4.1. See FortiClient Profile changes (356205).

Note that **Client-based Logging when On-Net** has been renamed to **Allow Access to Logs from FortiClient Console**.

In addition, the following features were added:

- Support for FortiSandbox integration
- Option for C&C destination scanning and blocking
- Certificate deployment as part of endpoint profile
- FortiClientRTP Option updates
- Option to monitor all unknown applications



Configure the ability to store FortiClient configuration files (171380)

1. Enable the advanced FortiClient configuration option in the endpoint profile:

```
config endpoint-control profile
   edit "default"
      set forticlient-config-deployment enable
      set fct-advanced-cfg enable
      set fct-advanced-cfg-buffer "hello"
      set forticlient-license-timeout 1
      set netscan-discover-hosts enable
   next
end
```

2. Export the configuration from FortiClient (xml format).
3. Copy the contents of the configuration file and try to paste in the advanced FortiClient configuration box.

If the configuration file is greater than 32k, you need to use the following CLI:

```
config endpoint-control profile
   edit <profile>
      config forticlient-winmac-settings
         config extra-buffer-entries
            edit <entry_id>
               set buffer xxxxxx
            next
         end
      end
   end
```

FortiOS 5.4 no longer supports FortiClient 5.0 or earlier (289455)

FortiOS 5.2 would support FortiClient 5.0 (only if the FortiGate upgraded to FortiOS 5.2), however FortiOS 5.4 will no longer support FortiClient 5.0. Customers need to purchase a FortiClient 5.4 subscription-based FortiClient license.

Session timers for IPS sessions (174696 163930)

The standard FortiOS session time-to-live (session TTL) timer for IPS sessions has been introduced to reduce synchronization problems between the FortiOS Kernel and IPS. This has been added so that FortiGate hard-coded timeout values can be customized, and IPS was using too much overall memory.

Botnet protection with DNS Filter (293259)

The new botnet list from FortiGuard can be used to block DNS requests to known botnet C&C IP addresses within a new DNS filter profile.

You can view the botnet list by going to **System > FortiGuard > Botnet Definitions**.

Secure white list database (288365)

Secure white list exemption for SSL deep inspection. To enable, go to **Security Profiles > SSL/SSH Inspection** and enable **Exempt from SSL Inspection** and enable **Reputable Websites**.

Mobile Malware protection update (288022)

Mobile Malware protection requires a separate license and can be downloaded as a separate object. The mobile malware signatures are no longer part of the AntiVirus Database but these signatures can be enabled by going to **Security Profiles > AntiVirus** and enabling **Include Mobile Malware Protection**.

Options not supported by the new quick mode flow-based virus scanning (288317)

Files cannot be sent to FortiSandbox for inspection while in quick mode flow-based virus scanning, and so the GUI option for it has been removed. No option to switch between quick mode and full mode, as choice between **Proxy** and **Flow** based inspection has been removed.

Add mobile malware to FortiGuard licenses page and include more version information (290049)

An entry and version information for **Mobile Malware Definitions** has been added in the **License Information** table under **System > FortiGuard**. Also, main items have been bolded and sub-items have been indented for clarification.

Secure white-list DB for flow based UTM features (287343)

A new feature that gathers a list of reputable domain names that can be excluded from SSL deep inspection. This list is periodically updated and downloaded to FortiGate units through FortiGuard.

Syntax:

```
config firewall ssl-ssh-profile
   edit deep-inspection
      set whitelist enable
end
```

New customizable replacement message that appears when an IPS sensor blocks traffic (240081)

A new replacement message will appear specifically for IPS sensor blocked Internet access, to differentiate between IPS sensor blocking and application control blocking.

Low-end models don't support flow AV quick mode and don't support the IPS block-malicious-url option (288318)

AV quick mode and the IPS block-malicious-url option have been disabled on low-end FortiGate models, however these features can be enabled if the FortiGate unit has a hard disk. Low-end models will only support**Full**scan mode (the option is left in the GUI to show which mode is active for the user).

New quick mode flow-based virus scanning (281291)

When configuring flow-based virus scanning you can now choose between quick and full mode. Full mode is the same as flow-based scanning in FortiOS 5.2. Quick mode uses a compact antivirus database and advanced techniques to improve performance. Use the following command to enable quick mode in an antivirus profile:

```
config antivirus profile
   edit <profile-name>
      set scan-mode {quick | full}
   end
```

CVE-IDs now appear in the FortiOS IPS signature list (272251)

The signature list can be found at **Security Profiles > Intrusion Protection > View IPS Signatures**.

Botnet protection added (254959)

The latest Botnet database is available from FortiGuard. You can see the version of the database and display its contents from the **System > FortiGuard** GUI page. You can also block, monitor or allow outgoing connections to Botnet sites for each FortiGate interface.

FortiSandbox URL database added

You can see the version of the database and display its contents from the **System > FortiSandbox** GUI page.

New Web Filter profile whitelist setting and changes to blacklist setting (283855, 285216)

Domain reputation can now be determined by "common sense", for sites such as Google, Apple, and even sites that may contain sensitive material that would otherwise be trusted (i.e. there is no risk of receiving botnets or malicious attacks). You can tag URL groups with flags that exempt them from further sandboxing or AV analyzing.

You can identify reputable sites and enable certain bypasses under **Security Profiles > Web Filter**.

Similarly, you can exempt the identified reputable sites from SSL inspection.

CLI Syntax

```
config firewall ssl-ssh-profile
```

```
   edit <profile-name>
      set whitelist [enable | disable]
end

config webfilter profile
   edit <profile-name>
      config web
      set whitelist exempt-av exempt-webcontent exempt-activex-java-cookie exempt-dlp
          exempt-rangeblock extended-log-others
      end
end
```

Support security profile scanning of RPC over HTTP traffic (287508)

This protocol is used by Microsoft Exchange Server so this feature supports security profile features such as virus scanning of Microsoft Exchange Server email that uses RPC over HTTP.

Users now allowed to override blocked categories using simple, wildcard, and regex expressions to identify the URLs that are blocked (270165)

This feature is also called per-user BWL. To be able to configure this feature from the GUI enter the following command:

```
config system global
   set per-user-bwl enable
end
```

Then go to **Security Profiles > Web Filtering**, edit a web filtering profile and select **Allow users to override blocked categories**.

Use the following command to configure this feature from the CLI:

```
config webfilter profile
   edit <profile-name>
      set options per-user-bwl
   end
```

Set flow or proxy mode for your FortiGate (or per VDOM) (266028)

You can configure your FortiGate or a VDOM to apply security profile features in proxy or flow mode. Change between modes from the System Information dashboard widget. Proxy mode offers the most accurate results and the greatest depth of functionality. Flow mode provides enhanced performance. IPS and application control always operates in flow mode and so is not affected by changing this mode.

Security Profiles > Web Application Firewall

Signatures can now be filtered based on risk level.

The options to reset action and apply traffic shaping is now only available in the CLI.

The *All Other Known Applications* option has been removed, while the option for *All Other Unknown Applications* has been renamed *Unknown Applications*.

Block all Windows executable files (.exe) in email attachments (269781)

A new option has been added to AntiVirus profiles to block all Windows executable files (.exe) in email attachments.

CLI Syntax

```
config antivirus profile
   edit "default"
      config imap
         set executables {default | virus}
      end
      config pop3
         set executables {default | virus}
      end
      config smtp
         set executables {default | virus}
      end
      config mapi
         set executables {default | virus}
      end
   end
```

Cookies can now be used to authenticate users when a web filter override is used (275273)

Cookies can be used to authenticate users when a web filter override is used. This feature is available in CLI only.

CLI Syntax

```
config webfilter cookie-ovrd
   set redir-host <name or IP>
   set redir-port <port>
end

config webfilter profile
   edit <name>
      config override
         set ovrd-cookie {allow | deny}
         set ovrd-scope {user | user-group | ip | ask}
         set profile-type {list | radius}
         set ovrd-dur-mode {constant | ask}
         set ovrd-dur <duration>
         set ovrd-user-group <name>
         set profile <name>
      end
   end
```

Blocking malicious URLs (277363)

A local malicious URL database dowloaded from FortiGuard has been added to assist IPS detection for live exploits, such as drive-by attacks. You enable blocking malicious URLs in an IPS profile from the CLI using the

following command:

CLI Syntax

```
config ips sensor
   edit default
      set block-malicious-url {enable | disable}
   next
end
```

The FortiGuard IPS/AV update schedule can be set by time intervals (278772)

This feature allows updates to occur more frequently (syntax below shown for updates randomly every 2-3 hours).

CLI Syntax

```
config system autoupdate schedule
   set frequency every
   set time 02:60
end
```

Application Control signatures belonging to industrial category/group are excluded by default (277668)

Use the following command to be able to add industrial signatures to an application control sensor:

```
config ips global
   set exclude-signatures {none | industrial}
end
```

The Industrial category now appears on the Application Control sensor GUI.

An SSL server table can now be used for SSL offloading (275273)

CLI Syntax

```
config firewall ssl-ssh-profile
   edit <name>
      set use-ssl-server {enable | disable}
   next
end
```

MAPI RPC over HTTP/HTTPS traffic is now supported for security scanning (278012)

CLI Syntax

```
config firewall profile-protocol-options
   edit "default"
      set comment "All default services."
         config http
            set ports 80 3128
            set options rpc-over-http
         end
```

```
    end
```

New Dynamic DNS FortiGuard web filtering sub-category (276495)

A new FortiGuard web filtering sub-category, Dynamic DNS, has been added and can be found in the Security Risk Category. Also, the sub-category *Shopping and Auction* has been separated into two sub-categories: *Auction* and *Shopping.*

New Filter Overrides in the Application Sensor GUI (260901)

The overrides allow you to select groups of applications and override the application signature settings for them.

FortiGate CA certificates installed on managed FortiClients (260902)

This feature allows you to enable or disable CA certificate installation on managed FortiClients in a FortiClient Profile.

Syntax

```
config endpoint-control profile
   edit <profile>
      config forticlient-winmac-settings
         set install-ca-certificate [enable | disable]
      end
   next
end
```

More exemptions to SSL deep inspection (267241)

Some common sense exemptions have been added to the default SSL deep inspection profile, such as Fortinet, Android, Apple, Skype, and many more.

Exempting URLs for flow-based web filtering (252010)

You can once again exempt URLs for flow-based web filtering.

Filter overrides in Application Sensors (246546)

In the Application Sensor page, a new section named **Filter Overrides** has been introduced. From this section, clicking **Add Filter/Edit Filter** will launch a dialog to pick/edit the advanced filter and save it back to the list.

New keyword byte_extract for custom IPS and Application Control signatures (179116)

The new `byte_extract` custom IPS signature key has been added that supports snort-like byte extraction actions. It is used for writing rules against length-encoded protocols. The keyword reads some of the bytes from the packet payload and saves it to a variable. You can use the `-quiet` option to suppress the reporting of signatures.

IPS logging changes (254954)

IPS operations severely affected by disk logging are moved out of the quick scanning path, including logging, SNMP trap generation, quarantine, etc.

Scanning processes are dedicated to nothing but scanning, which results in more evenly distributed CPU usage. Slow (IPS) operations are taken care of in a dedicated process, which usually stays idle.

New FortiGuard web filtering category: Dynamic DNS (265680)

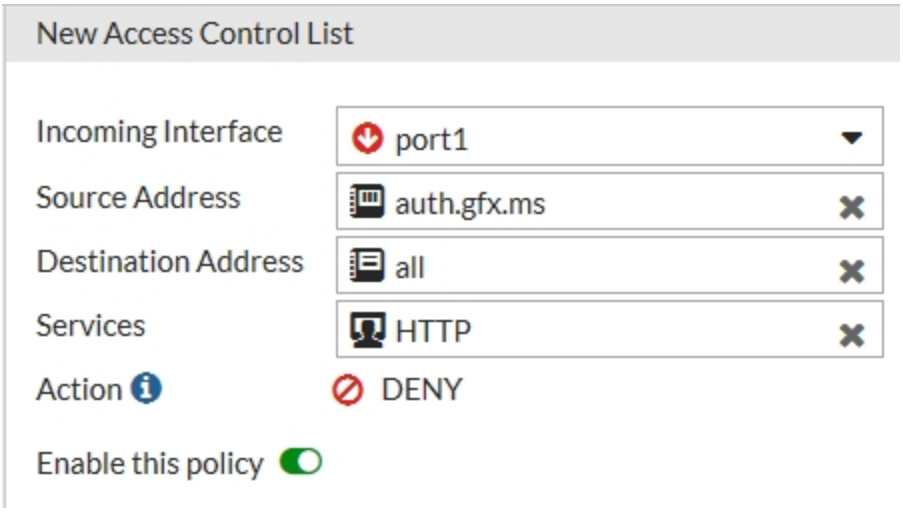
A new FortiGuard web filtering category has been added for **Dynamic DNS** under the **Security Risk** heading, to account for nearly half a million URLs of "Information Technology" rated by BlueCoat as "Dynamic DNS Host".

Syntax

```
config webfilter profile
   edit <profile>
      config ftgd-wf
         config filters
            edit <id>
               set category 88<--- New category, Dynamic DNS; number 88
         end
   end
end
```

Access Control Lists in DoS Policies (293399)

You can go to **Policy & Objects > IPv4 Access Control List** or **Policy & Objects > IPv6 Access Control List** and select an incoming interface and add a list of Firewall source and destination addresses and services and drop traffic that matches.



You can use the following CLI command to add an ACL:

```
config firewall acl
   edit 1
      set interface "port1"
      set srcaddr "google-drive"
      set dstaddr "all"
      set service "ALL"
   next
end
```

Websense web filtering through WISP (287757)

WISP is a Websense protocol that is similar in functionality to ICAP, it allows for URLs to be extracted by a firewall and submitted to Websense systems for rating and approval checking.

This feature provides a solution for customers who have large, existing, deployed implementations of Websense security products to replace their legacy firewalls with a Fortigate family, such that they are not forced to make a change to their web filtering infrastructure at the same time.

In order to use Websense's web filtering service, a WISP server per VDOM needs to be defined and enabled first. A Web filtering profile is then defined that enables WISP, which in turn is applied to a firewall policy.

When WISP is enabled, the FortiGate will maintain a pool of TCP connections to the WISP server. The TCP connections will be used to forward HTTP request information and log information to the WISP server and receive policy decisions.

Syntax

```
config web-proxy wisp
   set status enable
   set server-ip 72.214.27.138
   set max-connection 128
end

config webfilter profile
   edit "wisp_only"
      set wisp enable
   next
end
```

Other new Security Profiles features:

- CPU allocation & tuning commands now remain after a system reboot (276190)
- The GUI notifies an administrator when the FortiGate is in conserve mode (266937)
- A new custom IPS signature option, "--ip_dscp" has been added to be compatible with engine 1.x. (269063)
- The RTP/RTSP decoder can now detect slave sessions (273910)
- ISNIFF can now dump all HTML files if the dump-all-html CLI command is used (277793)
- Sender and recipient fields have been added to flow-based SMTP spam logs (269063)
- Browser Signature Detection added to Application Control profiles (279934)

Session-aware Load Balancing (SLBC)

GUI support for SSL VPN and WiFi controller in SLBC mode (246481)

SSL VPN and WiFi controller GUI pages now appear on the worker GUI when operating in SLBC mode.

Add an option to force IPsec to use NAT Traversal (275010)

Add a new option for NAT. If NAT is set to forced, then the worker will use a port value of zero when constructing the NAT discovery hash for the peer. This causes the peer to think it is behind a NAT device, and it will use UDP encapsulation for IPsec, even if no NAT is present. This approach maintains interoperability with any IPsec implementation that supports the NAT-T RFC.

SSL VPN

This chapter describes new SSL VPN features added to FortiOS 5.4.

Control the cipher suites that can be used by an SSL VPN (304741)

Administrators can now ban the use of specific cipher suites in the CLI for SSL VPN, so PCI-DSS (Payment Card Industry Data Security Standard) certification can be met.

CLI syntax

```
config vpn ssl settings
   set banned-cipher [RSA | DH | DHE | ECDH | ECDHE | DSS | ECDSA | AES | AESGCM |
       CAMELLIA | 3DES | SHA1 | SHA256 | SHA384]
```

SSL VPN monitor enhancements (258700)

SSL VPN monitor GUI page is updated, with additional usability improvements.

Change to SSL VPN authentication (306982)

SSL VPN authentication has been refined to fix an issue regarding authentication policies being ignored.

Local and remote users with multiple groups and policies will authenticate with the first matched policy (user in policy has higher priority), and traffic will go through all matched policies.

Significant SSL VPN web portal improvements (287328, 292726, 299319)

Significant updates and improvements have been made to the SSL VPN web portal in preparation for future browser updates, and in order to support all browsers:

- SSL VPN web portal redesigned.
- SSL VPN tunnel mode widget no longer works in the web portal. The tunnel mode widget used a deprecated NPAPI plugin mechanism to send the tunnel client to the browser for local system execution—this is a popular exploitation vector. FortiClient is now required for tunnel mode SSL VPN.
- SSL VPN Web mode RDP Native java applet removed.
- Removed unnecessary options from RDP bookmark and changed to HTML5 RDP.
- Cache cleaning function has been removed.
- If updating to 5.4.1, see above (258700).

Implement post-authentication CSRF protection in SSL VPN web mode (287180)

This attribute can enable/disable verification of a referrer in the HTTP request header in order to prevent a Cross-Site Request Forgery attack.

Syntax:

```
config vpn ssl settings
   set check-referer [enable|disable]
end
```

Group-based SSL VPN bookmarks (292125)

This CLI-only feature allows administrators to add bookmarks for groups of users. SSL VPN will only output the matched group-name entry to the client.

Syntax:

```
config vpn ssl web portal
   edit "portal-name"
      set user-group-bookmark enable*/disable
   next
end
config vpn ssl web user-group-bookmark
   edit "group-name"
      config bookmark
         edit "bookmark1"
         ....
         next
      end
   next
end
```

DTLS support (227138)

The Datagram Transport Layer Security (DTLS) protocol is supported for SSL VPN connections. DTLS support can be enabled in the CLI as described below.

Syntax

```
config vpn ssl settings
   set dtls-tunnel [enable | disable] (default: enabled)
end
```

Added options to allow firewall addresses to be used in routing table for SSL VPN (265430)

If destination **Named Address** is set in **Network > Static Routes** and **Address Range** is set to **Automatically assign addresses** in **VPN > SSL-VPN Settings**, SSL VPN should refresh the routing table automatically.

HTTP to HTTPS redirect support (278728)

The admin HTTP port can now be redirected to the admin HTTPS port. This is enabled in **VPN > SSL-VPN Settings** using the option **Redirect port 80 to this login port**.

There are two likely scenarios for this:

- SSL VPN is not in use, in which case the admin GUI runs on port 443 or 10443, and port 80 is redirected.
- SSL VPN runs on port 443, in which case port 80 is redirected to 443 and the admin port runs on 10443.

If the administrator chooses to run SSL VPN on port 80, the redirect option is invalid.

This can also be configured in the CLI as described below.

Syntax:

```
config vpn ssl settings
   set https-redirect [enable | disable] (default: disabled)
end
```

Removed guest group and SSO group (303041)

Guest group and SSO group have been removed from `config user group` and `config vpn ssl web user-group-bookmark`.

CLI changes (299319)

Removed the following obsolete/unnecessary portal options from the CLI:

```
config vpn ssl web portal
   edit <name>
      set auto-prompt-mobile-user-download   REMOVED
      set display-forticlient-download   REMOVED
      set display-history-limit   REMOVED
      set page-layout   REMOVED
      set cache-cleaner   REMOVED
   end
```

Removed the following unnecessary RDP bookmark options from the CLI in preparation for HTML5 RDP:

```
config vpn ssl web <user-bookmark|user-group-bookmark>
   edit <group/user name>
      config bookmarks
         edit <bookmark>
            set full-screen-mode   REMOVED
            set screen-height   REMOVED
            set screen-width   REMOVED
            set keyboard-layout   REMOVED
         end
      end
```

System

This chapter describes new system administration features added to FortiOS 5.4.

Incorrect access group for backup and restore config (389328)

FortiOS no longer allows lower level administrator profiles to backup and restore the FortiOS configuration (because this would allow them to acquire hashes for administrator passwords, including super-admin).

Enhancements to IPS Signatures page (285543)

The IPS signatures list page now shows which IPS package is currently deployed. Users can also change their IPS package by linking directly to the FortiGate's **System > FortiGuard** page from the IPS Signatures list page.

Combine multiple commands into a CLI alias (308921)

Multiple commands can be supported under a single command alias defined in the CLI by users.

Configure alias command

```
config system alias
   edit "alias-name" -- Alias command name
      set command "get system status" -- Command list to execute
   next
end
```

Basic config examples (simple command substitution)

```
config sys alias
   edit 1
      set alias "sh ver"
      set cmd "get system status"
   next
   edit 2
      set alias "sh ip route"
      set cmd "get router info routing-table all"
   next
   edit 3
      set alias "sh bgp sum"
      set cmd "get router info bgp summary"
   next
   edit 11
      set alias "debug1"
      set cmd "diag debug enable;diag debug flow show console enable"
   next
   edit 12
      set alias "debug2"
      set cmd "diag debug flow filter saddr"
      set noenter enable
   next
   edit 13
      set alias "debug3"
      set cmd "diag debug flow trace start"
```

```
      set noenter enable
   next
   edit 14
      set "alias debugstop"
      set "cmd diag debug flow trace stop"
   next
end
```

Advanced config examples (parameter substitution)

```
config sys alias
   edit 4
      set alias "sniff (\d+\.\d+\.\d+\.\d+)"
      set cmd "diag sniffer packet any 'host $1' 4"
   next
   edit 5
      set alias "sniff6 (\d+\.\d+\.\d+\.\d+)"
      set cmd "diag sniffer packet any 'host $1' 6"
   next
   edit 6
      set alias "sniff (\S+) (.*)"
      set cmd "diag sniffer packet $1 '$2' 4"
   next
   edit 7
      set alias "trace (\d+\.\d+\.\d+\.\d+) (\d+)"
      set cmd "diag debug enable;diag debug flow show console enable;diag debug flow
          filter saddr $1;diag debug flow trace start $2"
   next
end
```

The `noenter` setting specifies whether the alias substitution should contain a new line or not.

These examples are placed in numerical order.

.

New SNMP trap for bypass events (307329)

When bypass mode is enabled or disabled on FortiGate units that are equipped with bypass interfaces and support AMC modules, a new SNMP trap is generated and logs bypass events.

Maintainer password recovery enhancements (356944)

For information about recovering a lost password and enhancements to the process, see: Resetting a lost Admin password on the Fortinet Cookbook site.

SSH support updated to 7.1p1 (290889)

The OpenSSH daemon has been upgraded from version 3.7.1p2 to version 7.1p1 to support new security algorithms.

The central management FortiGuard server list can include FQDNs (354449)

This new feature implements support of FQDN, to make it an option for central-management server-list. This feature can be set through the GUI and the CLI.

GUI Changes

On **System > FortiGuard > Override FortiGuard Servers > Create New / Edit**, a new option, **FQDN** is added for **Address Type**.

CLI Changes

```
config server-list
   edit 1
      set server-type {update|rating}
      set addr-type {ipv4|ipv6|fqdn} <== added fqdn
      set server-address ipv4
      set server-address6 ipv6
      set fqdn FQDN <== added
   end
```

Features removed from the FortiGate 80C (356154)

Features have been changed on the FortiGate / FortiWifi 80C so as to increase available memory and decrease the image size on flash.

Changes made include:

- removal of web application firewall (WAF)
- removal of WAN optimization
- removal of network vulnerability scan (netscan)
- compression of the Intrusion Prevention System and AntiVirus library files and storing them in a gzip file
- compression of certain WiFi data files
- addition of virtual switch function for 80c (applicable to 5.4 only)

New role property on interfaces (294385)

Interfaces now have a property called 'role' which affects visibility and suggests different default options depending on it's value.

- WAN - this interface is used to connect to the internet.
- LAN - this interface is used to connect to local network of endpoints.
- DMZ - this interface is used to connect to servers.
- Undefined - This interface has a custom role which isn't one of the above.

Interface roles affect visibility of properties and features (295736)

Depending on an interfaces role, some properties may set to a default value and the visibility of others may be set to show or hide in the GUI.

Toggle automatic authorization of extension devices (294966)

When an interface is configured to be dedicated to an extension device, a new option appears to auto-authorize extension devices.

Support for new modem added (293598)

Support for the Linktop LW273 modem has been added.

IPS packet capture files can be backed up (276489)

Use the command `execute backup disk ipsarchives` and the option of `tftp`, `ftp`, or `usb`.

Change between NAT and Transparent modes removed from the GUI (278289)

The feature in the GUI initiating the change between NAT and Transparent modes has been removed. It can still be done, but only through the CLI. The configuration setting that is used is:

```
config system settings
   set opmode [nat | transparent]
   end
```

Switch mode changes (286447)

Hub mode is no longer available. The old switch mode, usually called 'LAN' will no longer be available. The interface mode is still available and on all models, and instead of the old switch mode, most of the lower end units will come configured, by default, with a hardware switch called 'LAN', which has the function of the old switch mode but is more flexible. Most models with 40 ports or more will come by default in vlan switch mode.

New start attribute as been added to scheduled scripts (285206)

The start attribute has the options manual and auto. Manual means a schedule script needs to be manually started after a reboot. Auto automatically restarts the script after a reboot.

Use the following command to set a script to automatically run after the FortiGate starts up:

```
config system auto-script
   edit <script-name>
      set start auto
   end
```

Toggle displaying the hostname on the GUI login page (272572)

Use the following command:

```
config sys settings
   set gui-display-hostname {disable | enable}
end
```

PPTP and L2TP address pool ranges expanded (275709)

PPTP and L2TP address pool ranges are allowed to use a subnet mask of up to 255.255.0.0 (B-class), increasing the maximum range size from 254 to 65,534

Pop up notification of impending timeout of Administrator GUI sessions (266413)

A convenience feature to let administrators know that their session is about to expire. This is especially convenient for units that have a timeout setting of just a few minutes.

SNMP can generate traps based on detecting a device's online/offline status (273107)

This setting is related to the device detection feature. It allows SNMP traps to detect when a new device comes online. Within SNMP configurations there is a configurable timeout setting that periodically checks for the device. When a check determines that the device is present a trap is sent.

In the GUI, when configuring an SNMP object, one of the settings is a checkbox, under **SNMP Events** for **Device detected**.

To configure the SNMP object in the CLI use the following syntax:

```
config system snmp community
   edit <community ID number>
      set name <string>
      set events device-new
      end
```

In order to configure the idle timeout for the device, use the following syntax in the CLI:

```
config system global
   set device-idel-timeout <integer of time in seconds>
   end
```

The time value for the field can be set from 30 to 31536000.

SNMP improvements for dynamic routing (168927)

SNMP improvements for dynamic routing include support for RFC 4750 OSPF Version 2 Management Information Base and RFC 5643 Management Information Base for OSPFv3. These changes add the capability of logging dynamic routing activity. Examples include sending OSPF routing events or changes to a syslog server or FortiAnalyzer or changes in neighborhood status.

Network Mobility Extensions for Mobile IPv4 (NEMO)

This is an implementation of RFC 5177 that includes the following CLI command.

```
config system mobile-tunnel
   set status enable/disable //Enable/disable this mobile tunnel.
   set roaming-interface port1 //Roaming interface name.
   set home-agent xxx.xxx.xxx.xxx //IP address of the NEMO HA.
   set home-address xxx.xxx.xxx.xxx // Home IP address.
   set n-mhae-spi 256 //NEMO authentication spi.
   set n-mhae-key-type ascii/base64 //NEMO authentication key type.
   set n-mhae-key vWZZxx //NEMO authentication key.
   set hash-algorithm hmac-md5 //Hash Algorithm.
   set tunnel-mode gre //NEMO tunnnel mode.
   set renew-interval 60 //Time before lifetime expiraton to send NMMO HA re-registration.
   set lifetime 180 //NEMO HA registration request lifetime.
   set reg-interval 5 //NEMO HA registration interval.
   set reg-retry 3 //NEMO HA registration maximal retries.
end
```

Restoring configuration file without rebooting the FortiGate (237786)

A setting has been added in the CLI that when set to enable, will allow the FortiGate to start using the newly uploaded configuration file without going through a full reboot process.

The syntax for the setting is:

```
config system global
   set reboot-upon-config-restore {enable | disable}
end
```

Auto repeat of CLI commands(160023 259531)

Occasionally there is a need to repeatedly run a diagnose command over a long period of time (like checking CPU or memory usage, or checking proxy health), Previously, this could only be done with external console connections. Now this can be done in a script using the `interval` and `repeat` commands.

Scripts can be uploaded as a file from the CLI or GUI. To upload scripts from the GUI go to **System > Advanced > Configuration Scripts** and upload and run the script.

To configure the schedule and scripts, use the following syntax:

```
config system auto-script
   edit <ScriptName>
      set interval
      set repeat
      set script
   end
end
```

`interval` the interval time in seconds between instances of the script running.

`repeat` the number of times to repeat the running of the script. The value 0 is used to set an infinite number of repetitions.

`start` select `manual` to start the script manually or `auto` to start the script automatically

`script` the contents of the script.

This feature may not be available on all models as a hard drive is necessary to make use of it.

Proxy-arp function extension (250651)

A new attribute `end-ip` is added to proxy-arp. If `end-ip` is not set, then the ip has the same meaning as before. If `end-ip` is set, then the ip becomes the start-ip, and the `end-ip` should be larger than ip and the ip range should less than 256.

```
config system proxy-arp
   edit 1
      set interface internal
      set ip xxx.xxx.xxx.xxx
      set end-ip xxx.xxx.xxx.xxx
   next
end
```

Changes to the FortiGuard Distribution Network GUI page (219862)

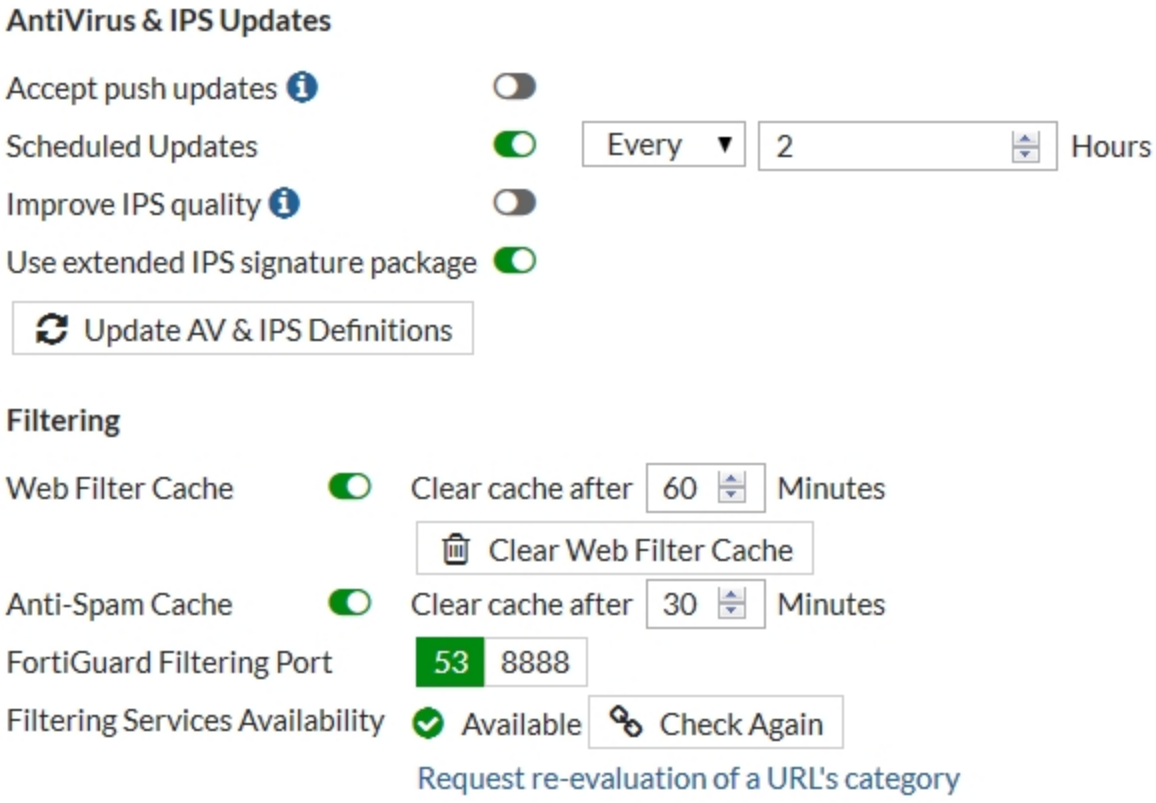
The **System > FortiGuard** page has been updated to include new FortiGuard features including Mobile Malware Definitions, Botnet Definitions and so on. From this page you can also upload packages, and view the list of Botnet Definitions.

FortiGuard Distribution Network

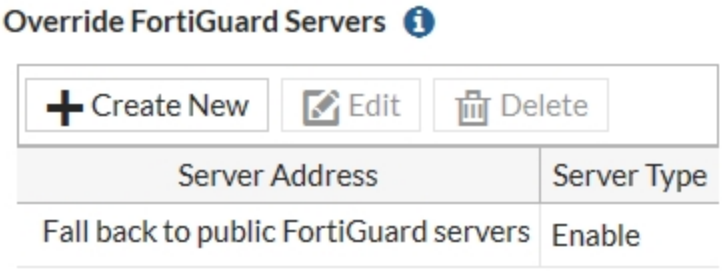
License Information

Contract	Status	
FortiCare Support	Registered (kleroux@fortinet.com)	Launch Portal
Hardware Version	8 x 5 support (Expires on 2016-09-29)	
Comprehensive Support	24 x 7 support (Expires on 2016-09-29)	
Firmware	8 x 5 support (Expires on 2016-09-29)	
Enhanced Support	24 x 7 support (Expires on 2016-09-29)	
IPS & Application Control	Licensed (Expires on 2016-09-29)	Upload Package
IPS Definitions	Version 6.00755	
IPS Engine	Version 3.00156	
AntiVirus	Licensed (Expires on 2016-09-29)	Upload Package
AV Definitions	Version 31.00354	
AV Engine	Version 5.00227	
Mobile Malware Definitions	Version 0.00000	
Botnet Definitions	Version 2.00684	View List
SSL-VPN Package	Unreachable	Upload Package
Web Filtering	Licensed (Expires on 2016-09-29)	
Anti-Spam Filtering	Licensed (Expires on 2016-09-29)	

From this page you can also access new functionality for AntiVirus and IPS updates and Web Filtering and Spam filtering.



You can also use this page to override FortiGuard servers.



Changes to firmware upgrade GUI page (248866)

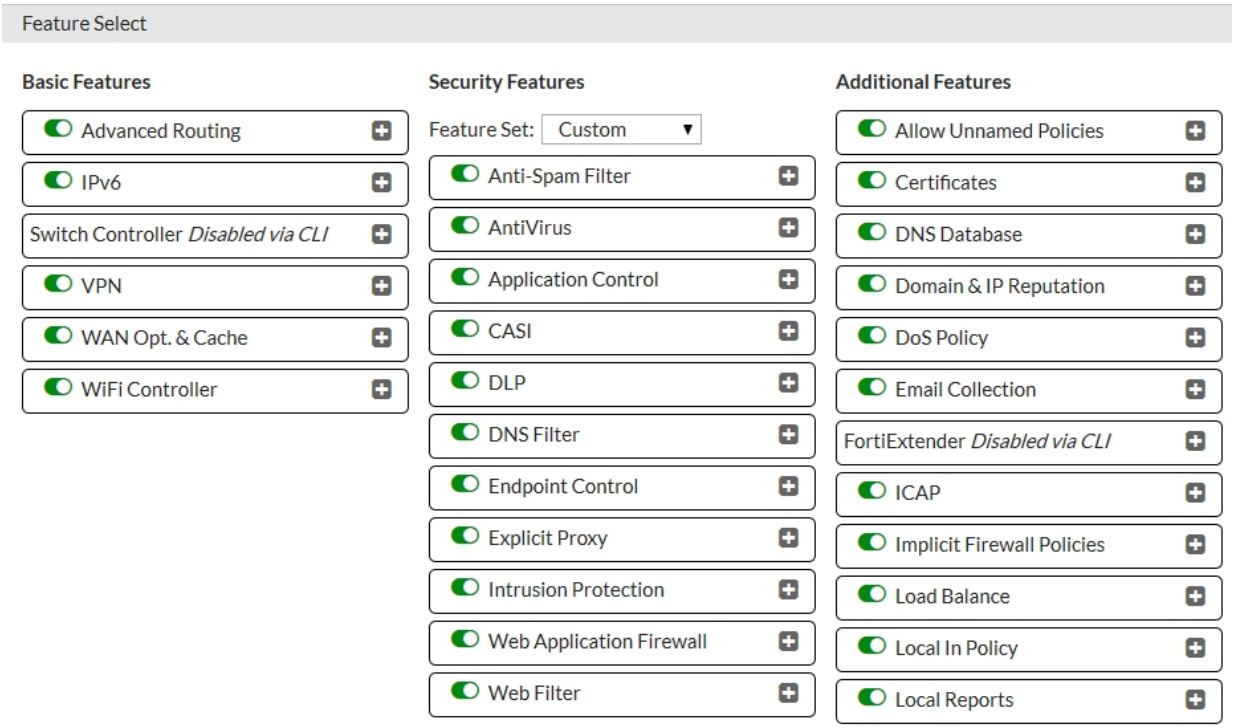
The following changes have been made to the GUI as it relates to the firmware upgrade process:

- The interface now provides an upgrade recommendations that is based on FortiGuard's list of supported upgrade paths
- Allows user to easily select and upgrade to one of the recommended versions
- There is a graphic representation of the progress of downloading the image and the upgrade process.

GUI features can now be enabled and disabled per VDOM (263708 273799)

When VDOMs are enabled, most of the items in the Features section of the menu are moved to a similar menu section within the VDOM menu and are now customizable on a per VDOM basis. Some items such as IPv6 and Certificates are still configured on a global basis.

From the GUI, you can enable or disable GUI features from **System > Feature Select**.

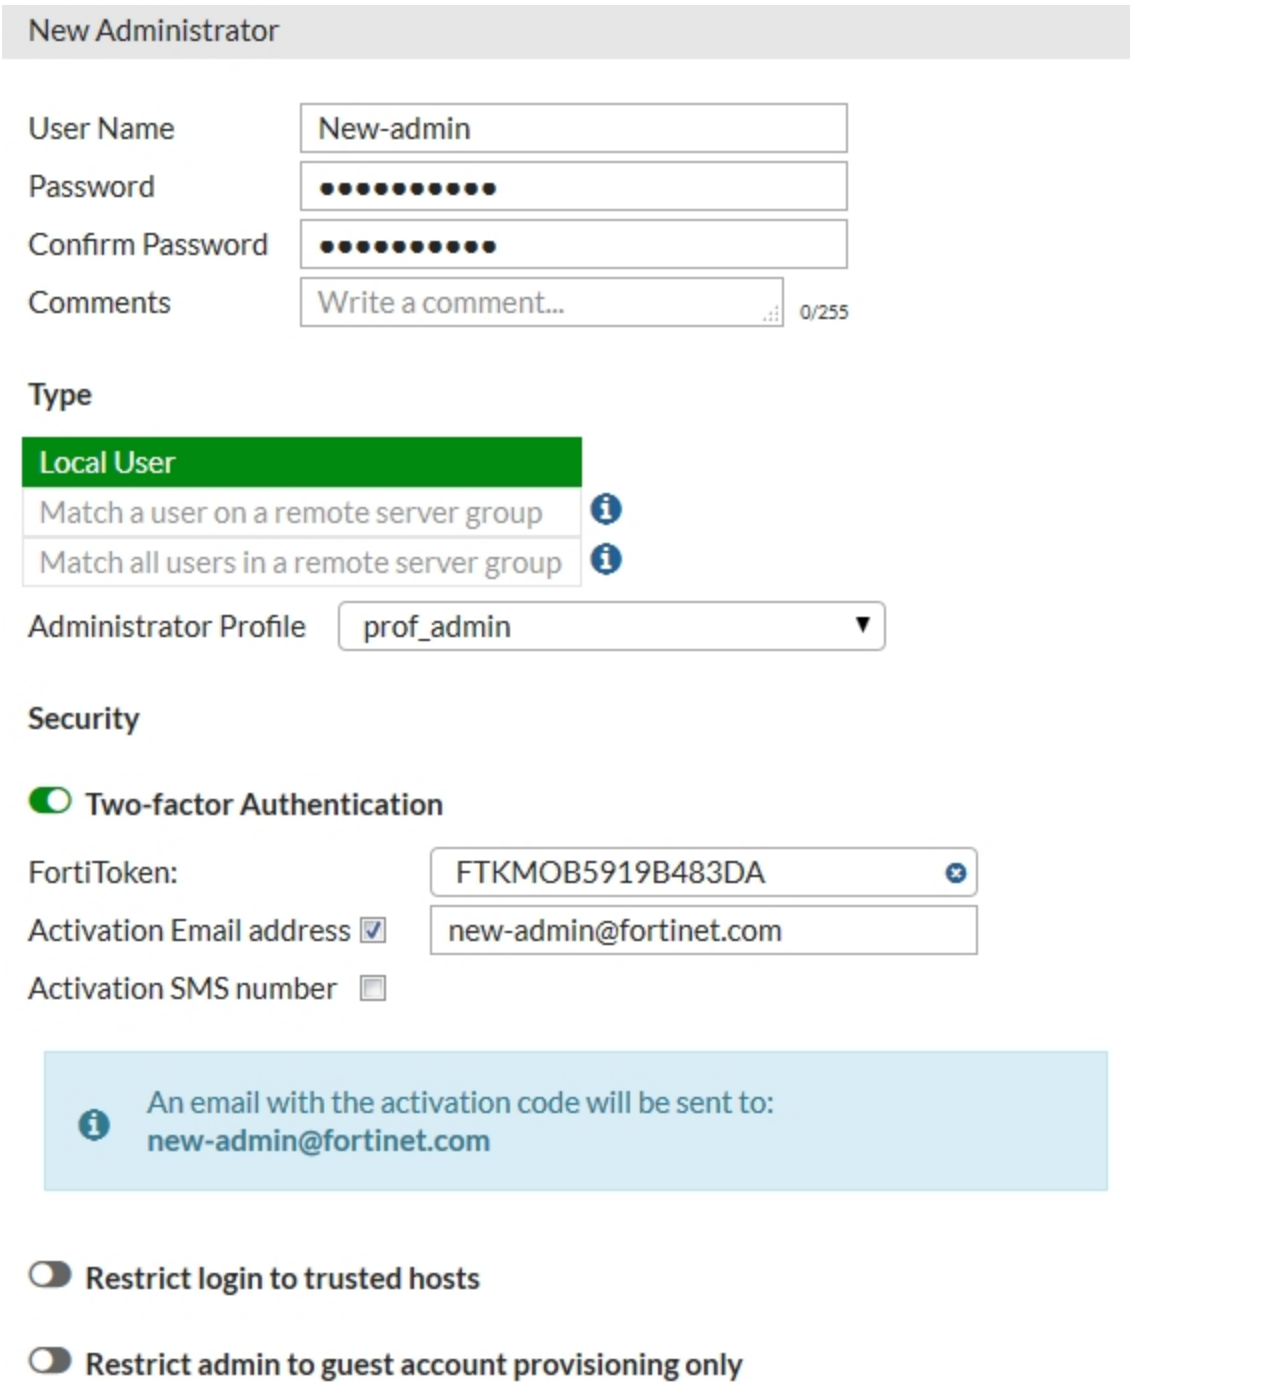


From the CLI, GUI items that are enabled or disabled per-VDOM are configured from the `config system settings` command. GUI items that are enabled globally are enabled or disabled from the `config system global` command.

Turning these features on or off does not enable or disable the feature but determines whether or not that option is displayed on the GUI.

Improvements to system admin GUI pages (205280)

Several items relating to system administration, and the configuration of the system administrator accounts and profiles in particular, have been updated so that the layout is clearer and more efficient. One of the things improve is that it is now easier to set up two factor authentication.



The TFTP session helper supports (263127)

The TFTP session helper supports TFTP for NAT66 and NAT46.

Support for IPv6 addressing when configuring central management (297144)

Previously, the configuration of an IP address for a server for ratings and updates, such as a FortiManager, could only use IPv4 addresses. Now, as shown below IPv6 addressing can be used as well.

```
config system central-management
   set type fortimanager
   set fmg "2000:172:16:200::207"
   set vdom "vdom1"
      config server-list
         edit 1
         set server-type rating update
         set addr-type ipv6
         set server-address6 2000:172:16:200::207
         next
      end
   end
```

New execute traceroute command options (272169)

Different query options can be configured for the `execute traceroute` command. These settings can also be saved using the `execute traceroute-options` command as follows:

```
execute traceroute-options device [Auto | <interface name>]
execute traceroute-options queries <integer>
execute traceroute-options source [Auto | <source interface IP address>]
```

The `queries` setting is to determine the number of queries per hop. Use execute traceroute-options to view the traceroute settings:

```
execute traceroute-options view-settings
Traceroute Options:
       Number of probes per hop: 3
       Source Address: auto
       Device: auto
```

Administrator password updates (292858)

To set a minimum level of security for the administrative accounts, minimum levels of complexity can be set on guest admin accounts.

```
config system password-policy-guest-admin
   set status [enable | disable]
   set min-lower-case-letter <integer>
   set min-upper-case-letter <integer>
   set min-non-alphanumeric <integer>
   set min-number <integer>
   end
```

If the required level of complexity is not met, an error message will appear explaining that the password must conform to the system password policy.

Certificate validation added to FortiGate email server configuration (299506)

When configuring the email server on a FortiGate to send out alert emails that use SMTPS, the FortiGate can validate the email chain, thus reducing the possibility of compromise.

In the CLI the configuration of the email is set up with the following syntax:

```
config system email-server
   set type custom
   set reply-to <email address>
   set server <SMTP server IP address or hostname>
   set port <integer for SMTP server port>
```

```
set source-ip <SMTP server source address - IPv4 format>
set source-ip6 <SMTP server source address - IPv6 format>
set authenticate [enable| disable]
set validate-server [enable| disable]
security Connection security.
set security [none | starttls |smtps|
end
```

The `set validate-server` option is the new setting that enables the verification.

Changes to backing up and restoring configuration files (298176)

When you insert a USB drive into a FortiGate USB port options to save the configuration to USB and restore configuration from a USB appear on the configureation save and restore pages.

You can also use the command `execute backup usb` command to backup the configuration to the USB drive.

VDOMs

This chapter describes new VDOM features added to FortiOS 5.4.

Cooperative Security Fabric (CSF) firewalls do not support multiple VDOMs (365260)

This problem should be fixed in a future release.

VDOM name search added to GUI navigation (305221)

When selecting a VDOM you can search by name instead of manually searching through the entire list.

Stackable VDOM licenses (269153)

VDOM licenses are now stackable, allowing you to buy additional licenses and stack them on top existing licenses to increase the number of VDOMs you can have.

Support execution of global CLI commands from within VDOMs (262848)

A new CLI command, `sudo`, allows the running of global commands from within the vdom context of the CLI.This means that the user no longer has to:

1. exit from the VDOM
2. enter global
3. run the command
4. return to the previous VDOM

The syntax for the command is:

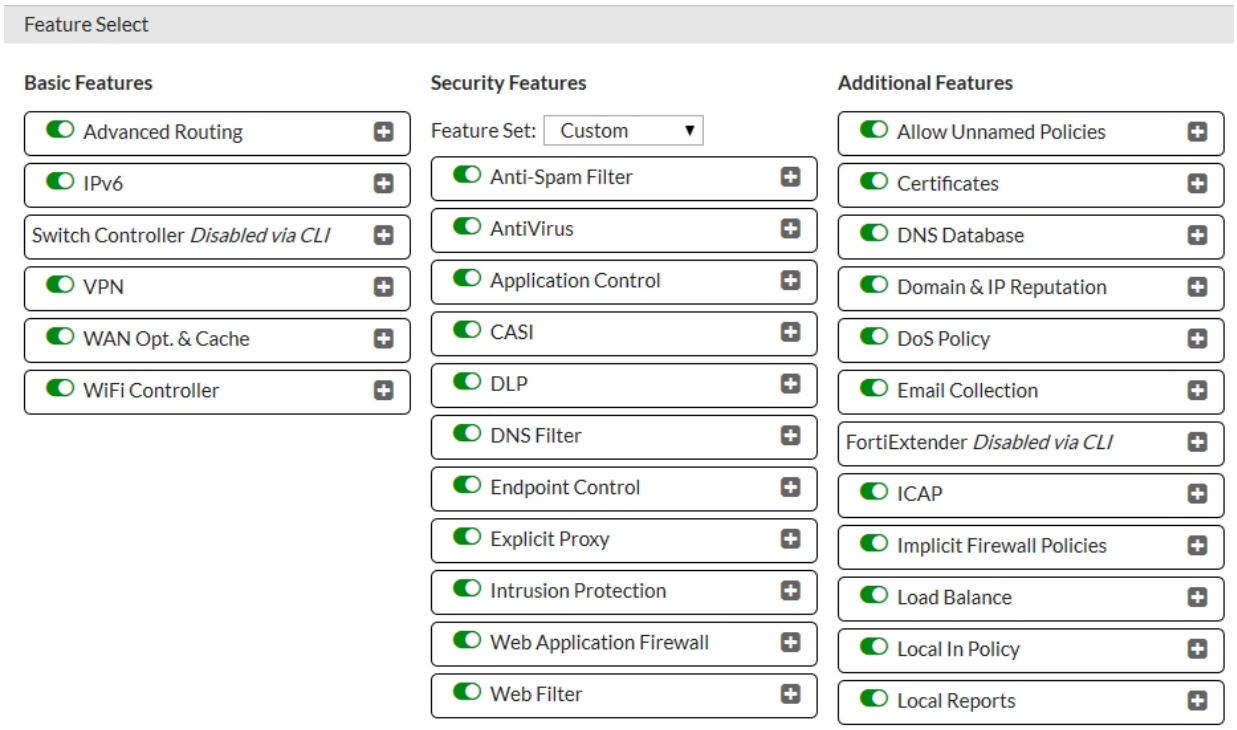
```
sudo {global | vdom-name} {diagnose | execute | show | get}
```

These commands will only work if the user already has permissions to run the command. Unlike the sudo command in some other operating systems like Linux, this command does not allow the user to run programs with the privileges of another user.

GUI features can now be enabled and disabled per VDOM (263708 273799 266028)

When VDOMs are enabled, most of the items in the Features section of the menu are moved to a similar menu section within the VDOM menu and are now customizable on a per VDOM basis. Some items such as IPv6 and Certificates are still configured on a global basis.

From the GUI, you can enable or disable GUI features from **System > Feature Select**.



From the CLI, GUI items that are enabled or disabled per-VDOM are configured from the `config system settings` command. GUI items that are enabled globally are enabled or disabled from the `config system global` command.

Turning these features on or off does not enable or disable the feature but determines whether or not that option is displayed on the GUI.

WAN Optimization

Toggle Disk Usage for logging or wan-opt (290892)

Both logging and WAN Optimization use hard disk space to save data. For FortiOS 5.4 you cannot use the same hard disk for WAN Optimization and logging.

- If the FortiGate has one hard disk, then it can be used for either disk logging or WAN optimization, but not both. By default, the hard disk is used for disk logging.
- If the FortiGate has two hard disks, then one disk is always used for disk logging and the other disk is always used for WAN optimization.

WAN Optimization is **not** supported while the FortiGate is in **Flow-based** inspection.

On the FortiGate, go to **System > Advanced > Disk Settings** to switch between **Local Log** and **WAN Optimization**.

You can also change disk usage from the CLI using the following command:

```
configure system global
   set disk-usage {log | wanopt}
end
```

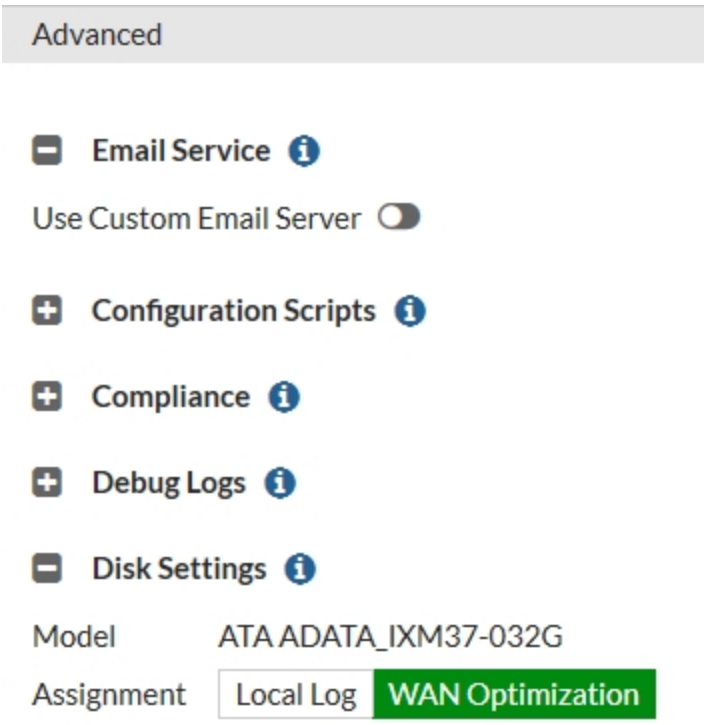
The Toggle Disk Usage feature is supported on all new "E" Series models, while support for "D" Series models may vary.

Please refer to the Feature Platform Matrix for more information.

Changing the disk setting formats the disk, erases current data stored on the disk and disables either disk logging or WAN Optimization.

You can configure WAN Optimization from the CLI or the GUI. To configure WAN Optimization from the GUI you must go to **System > Feature Select** and turn on WAN Optimization.

Remote logging (including logging to FortiAnalyzer and remote Syslog servers) is not affected by using the single local hard disk for WAN Optimization.



Enabling WAN Optimization affects more than just disk logging

In addition to affecting WAN Optimization, the following table shows other features affected by the FortiGate disk configuration.

Features affected by Disk Usage as per the number of internal hard disks on the FortiGate

Feature	Logging Only (1 hard disk)	WAN Opt. Only (1 hard disk)	Logging & WAN Opt. (2 hard disks)
Logging	Supported	Not supported	Supported
Report/Historical FortiView	Supported	Not supported	Supported
Firewall Packet Capture (Policy Capture and Interface Capture)	Supported	Not supported	Supported
AV Quarantine	Supported	Not supported	Supported
IPS Packet Capture	Supported.	Not supported	Supported
DLP Archive	Supported	Not supported	Supported

Feature	Logging Only (1 hard disk)	WAN Opt. Only (1 hard disk)	Logging & WAN Opt. (2 hard disks)
Sandbox DB & Results	FortiSandbox database and results are also stored on disk, but will not be affected by this feature.		

MAPI AV scanning is supported over WAN Optimization (267975)

AV works on MAPI when WAN Optimization is used.

WiFi

This chapter describes new WiFi features added to FortiOS 5.4.

Conflicting local-standalone and local-bridging VAP CLI resolved (256450)

- Disabling local-bridging now forcefully disables local-standalone. Also, disabling either local-bridging or local-standalone now forcefully disables intra-vap-privacy.
- Enabling intra-vap-privacy now forcefully disables local-standalone.
- Local-bridging will be forcefully enabled when local-standalone is also enabled.

Support fast-roaming for mesh backhaul link (274007 293321)

Added basic functionality required to make a leaf FortiAP able to roam fast enough from one root FortiAP to another when signal conditions change. The feature allows administrator to tune the fast roaming for most mobility scenarios. The leaf FAP is used as a wireless bridge passing traffic from the Ethernet port to the wireless mesh link.

- Includes background scan while the leaf AP is connected to the root AP (Mesh uplink established)
- Leaf AP will schedule a background scan using local interfaces (wbh0/1)
- Scan parameters are configured in the AP
- Every 10 minutes, WTP daemon reviews list of available root AP. If a better root AP is found, WTP daemon triggers a mesh roaming.

For full leaf AP scan mesh CLI variables, see Mesh variables on page 1499.

Captive portal authentication to support roaming (284202 306681)

Client devices will maintain captive portal authentication as they roam across different APs. By maintaining a consistent authentication, a client can ensure uninterrupted access to latency sensitive applications such as VoIP.

Cloud will push a random per-APNetwork encrypt key to AP. The encrypt key is 32 bytes length, and will be used in captive portal fast roaming. All APs of an APNetwork will use one same encrypt key. This encrypt key is randomly generated, and will be updated daily.

Link aggregation supports CAPWAP to improve WiFi performance (305156)

Link aggregation is used to combine multiple network connections in parallel in order to increase throughput beyond what a single connection could sustain.

- FortiAP 320B and 320C models are supported.
- FortiAP 112B and 112D models **cannot** support link aggregation.
- NPI FAP-S3xxCR and "wave2" FAP/FAP-S models will have link aggregation feature via synchronization with regular FortiAP trunk build.

Link aggregation can be set in the FortiAP's C LI. See FortiAP CLI for more information.

Blocking management access via non-management interface (307813)

Previously, FortiAP accepted Telnet and HTTP connection to any virtual interfaces that have an IP address. For security reasons, Telnet and HTTP access are now limited to br0 or br.vlan for AP_MGMT_VLAN_ID.

Support HTTPS and SSH administrative access for FortiAPs (355122)

FortiAP now supports HTTPS and SSH administrative access, as well as HTTP and Telnet.

CLI additions have been made under wtp-profile and wtp.

Syntax

```
config wireless-controller wtp-profile
   edit {profile}
      set allowaccess [telnet | http | https | ssh]
   end

config wireless-controller wtp
   edit 1
      set override-allowaccess [enable | disable]
      set allowaccess [telnet | http | https | ssh]
   end
```

Support to Disable PowerSave Feature (355273)

Added `transmit-optimize` under `wireless-controller wtp-profile` > `radio` to manually configure transmit optimization.

Syntax

```
config wireless-controller wtp-profile
   edit {profile}
      config {radio}
         set transmit-optimize [disable | power-save | aggr-limit | retry-limit | send-
             bar]
```

- **disable:** Disable transmit optimization.
- **power-save:** Mark a client as power save mode if excessive transmit retries happen.
- **aggr-limit:** Set aggregation limit to a lower value when data rate is low.
- **retry-limit:** Set software retry limit to a lower value when data rate is low.
- **send-bar:** Do not send BAR frame too often.

ARP not resolved for IPADs (364516)

Added the `arp-proxy` option under `config wireless-controller vap` > `set broadcast-suppression` to configure VAP to reply ARP requests for wireless clients as a proxy.

Option to block intra-SSID traffic in Bridge mode for client connected to same FortiAP (365128)

A FortiAP in Bridge mode can now block traffic to clients associated with same FortiAP. This is useful in hotspot deployments managed by a central FortiGate, but would also be useful in cloud deployments. Until now,this was

only supported in Tunnel mode.

Run FortiAP shell command through CAPWAP control tunnel (365609)

Very often, the FortiAP in the field is behind a NAT device, and access to the FortiAP through Telnet or SSH is not available. As a troubleshooting enhancement, this feature allows an AP shell command up to 127-bytes sent to the FAP, and FAP will run this command, and return the results to the controller using the CAPWAP tunnel.

Maximal output from a command is limited to 4M, and the default output size is set to 32K.

The FortiAP will only report running results to the controller after the command is finished. If a new command is sent to the AP before the previous command is finished, the previous command will be canceled.

Syntax

```
diag w-c wlac wtpcmd wtp_ip wtp_port cmd [cmd-to-ap]
cmd: run,show,showhex,clr,r&h,r&sh
```

- **cmd-to-ap:** any shell commands, but AP will not report results until the command is finished on the AP
- **run:** controller sends the ap-cmd to the FAP to run
- **show:** show current results reported by the AP in text
- **showhex:** show current results reported by the AP in hex
- **clr:** clear reported results
- **r&s:** run/show
- **r&sh:** run/showhex

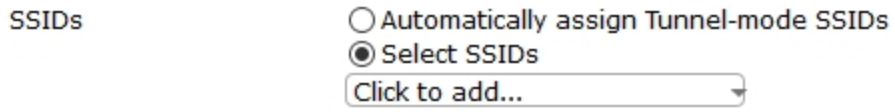
New Certificate Bundle 20160525 is available (373743)

A new WiFi certificate bundle is available, issued by Entrust. The chain is: wifi_cert > Entrust_L1K > Entrust_G2 > Entrust_Root.

Per Entrust's request, unpopular G2 root is removed from CA bundle.

Automatic all-SSID selection in FortiAP Profile (219347)

The SSID field in FortiAP Profiles now includes the option **Automatically assign Tunnel-mode SSIDs**. This eliminates the need to re-edit the profile when new SSIDs are created. You can still select SSIDs individually using the **Select SSIDs** option.



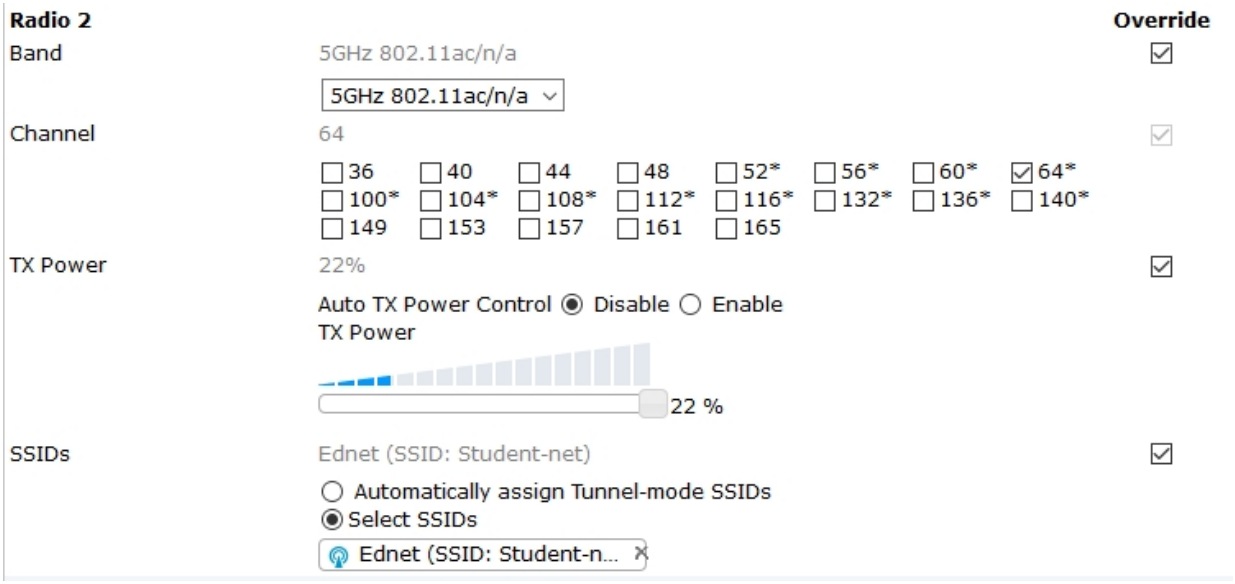
Automatic assignment of SSIDs is not available for FortiAPs in Local Bridge mode. The option is hidden on both the Managed FortiAP settings and the FortiAP Profile assigned to that AP.

Improved override of FortiAP settings (219347 264010 264897)

The configuration settings of a FortiAP in **WiFi Controller > Managed FortiAPs** can override selected settings in the FortiAP Profile:

- Band and/or Channel
- Transmitter Power
- SSIDs
- LAN Port mode

Note that a Band override also overrides Channel selections.



In the CLI, you can also override FortiAP LED state, WAN port mode, IP Fragmentation prevention method, spectrum analysis, and split tunneling settings.

Spectrum Analysis removed from FortiAP Profile GUI

Spectrum Analysis is no longer available in FortiAP Profiles in the GUI. It can be enabled in the CLI if needed.

Disable low data rates in 802.11a, g, n ac (297821)

To reduce air-time usage on your WiFi network, you can disable the use of low data rates which cause communications to consume more air time.

The 802.11 a, b, and g protocols are specified by data rate. 802.11a can support 6,9,12, 18, 24, 36, 48, and 54 Mb/s. 802.11b/g can support 1, 2, 5.5, 6, 9,12, 18, 24, 36, 48, 54 Mb/s. Basic rates are specified with the suffix "basic", "12-basic" for example. The capabilities of expected client devices need to be considered when deciding the lowest Basic rate.

The 802.11n and ac protocols are specified by MSC (Modulation and Coding Scheme) Index and the number of spatial streams.

- 802.11n with 1 or 2 spatial streams can support mcs0/1, mcs1/1, mcs2/1, mcs3/1, mcs4/1, mcs5/1, mcs6/1, mcs7/1,mcs8/2,mcs9/2, mcs10/2, mcs11/2, mcs12/2, mcs13/2, mcs14/2, mcs15/2.
- 802.11n with 3 or 4 spatial streams can support mcs16/3, mcs17/3, mcs18/3, mcs19/3, mcs20/3, mcs21/3, mcs22/3, mcs23/3, mcs24/4, mcs25/4, mcs26/4, mcs27/4, mcs28/4, mcs29/4, mcs30/4, mcs31/4.
- 802.11ac with 1 or 2 spatial streams can support mcs0/1, mcs1/1, mcs2/1, mcs3/1, mcs4/1, mcs5/1, mcs6/1, mcs7/1, mcs8/1, mcs9/1, mcs0/2, mcs1/2, mcs2/2, mcs3/2, mcs4/2, mcs5/2, mcs6/2, mcs7/2, mcs8/2, mcs9/2.

- 802.11ac with 3 or 4 spatial streams can support mcs0/3, mcs1/3, mcs2/3, mcs3/3, mcs4/3, mcs5/3, mcs6/3, mcs7/3, mcs8/3, mcs9/3, mcs0/4, mcs1/4, mcs2/4, mcs3/4, mcs4/4, mcs5/4, mcs6/4, mcs7/4, mcs8/4, mcs9/4

Here are some examples of setting basic and supported rates.

```
config wireless-controller vap
   edit <vap_name>
      set rates-11a 12-basic 18 24 36 48 54
      set rates-11bg 12-basic 18 24 36 48 54
      set rates-11n-ss34 mcs16/3 mcs18/3 mcs20/3 mcs21/3 mcs22/3 mcs23/3 mcs24/4 mcs25/4
      set rates-11ac-ss34 mcs0/3 mcs1/3 mcs2/3 mcs9/4 mcs9/3
   end
```

WiFi and Switch controllers are enabled separately (275860)

In the Feature Store (**System > Features**), the WiFi Controller and Switch Controller are now separate. However, the Switch Controller must be enabled in order for the WiFi Controller to be visible.

In the CLI, the settings that enable the WiFi and Switch controllers have been separated:

```
config system global
   set wireless-controller enable
   set switch-controller enable
end
```

The settings that enable the GUI display for those controllers have also been separated:

```
config system settings
   set gui-wireless-controller enable
   set gui-switch-controller enable
end
```

Add Support of LLDP protocol on FortiAP to send switch and port information (283107)

You can enable LLDP protocol in the FortiAP Profile. Each FortiAP using that profile can then send back information about the switch and port that it is connected to. This information is visible in the optional LLDP column of the Managed FortiAP list. To enable LLDP:

```
config wireless-controller wtp-profile
   edit <profile-name>
      set lldp enable
   end
```

WTP groups (278462)

You can define FortiAP Groups. Each group can contain FortiAPs of a single platform (model). These groups can be used in VLAN-pooling to assign APs to particular VLANs. Create a FortiAP Group in the CLI like this:

```
config wireless-controller wtp-group
   edit 1
      set platform-type 320C
      config wtp-list
         edit FP320C3X14010828
         next
         edit FP320C3X14010830
         end
      end
```

The `platform-type` field is optional. If it is left empty, the group can contain FortiAPs of any model.

VLAN-pooling (278462)

In an SSID, you can define a VLAN pool. As clients associate to an AP, they are assigned to a VLAN. A VLAN pool can

- assign a specific VLAN based on the AP's FortiAP Group, usually for network configuration reasons, or
- assign one of several available VLANs for network load balancing purposes (tunnel mode SSIDs only)

Assignment by FortiAP Group

In this example, VLAN 101, 102, or 103 is assigned depending on the AP's FortiAP Group.

```
config wireless-controller vap
   edit wlan
      set vlan-pooling wtp-group
      config vlan-pool
         edit 101
            set wtp-group wtpgrp1
         next
         edit 102
            set wtp-group wtpgrp2
         next
         edit 103
            set wtp-group wtpgrp3
         end
      end
```

Load Balancing

The vlan-pooling type can be either of these:

- **round-robin** - from the VLAN pool, choose the VLAN with the smallest number of clients
- **hash** - choose a VLAN from the VLAN pool based on a hash of the current number of SSID clients and the number of entries in the VLAN pool

If the VLAN pool contains no valid VLAN ID, the SSID's static VLAN ID setting is used.

In this example, VLAN 101, 102, or 103 is assigned using the round-robin method:

```
config wireless-controller vap
   edit wlan
      set vlan-pooling round-robin
      config vlan-pool
         edit 101
         next
         edit 102
         next
         edit 103
      end
   end
```

Option to disable automatic registration of unknown FortiAPs (272368)

By default, FortiGate adds newly discovered FortiAPs to the Managed FortiAPs list, awaiting the administrator's authorization. Optionally, you can disable this automatic registration function. A FortiAP will be registered and listed only if its serial number has already been added manually to the Managed FortiAPs list. AP registration is configured on each interface. Disable automatic registration in the CLI like this:

```
config system interface
   edit port15
      set ap-discover disable
   end
```

Automatic authorization of extension devices

To simplify adding FortiAP or FortiSwitch devices to your network, you can enable automatic authorization of devices as they are connected, instead of authorizing each one individually. This feature is available only on network interfaces designated as Dedicated to Extension Device.

To enable automatic authorization on all dedicated interfaces

```
config system global
   set auto-auth-extension-device enable
end
```

To enable automatic authorization per-interface

```
config system interface
   edit port15
      set auto-auth-extension-device enable
   end
```

In the GUI, the **Automatically authorize devices** option is available when **Addressing Mode** is set to **Dedicated to Extension Device**.

Control WIDS client deauthentication rate for DoS attack (285674 278771)

As part of mitigating a Denial of Service (DoS) attack, the FortiGate sends deauthentication packets to unknown clients. In an aggressive attack, this deauthentication activity can prevent the processing of packets from valid clients. A new WIDS Profile option in the CLI limits the deauthentication rate.

```
config wireless-controller wids-profile
   edit default
      set deauth-unknown-src-thresh 10
   end
```

The range is 1 to 65,535 deathorizations per second. 0 means no limit. The default is 10.

Prevent DHCP starvation (285521)

The SSID broadcast-suppression settings in the CLI now include an option to prevent clients from depleting the DHCP address pool by making multiple requests. Add this option as follows:

```
config wireless-controller vap
   edit "wifi"
      append broadcast-suppression dhcp-starvation
   end
```

Prevent ARP Poisoning (285674)

The SSID broadcast-suppression settings in the CLI now include an option to prevent clients from spoofing ARP messages. Add this option as follows:

```
config wireless-controller vap
   edit "wifi"
      append broadcast-suppression arp-poison
   end
```

Suppress all other multicast/broadcast packets (282404)

The SSID broadcast-suppression field in the CLI contains several options for specific multicast and broadcast packet types. Two new options suppress multicast (mc) and broadcast (bc) packets that are not covered by any of the specific options.

```
config wireless-controller vap
   edit "wifi"
      append broadcast-suppression all-other-mc all-other-bc
   end
```

A new configurable timer flushes the wireless station presence cache (283218)

The FortiGate generates a log entry only the first time that station-locate detects a mobile client. No log is generated for clients that have been detected before. To log repeat client visits, previous station presence data must be deleted (flushed). The sta-locate-timer can flush this data periodically. The default period is 1800 seconds (30 minutes). The timer can be set to any value between 1 and 86400 seconds (24 hours). A setting of 0 disables the flush, meaning a client is logged only on the very first visit.

The timer is one of the wireless controller timers and it can be set in the CLI. For example:

```
config wireless-controller timers
   set sta-locate-timer 1800
end
```

The sta-locate-timer should not be set to less than the sta-capability-timer (default 30 minutes) because that could cause duplicate logs to be generated.

Distributed Automatic Radio Resource Provisioning (DARRP) support (283501)

Through DARRP, each FortiAP unit autonomously and periodically determines the channel that is best suited for wireless communications. The distributed ARRP feature allows FortiAP units to select their channel so that they do not interfere with each other in large-scale deployments where multiple access points have overlapping radio ranges. Furthermore, Fortinet's implementation of DARRP simplifies operations by removing dependency on client software or hardware.

By default, DARRP optimization occurs at a fixed interval of 1800 seconds. Optionally, you can now schedule optimization for a fixed time. This enables you to confine DARRP activity to a low-traffic period. Setting `darrp-optimize` to 0, makes `darrp-day` and `darrp-time` available. For example, here's how to set DARRP optimization for 3:00am every day:

```
config wireless-controller timers
   set darrp-optimize 0
   set darrp-day sunday monday tuesday wednesday thursday friday saturday
   set darrp-time 03:00
```

```
    end
```

Both `darrp-day` and `darrp-time` can accept multiple entries.

The FAP-320C, 320B and 112B second WAN port can be configured as a LAN bridge (261415)

This change makes FortiAP models 320C, 320B and 112B work more like other FortiAP models with LAN ports. The LAN port can be

- bridged to the incoming WAN interface
- bridged to one of the WiFi SSIDs that the FortiAP unit carries
- connected by NAT to the incoming WAN interface

The LAN port is labeled LAN2. The port labeled LAN1 acts as a WAN port connecting the FortiAP to a FortiGate or to FortiCloud. By default, LAN2 is bridged to LAN1. Access to other modes of LAN2 operation must be enabled in the CLI:

```
config wireless-controller wtp-profile
   edit <profile_name>
      set wan-port-mode wan-lan
   end
```

By default `wan-port-mode` is set to `wan-only`.

When `wan-port-mode` is set to `wan-lan`, LAN2 Port options are available in the FortiAP Profile, the same as other FortiAP models with LAN ports, such as 11C and 14C. In the GUI, see the **LAN Port** settings in **Wireless Controller > FortiAP Profiles**. In the CLI, use the `config lan` subcommand of `config wireless-controller wtp-profile`. LAN Port settings can be overridden on individual FortiAPs.

The WAN port can also be configured on the FortiAP's CLI. See FortiAP CLI for more information.

SSID Groups (264010)

SSID groups have SSIDs as members and can be used just like an individual SSID. To create an SSID group go to **WiFi Controller > SSID** and select **Create New > SSID Group**. An SSID can belong to multiple groups.

GUI improvements (205523 278771 278898)

- Managed FortiAP pages now show WTP Mode, either Normal or Remote. WTP Mode is an optional column in the Managed FortiAPs list.
- WIDS Profile is an optional column in the FortiAP Profiles list.
- If a software switch interface contains a SSID (but only one), the WiFi SSID settings are available in the switch interface settings.

CAPWAP Protected Management Frames (PMF) support (244510)

Protected Management Frames protect some types of management frames like deauthorization, disassociation and action frames. This feature, now mandatory on WiFi certified 802.1ac devices, prevents attackers from sending plain deauthorization/disassociation frames to disrupt or tear down a connection/association. PMF is a Wi-Fi Alliance specification based on IEEE 802.11w.

PMF is configurable only in the CLI.

```
config wireless-controller vap
   edit <vap_name>
      set pmf {disable | enable | optional}
      set pmf-assoc-comeback-timeout <integer>
      set pmf-sa-query-retry-timeout <integer>
```

```
        set okc {disable | enable}
    next
end
```

`optional` Enable PMF and allow clients without PMF.

`pmf-assoc-comeback-timeout` Protected Management Frames (PMF) maximum timeout for comeback (1-20 seconds).

`pmf-sa-query-retry-timeout` Protected Management Frames (PMF) sa query retry timeout interval (in 100 ms), from 100 to 500. Integer value from 1 to 5.

`okc` enable or disable Opportunistic Key Caching (OKC).

Opportunistic Key Caching Support (244510)

To facilitate faster roaming client roaming, you can enable Opportunistic Key Caching (OKC) on your WiFi network. When a client associates with an AP, its PMK identifier is sent to all other APs on the network. This eliminates the need for an already-authenticated client to repeat the full EAP exchange process when it roams to another AP on the same network.

OKC is configurable only in the CLI.

```
config wireless-controller vap
    edit <vap_name>
        set okc {disable | enable}
    next
end
```

FortiPresence push REST API (273954)

When the FortiGate is located on a private IP network, the FortiPresence server cannot poll the FortiGate for information. Instead, the FortiGate must be configured to push the information to the FortiPresence server.

The configuration parameters are:

fortipresence-server	FortiPresence server IP address
fortipresence-port	FortiPresence server UDP listening port (the default is 3000)
fortipresence-secret	FortiPresence secret password (8 characters maximum)
fortipresence-project	FortiPresence project name (16 characters maximum)
fortipresence-frequency	FortiPresence report transmit frequency (Range 5 to 65535 seconds. Default = 30)
fortipresence-rogue	Enable/disable FortiPresence reporting of Rogue APs
fortipresence-unassoc	Enable/disable FortiPresence reporting of unassociated devices

For example,

```
config wireless-controller wtp-profile
    edit "FP223B-GuestWiFi"
        config lbs
            set fortipresence enable
            set fortipresence-server 10.10.0.1
            set fortipresence-port 3000
```

```
            set fortipresence-secret "hardtoguess"
            set fortipresence-project fortipresence
            set fortipresence-frequency 30
            set fortipresence-rogue : disable
            set fortipresence-unassoc: disable
         end
```

More detailed information will be provided in FortiPresence documentation.

GUI support for WiFi SSID schedules (276425 269695 269668)

WiFi SSIDs include a schedule that determines when the WiFi network is available. The default schedule is Always. You can choose any schedule (but not schedule group) that is defined in **Policy & Objects > Objects > Schedules**.

CLI Syntax

```
config wireless-controller vap
   edit vap-name
      set schedule always
   end
```

The WiFi SSID list includes a Schedule column.

SSID Groups

An SSID Group has SSIDs as members and can be specified in any field that accepts an SSID.

To create an SSID Group in the GUI, go to **WiFi Controller > SSID** and select **Create New > SSID Group**. Give the group a **Name** and choose **Members** (SSIDs, but not SSID Groups).

To create an SSID Group in the CLI:

```
config wireless-controller vap-group
   edit vap-group-name
      set vaps "ssid1" "ssid2"
   end
```

RADIUS Change of Authorization (CoA) support

The CoA feature enables the FortiGate to receive a client disconnect message from the RADIUS server. This is used to disconnect clients when their time, credit or bandwidth had been used up. Enable this on the RADIUS server using the CLI:

```
config user radius
   edit <server_name>
      set radius-coa enable
   end
```

CAPWAP offloading to NPU

On FortiGates with the NP6 processor, offloading of CAPWAP traffic to the NP6 is enabled by default.

Administrative access to managed FortiAPs

By default, telnet access to a FortiAP unit's internal configuration is disabled when the FortiAP is managed (has been authorized) by a FortiGate. You can enable administrative access in the FortiAP profile, like this:

```
config wireless-controller wtp-profile
   edit FAP321C-default
      set allowaccess telnet
   end
```

The `allowaccess` field also accepts `http` to allow HTTP administatrative access.

The FortiAP Profile allowaccess settings can be overridden at the individual FortiAP:

```
config wireless-controller wtp
   edit FP321CX14004706
      set override-allowaccess enable
      set allowaccess telnet http
   end
```

Improved monitoring

The **WiFi Client Monitor** under **Monitor** displays top wireless user network usage and information that includes Device, Source IP, Source SSID, and Access Point. Disk logging must be enabled.

Wifi Clients and **Failed Authentication** views under **FortiView** are historical views.

Chapter 2 - Getting Started

- Installation discusses installing a FortiGate in your network.
- Using the GUI describes how to use the graphical user interface (GUI).
- Using the CLI provides an overview of the command line interface (CLI) for FortiOS. If you are new to the FortiOS CLI, this section provides a high level overview of how to use this method of administration.
- FortiGate Inspection Mode summarizes proxy-based and flow-based inspection modes.
- Fortigate LED Specifications presents a short guide to LED status indicators.
- introduces you to FortiGate models 30-90, also known as the Entry Level models.
- Basic Administration explains basic tasks for setting up a new FortiGate.
- Next Steps lists resources available to help you with more advanced FortiGate configurations.

Differences between Models

Before you get started, note that not all FortiGate models have the same features. This is especially true of the desktop or entry-level models: FortiGate / FortiWiFi models 30 to 90. If you are using one of these FortiGate models, you may have some difficulties accessing certain features. Preliminary information on entry-level models is available below. Consult your model's Quick Start Guide or hardware manual for further details.

Additionally, Fortinet's Cookbook site has a section on hardware that provides how-to recipes and articles on features that are unique to certain models.

Users should know that FortiGate models differ principally by the names used and the features available.

Entry-level models

The entry-level, or desktop, models can connect to the internet in two simple steps. They also have a number of features that are only available using the CLI, rather than appearing in the GUI.

- Quick installation using DHCP
- CLI-only features

Names

Naming conventions may vary between FortiGate models. For example, on some models the hardware switch interface used for the local area network is called **lan**, while on other units it is called **internal**.

Features

Certain features are not available on all models. Additionally, a particular feature may be available only through the CLI on some models, while that same feature may be viewed in the GUI on other models.

If you believe your FortiGate model supports a feature that does not appear in the GUI, go to **System > Feature Select** and confirm that the feature is enabled. For more information, see Feature Select on page 259.

For more information about features that vary by model, please see the Feature / Platform Matrix.

Quick installation using DHCP

Most of the FortiGate desktop models have a default configuration that includes a DHCP server on the **lan** (or **internal**) interface and a security policy that securely allows all sessions from the Internal network to reach the Internet. Because of this, you can connect your desktop FortiGate to the Internet in two simple steps.

In order to use this installation method, your ISP must provide connectivity with DHCP and accept DHCP requests without authentication. You must also be using IPv4 to connect your FortiGate to the Internet.

1. Connect the FortiGate's **wan** interface to your ISP-supplied equipment, and then connect the internal network to the FortiGate's default **lan** interface. Turn on the ISP's equipment, the FortiGate, and the PCs on the internal network.
2. (Windows Vista/7/8/10 users) Go to **Network and Sharing Center** and select **Local Area Connections**. Select **Properties**. Select **Internet Protocol Version 4 (TCP/IPv4)**, then select **Properties**. Select **Obtain an IP address automatically** and **Obtain DNS server address automatically**.

   (Mac OS X users) Go to **Network Preferences** and select **Ethernet**. Set **Configure IPv4 to Using DHCP**.

Results

From any PC on the internal network, open a web browser and browse to any website. You can successfully connect to the Internet.

CLI-only features

As you can see in the Feature / Platform Matrix, the entry level models have a number of features that are only available using the Command Line Interface (CLI), rather than appearing in the GUI.

You can use FortiExplorer or terminal emulation software to access the CLI. The CLI can also be assessed from within the GUI, by going to the **Dashboard** and using the **CLI Console** widget. If the console does not appear in the dashboard, select **Widget**, then select **CLI Console**. The console can also be accessed by using the drop-down menu in the top right of the page, where your account's user name is shown.

You can also open the CLI console so that it automatically opens to the object you wish to configure. For example, to edit a firewall policy, right-click on the policy in the list (**Policy & Objects > IPv4 Policy**) and select **Edit in CLI**. The CLI console will appear, with the commands to access this part of the configuration added automatically.

Once you have access to the CLI, you can enter instructions for specific tasks that can be found throughout the FortiOS Handbook. You can also refer to the CLI Reference for a list of the available commands.

Installation

This section discusses how to install your FortiGate and use it in your network, after completion of the initial set-up outlined in the FortiGate model's Quick Start Guide. The section also provides troubleshooting tips.

The following topics are included in this section:

- NAT/Route Mode vs. Transparent Mode
- Setup Wizard
- Installing a FortiGate in NAT/Route mode
- Using a Virtual Wire Pair
- Troubleshooting your FortiGate Installation

NAT/Route Mode vs. Transparent Mode

A FortiGate can operate in one of two modes: NAT/Route or Transparent.

In NAT/Route mode, the most common operating mode, a FortiGate is installed as a gateway or router between two networks. In most cases, it is used between a private network and the Internet. This allows the FortiGate to hide the IP addresses of the private network using network address translation (NAT). NAT/Route mode is also used when two or more Internet service providers (ISPs) will provide the FortiGate with redundant Internet connections.

A FortiGate in Transparent mode is installed between the internal network and the router. In this mode, the FortiGate does not make any changes to IP addresses and only applies security scanning to traffic. When a FortiGate is added to a network in Transparent mode, no network changes are required, except to provide the FortiGate with a management IP address. Transparent mode is used primarily when there is a need to increase network protection but changing the configuration of the network itself is impractical.

For more information about Transparent Mode, see the Transparent Mode handbook.

Setup Wizard

The Setup Wizard helps to quickly configure your FortiGate to allow Internet access and remote access. The wizard can be launched from the GUI by selecting the button, located in the top right corner. You can also get to the Setup Wizard through FortiExplorer which can be downloaded for either Windows or Mac OS at www.fortinet.com.

Using the Setup Wizard

The Setup Wizard is intended to be used for initial setup. If it is used on a previously configured FortiGate, it replaces parts of the configuration, including existing firewall policies.

1. Connect to the FortiGate using FortiExplorer. It is recommended to view FortiExplorer in fullscreen mode because some options may not be visible otherwise.
2. Select your FortiGate, then select **Setup Wizard**.
3. Login using an admin account (the default admin account has the username `admin` and no password).
4. Select **Change Password** to set a new password for the admin account. Select **Next**.
5. Select the appropriate time zone. Select **Next**.
6. Fill in the appropriate information about your **Internet WAN Connection**. Select **Next**.
7. Enter an **IP Address** and **Netmask** for your LAN. If necessary, enable **DHCP** and select a **Start** and **End Address**. Select **Next**.
8. Select the schedule for when Internet access should be allowed. Select **Next**.
9. Select the appropriate options for your **Internet Access Policy**, including **NAT** options and **Unified Threat Management**. Select **Next**.
10. If necessary, configure options to allow **Remote VPN Access** using either an SSL VPN or an IPsec VPN. Select **Next**.
11. A summary screen will appear. If the configuration shown is correct, select **Configure**.
12. (Optional) If you wish to activate a FortiCloud account, select **Next** and enter your information (for more information about FortiCloud, see the FortiCloud FAQ). Otherwise, select **Done**.

Results

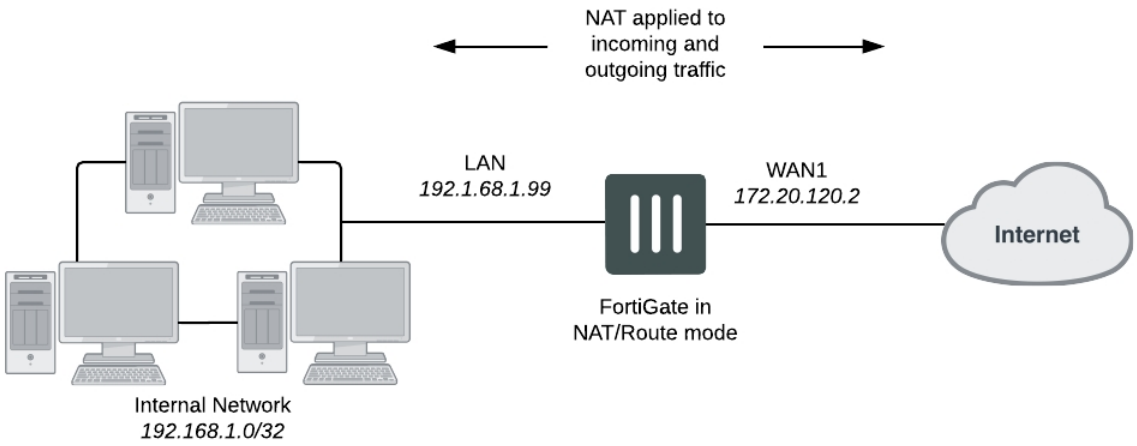
Your configuration has now been set up on the FortiGate allowing users on the LAN to have Internet access.

Installing a FortiGate in NAT/Route mode

There are two main ways to install a FortiGate using NAT/Route mode: Standard Installation in NAT/Route Mode, where Internet access is provided by a single ISP, and Redundant Internet Installation, where two ISPs are used.

Standard Installation in NAT/Route Mode

In this configuration, a FortiGate is installed as a gateway or router between a private network and the Internet. By using network address translation (NAT), the FortiGate is able to hide the IP addresses of the private network.



Installing a FortiGate in NAT/Route Mode

1. Connect the FortiGate's Internet-facing interface (typically WAN1) to your ISP-supplied equipment.
2. Connect a PC to the FortiGate using an internal port (typically port 1).
3. Power on the ISP's equipment, the FortiGate, and the PC on the internal network.
4. From the PC on the internal network, connect to the FortiGate's GUI using either FortiExplorer or an Internet browser (for information about connecting to the GUI, please see your models QuickStart Guide). Login using an admin account (the default admin account has the username `admin` and no password).
5. Go to **Network > Interfaces** and edit the Internet-facing interface. Set **Addressing Mode** to **Manual** and the **IP/Netmask** to your public IP address. Select **OK**.

If you have ISP equipment between your FortiGate and the Internet (for example, a router), then the wan1 IP will also use a private IP assigned by the ISP equipment. If this equipment uses DHCP, set **Addressing Mode** to **DHCP** to get an IP assigned to the interface.

If the ISP equipment does not use DHCP, your ISP can provide you with the correct private IP to use for the interface.

6. Edit the **lan** interface (called **internal** on some FortiGate models). Make sure the interface's **Role** is set to **LAN**. Set **Addressing Mode** to **Manual** and set the **IP/Netmask** to the private IP address you wish to use for the FortiGate. Select **OK**.
7. Go to **Network > Static Routes** and select **Create New** to add a default route. Set **Destination** to **Subnet** (which allows you to input a numeric IP address or subnet), **Destination IP/Mask** to 0.0.0.0/0.0.0.0, **Device** to the Internet-facing interface, and **Gateway** to the gateway (or default route) provided by your ISP or to the next hop router, depending on your network requirements. Select **OK**.

A default route always has a Destination IP/Mask of 0.0.0.0/0.0.0.0. Normally, you would have only one default route. If the static route list already contains a default route, you can either edit it or delete it and add a new one.

8. (Optional) The FortiGate's DNS Settings are set to use FortiGuard DNS servers by default, which is sufficient for most networks. However, if you need to change the DNS servers, go to **Network > DNS**, select **Specify**, and add **Primary** and **Secondary** DNS servers. Select **Apply**.

Some FortiGate models include an IPv4 security policy allowing access from **LAN/Internal** to **WAN/WAN1** in the default configuration. This policy can be found at **Policy & Objects > IPv4 Policy**.

If you have one of these models, users are now able to access the Internet.

9. Go to **Policy & Objects > IPv4 Policy** and select **Create New** to add a security policy that allows users on the private network to access the Internet.

If your network uses IPv6 addresses, go to **Policy & Objects > IPv6 Policy**and select **Create New** to add a security policy that allows users on the private network to access the Internet. If the IPv6 menu option is not available, go to **System > Feature Select**, turn on **IPv6**, and select **Apply**. For more information on IPv6 networks, see the IPv6 Handbook.

10. In the policy, set the **Incoming Interface** to **lan** and the **Outgoing Interface** to the Internet-facing interface. You will also need to set **Source**, **Destination Address**, **Schedule**, and **Service** according to your network requirements. You can set these fields to the default all/ANY settings for now but should create the appropriate objects later after the policies have been verified. Make sure the **Action** is set to **ACCEPT**. Turn on **NAT** and make sure **Use Outgoing Interface Address** is selected. Select **OK**.

It is recommended to avoid using any security profiles, such as AntiVirus or Web Filter, until after you have successfully installed the FortiGate. After the installation is verified, you can apply any required security profiles.

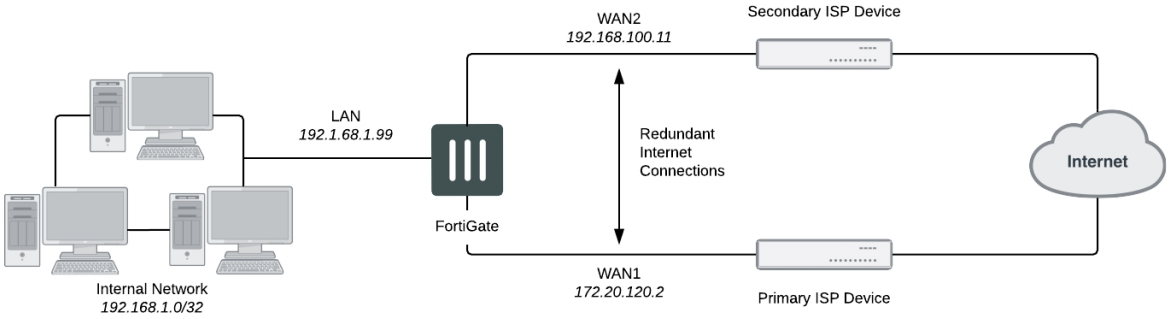
For more information about using security profiles, see the Security Profiles handbook.

Results

Users on the internal network are now able to access the Internet. They should also be able to connect to the Internet using any other protocol or connection method that you defined in the security policy.

Redundant Internet Installation

In this configuration, a WAN link interface is created providing the FortiGate with redundant Internet connections from two Internet service providers (ISPs). The WAN link interface combines these two connections, allowing the FortiGate to treat them as a single interface.



Installing a FortiGate with Redundant Internet

If you have previously configured your FortiGate using the standard installation, you will have to delete all routes and policies referring to an interface that will be used to provide redundant Internet. This includes the default Internet access policy that is included on many FortiGate models.

1. Connect the FortiGate's Internet-facing interfaces (typically WAN1 and WAN2) to your ISP-supplied equipment.
2. Go to **Network > WAN LLB** to create a WAN link interface, which is used to group multiple Internet connections together so that the FortiGate can treat them as a single interface.
3. Select an appropriate method of **WAN Load Balancing** from the following options:
   - **Source IP based** - The next hop is based on the traffic's source IP address.
   - **Weighted Round Robin** - Weight is input for all the active members of the WAN link.
   - **Spill-over** - A traffic cap is defined for active members; when it is exceeded, the traffic will automatically activate the standby link.

- **Source-Destination IP based** - The next hop is based on both the traffic's source and destination IP address.
- **Measured-Volume based**- A volume ratio is set for each active member of the WAN link.

4. Add your Internet-facing interfaces to the WAN link interface and configure load balancing as required for each interface.
5. Go to **Network > Static Routes** and create a new default route. Set **Device** to the virtual WAN link.
6. Go to **Policy & Objects > IPv4 Policy** and select **Create New** to add a security policy that allows users on the private network to access the Internet.

If your network uses IPv6 addresses, go to **Policy & Objects > IPv6 Policy** and select **Create New** to add a security policy that allows users on the private network to access the Internet. If the IPv6 menu option is not available, go to **System > Feature Select**, turn on **IPv6**, and select **Apply**. For more information on IPv6 networks, see the IPv6 Handbook.

4. In the policy, set the **Incoming Interface** to the internal interface and the **Outgoing Interface** to the WAN link interface. You will also need to set **Source Address**, **Destination Address**, **Schedule**, and **Service** according to your network requirements. You can set these fields to the default all/ANY settings for now but should create the appropriate objects later after the policies have been verified.
5. Make sure the **Action** is set to **ACCEPT**. Turn on **NAT** and make sure **Use Destination Interface Address** is selected. Select **OK**.

It is recommended to avoid using any security profiles, such as AntiVirus or Web Filter, until after you have successfully installed the FortiGate. After the installation is verified, you can apply any required security profiles.

For more information about using security profiles, see the Security Profiles handbook.

Results

Users on the internal network are now able to browse the Internet. They should also be able to connect to the Internet using any other protocol or connection method defined in the security policy.

The amount of traffic an individual member of the WAN link interface will use will depend on the load balancing method selected. You can view this usage by going to **FortiView > All Sessions** and viewing the **Destination Interface** column. If this column is not shown, right-click on the title row and select **Destination Interface** from the dropdown menu. Scroll to the bottom of the menu and select **Apply**.

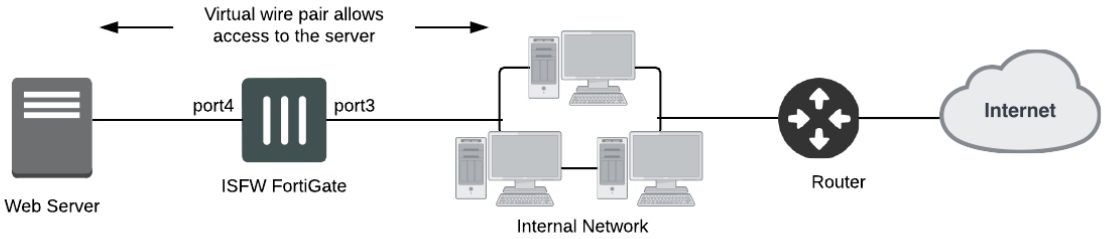
Using a Virtual Wire Pair

A virtual wire pair consists of two interfaces that have no IP addressing and are treated similar to a transparent mode VDOM. All traffic received by one interface in the virtual wire pair can only be forwarded out the other interface, provided that a virtual wire pair firewall policy allows this traffic. Traffic from other interfaces cannot be routed to the interfaces in a virtual wire pair.

Virtual wire pairs are useful for unusual topologies where MAC addresses do not behave normally: for example, port pairing can be used in a Direct Server Return (DSR) topology where the response MAC address pair may not match the request's MAC address pair.

In FortiOS 5.4, virtual wire pairing replaces the port pairing feature available in earlier firmware versions. Unlike port pairing, virtual wire pairing can be used for FortiGates in both NAT/Route and Transparent modes.

In the example configuration below, a virtual wire pair (consisting of port3 and port4) makes it easier to protect a web server that is behind a FortiGate operating as an Internal Segmentation Firewall (ISFW). Users on the internal network will access the web server through the ISFW over the virtual wire pair.



Adding a virtual wire pair and virtual wire pair policy

Interfaces used in a virtual wire pair cannot be used to access the ISFW FortiGate. Before creating a virtual wire pair, make sure you have a different port configured to allow admin access using your preferred protocol.

1. Go to **Network > Interfaces** and select **Create New > Virtual Wire Pair**.
2. Select the interfaces to add to the virtual wire pair. These interfaces cannot be part of a switch, such as the default **lan/internal** interface.
3. (Optional) If desired, enable **Wildcard VLAN**.
4. Select **OK**.
5. Go to **Policy & Objects > IPv4 Virtual Wire Pair Policy**, select the virtual wire pair, and select **Create New**.
6. Select the direction that traffic is allowed to flow.
7. Configure the other firewall options as desired.
8. Select **OK** .
9. If necessary, create a second virtual wire pair policy to allow traffic to flow in the opposite direction.

If you have a USB-wan interface, it will not be included in the interface list when building a wired-pair.

Results

Traffic can now flow through the FortiGate using the virtual wire pair.

For more information on this feature in FortiOS 5.4.0 and FortiOS 5.4.1, see "Virtual Wire Pair " on page 110 in the What's New chapter.

Troubleshooting your FortiGate Installation

If your FortiGate does not function as desired after installation, try the following troubleshooting tips:

1. **Use FortiExplorer if you can't connect to the FortiGate over Ethernet.**
   If you can't connect to the FortiGate GUI or CLI, you may be able to connect using FortiExplorer. See your FortiGate's Quick Start Guidefor details.
2. **Check for equipment issues.**
   Verify that all network equipment is powered on and operating as expected. Refer to the QuickStart Guide for information about connecting your FortiGate to the network. You will also find detailed information about the FortiGate LED indicators.
3. **Check the physical network connections.**
   Check the cables used for all physical connections to ensure that they are fully connected and do not appear damaged, and make sure that each cable connects to the correct device and the correct Ethernet port on that device.
   Also, check the **Unit Operation** widget, found in the **Dashboard**, to make sure the ports used in the connections are shown in green.
4. **Verify that you can connect to the internal IP address of the FortiGate.**
   Connect to the GUI from the FortiGate's internal interface by browsing to its IP address. From the PC, try to ping the internal interface IP address; for example, `ping 192.168.1.99`.
   If you cannot connect to the internal interface, verify the IP configuration of the PC. If you can ping the interface but can't connect to the GUI, check the settings for administrative access on that interface.
5. **Check the FortiGate interface configurations.**
   Check the configuration of the FortiGate interface connected to the internal network, and check the configuration of the FortiGate interface that connects to the Internet to make sure **Addressing Mode** is set to the correct mode.
6. **Verify the security policy configuration.**
   Go to **Policy & Objects > IPv4 Policy** and verify that the internal interface to Internet-facing interface security policy has been added and is located near the top of the policy list. Check the **Sessions** column to ensure that traffic has been processed (if this column does not appear, right-click on the title row, select **Sessions**, and select **Apply**).
   If you are using NAT/Route mode, check the configuration of the policy to make sure that **NAT** is turned on and that **Use Outgoing Interface Address** is selected.
7. **Verify that you can connect to the Internet-facing interface's IP address.**
   Ping the IP address of the FortiGate's Internet-facing interface. If you cannot connect to the interface, the FortiGate is not allowing sessions from the internal interface to Internet-facing interface.
8. **Verify the static routing configuration.**
   Go to **Network > Static Routes** and verify that the default route is correct. Go to **Monitor > Routing Monitor** and verify that the default route appears in the list as a static route. Along with the default route, you should see two routes shown as **Connected**, one for each connected FortiGate interface.
9. **Verify that you can connect to the gateway provided by your ISP.**
   Ping the default gateway IP address from a PC on the internal network. If you cannot reach the gateway, contact your ISP to verify that you are using the correct gateway.
10. **Verify that you can communicate from the FortiGate to the Internet.**
    Access the FortiGate CLI and use the command `execute ping8.8.8.8`. You can also use the `execute traceroute 8.8.8.8` command to troubleshoot connectivity to the Internet.
11. **Verify the DNS configurations of the FortiGate and the PCs.**
    Check for DNS errors by pinging or using traceroute to connect to a domain name; for example: `ping`

`www.fortinet.com`
If the name cannot be resolved, the FortiGate or PC cannot connect to a DNS server and you should confirm that the DNS server IP addresses are present and correct.

12. **Confirm that the FortiGate can connect to the FortiGuard network.**
Once registered, the FortiGate obtains AntiVirus and Application Control and other updates from the FortiGuard network. Once the FortiGate is on your network, you should confirm that it can reach the FortiGuard network.
First, check the **License Information** widget to make sure that the status of all FortiGuard services matches the services that you have purchased.
Go to **System > FortiGuard**. Expand **Web Filtering and Email Filtering Options** and select **Test Availability**. After a minute, the GUI should indicate a successful connection.
13. **Consider changing the MAC address of your external interface.**
Some ISPs do not want the MAC address of the device connecting to their network cable to change. If you have added a FortiGate to your network, you may have to change the MAC address of the Internet-facing interface using the following CLI command:

```
config system interface
   edit <interface>
      set macaddr <xx:xx:xx:xx:xx:xx>
   end
end
```

14. Either reset the FortiGate to factory defaults or contact the technical assistance center.
If all else fails, reset the FortiGate to factory defaults using the CLI command `execute factoryreset`. When prompted, type `y` to confirm the reset.

You can also contact Fortinet Support for assistance. Read the following article found on the Fortinet Cookbook website: How to work with Fortinet Support to understand what type of support is available and to determine which level of support is right for you. For further information, go to support.fortinet.com.

Using the GUI

This section presents an introduction to the FortiGate's graphical user interface (GUI), also called the web-based manager. You will also find information you can access from the various dashboards and tables.

The following topics are included in this section:

- Connecting to the GUI
- Menus
- Dashboard
- Feature Select
- Tables
- Text Strings

More information on features available through the GUI in FortiOS 5.4 can be found in the What's New chapter of the FortiOS™ Handbook under GUI Refresh.

Connecting to the GUI

After completing your FortiGate's initial installation, there are two ways to connect to the GUI: using FortiExplorer or a web browser.

FortiExplorer

To connect to the GUI using FortiExplorer, connect your management computer to your FortiGate's USB management port, using the cable that came with the unit. FortiExplorer should open automatically once the devices are connected; if it does not, open the program manually.

To connect to the GUI, go to **Devices > Web-based Manager** and enter your user name and password. If you have not changed the admin account's password, use the default user name, `admin`, and leave the password field blank.

The GUI will now be displayed in FortiExplorer.

Web browser

The recommended minimum screen resolution for properly displaying the GUI is 1280 by 1024. Check the FortiOS Release Notes for information about browser compatibility.

In order to connect to the GUI using a web browser, an interface must be configured to allow administrative access over HTTPS or over both HTTPS and HTTP. By default, an interface has already been set up that allows HTTPS access, with the IP address 192.168.1.99.

Browse to https://192.168.1.99 and enter your user name and password. If you have not changed the admin account's password, use the default user name, `admin`, and leave the password field blank.

The GUI will now be displayed in your browser.

If you wish to use a different interface to access the GUI, do the following:

1. Go to **Network > Interfaces** and edit the interface you wish to use for access. Take note of its assigned IP address.
2. Beside **Administrative Access**, select **HTTPS**. You can also select **HTTP**, although this is not recommended as the connection will be less secure.
3. Select **OK**.
4. Browse to the IP address using your chosen protocol.

Results

The GUI will now be displayed in your browser.

More information on features available through the GUI in FortiOS 5.4 can be found in the What's New chapter of the FortiOS™ Handbook under GUI Refresh.

Menus

If there is a menu you believe your FortiGate model supports that does not appear in the GUI as expected, go to **System > Feature Select**and ensure the feature is enabled. For more information, see "Feature Select" on page 259.

The GUI contains the following main menus, which provide access to configuration options for most FortiOS features:

Dashboard	The dashboard displays various widgets that display important system information and allow you to configure some system options. For more information, see "Dashboard" on page 251.
FortiView	A collection of dashboards and logs that give insight into network traffic traffic, showing which users are creating the most traffic, but what sort of traffic it is, when the traffic occurs, and what kind of threat the traffic may pose to the network. For more information, see the FortiView handbook.
Network	Options for networking, including configuring system interfaces and routing options.
System	Configure system settings, such as administrators, FortiGuard, and certificates.
Policy & Objects	Configure firewall policies, protocol options, and supporting content for policies, including schedules, firewall addresses, and traffic shapers.
Security Profiles	Configure your FortiGate's security features, including AntiVirus, Web Filtering, and Application Control.
VPN	Configure options for IPsec and SSL virtual private networks (VPNs).
User & Device	Configure user accounts, groups, and authentication methods, including external authentication and single sign-on (SSO).
WAN Opt. & Cache	Configure WAN optimization and web caching to improve performance and security of traffic passing between locations on your wide area network (WAN) or from the Internet to your web servers. This menu only appears on FortiGate models that support this feature. For more information, see the WAN Optimization, Web Cache, Explicit Proxy, and WCCP handbook.

WiFi & Switch Controller	Configure the unit to act as a wireless network controller, managing the wireless Access Point (AP) functionality of FortiWiFi and FortiAP units. On certain FortiGate models, this menu is called **WiFi & Switch Controller** and has additional features allowing for FortiSwitch units to be managed by the FortiGate.
Log & Report	Configure logging and alert email as well as reports.
Monitor	View a variety of monitors, including the Routing Monitor, VPN monitors for both IPsec and SSL, and monitors relating to wireless networking.

Dashboard

The Dashboard consists of a number of widgets, each displaying a different set of information. A number of pre-configured widgets are available which can be customized to meet your needs.

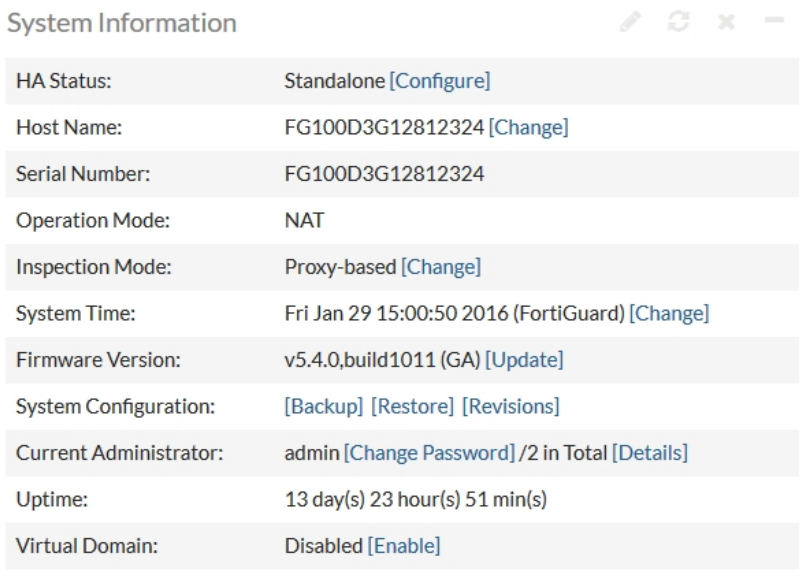
To choose which widgets will be shown, select **+ Widget** (located in the bottom left corner) and select the widget you wish to view, which will add it to the dashboard. Widgets can be rearranged for easier access and viewing.

Some display options are available each widget, that can be accessed by selecting the button.

The Dashboard contains the following widgets:

- System Information
- License Information
- CLI Console
- System Resources
- Alert Message Console
- Unit Operation
- Advanced Threat Protection Statistics
- Interface History
- USB Modem
- RAID monitor widget

System Information

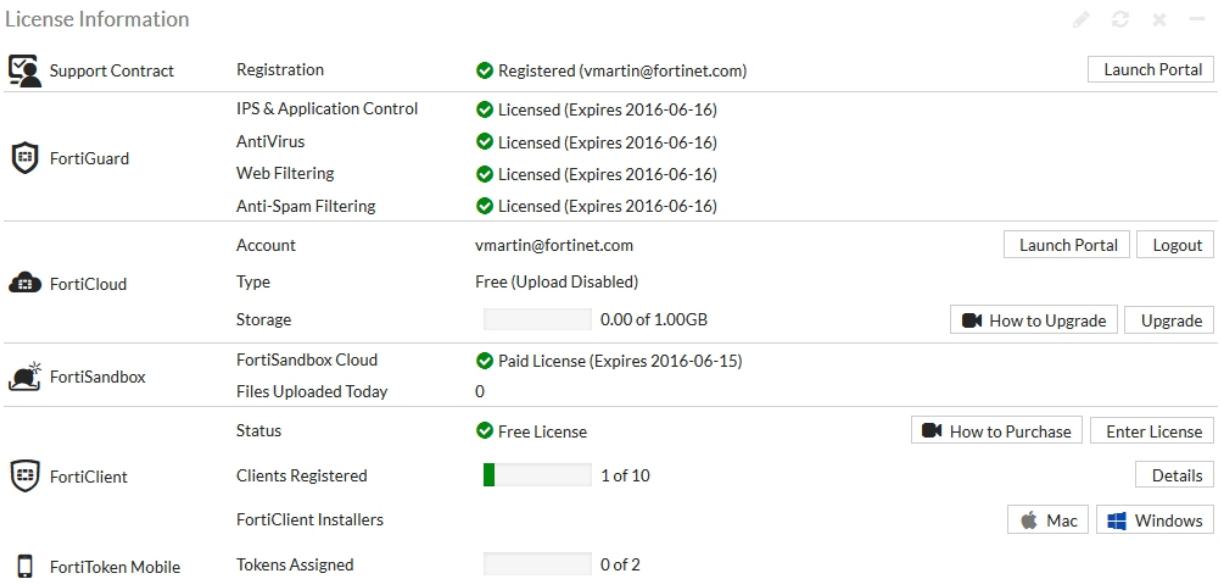


The **System Information** widget shows status information on the FortiGate. Some configuration details / modes can be changed through the widget.

HA Status	The status of High Availability (HA) within the cluster. Standalone indicates the FortiGate is not operating in HA mode. Active-Passive or Active-Active indicate the FortiGate is operating in HA mode. Select **Configure**, to change the HA configuration. For more information, see the High Availability handbook.
Host Name	The name of the FortiGate. By default, the host name is the FortiGate's serial number. If the FortiGate is in HA mode, this information is not displayed.
Serial Number	The serial number of the FortiGate. The serial number is specific to that FortiGate and does not change with firmware upgrades.
Operation Mode	The current operating mode of the FortiGate (a FortiGate can operate in NAT mode or Transparent mode). If virtual domains are enabled, this field shows the operating mode of the current virtual domain. The Global System Status dashboard does not include this information.
Cluster Name	The name of the HA cluster for this FortiGate. The FortiGate must be operating in HA mode to display this field.
Cluster Members	The FortiGates in the HA cluster. Information displayed about each member includes host name, serial number, and whether the FortiGate is a primary (master) or subordinate (slave) FortiGate in the cluster. The FortiGate must be operating in HA mode with virtual domains disabled to display this information.
Virtual Cluster 1 **Virtual Cluster 2**	The role of each FortiGate in virtual cluster 1 and virtual cluster 2. The FortiGate must be operating in HA mode with virtual domains enabled to display this information.
System Time	The current date and time.
Firmware Version	The version of the current firmware installed on the FortiGate. You can access the Firmware Management menu by selecting **Update**. For more information, see Firmware.
System Configuration	Using the widget, you can **Backup** the current configuration and **Restore** an older configuration. You can also view configuration changes by selecting **Revisions**.
Current Administrator	The number of administrators currently logged into the FortiGate. Select **Details** to view more information about each administrator that is currently logged in

Uptime	The time in days, hours, and minutes since the FortiGate was started or rebooted.
Virtual Domain	This shows if Virtual Domains (VDOMs) have been enabled on this unit.
Explicit Proxy	Information about he status of the explicit proxy. This information will only appear when this feature is in use. For more information, see the WAN Optimization, Web Cache, Explicit Proxy, and WCCP handbook.
Load Balance	Information about load balancing. This information will only appear when this feature is in use. For more information, see the Load Balancing handbook.

License Information



The **License Information** widget displays the status of your technical support contract, FortiGuard subscriptions, FortiCloud account, and other licenses.

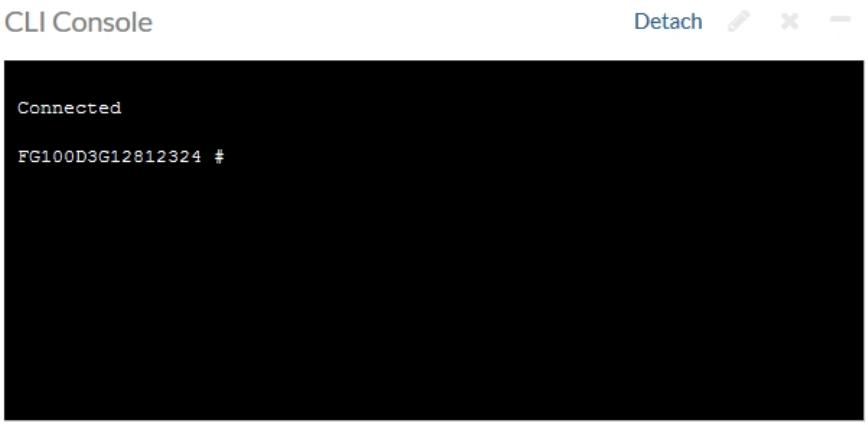
When a new FortiGate is powered on, it automatically searches for FortiGuard services. If the FortiGate is configured for central management, it will look for FortiGuard services on the configured FortiManager system. The FortiGate sends its serial number to the FortiGuard service provider, which then determines whether the FortiGate is registered and has valid contracts for FortiGuard subscriptions and FortiCare support services. If the FortiGate is registered and has a valid contract, the **License Information** is updated.

When a license is near to its expiry date, an option to extend it will appear that allows you to add a new license as soon as you buy it.

Support Contract	Displays details about your current Fortinet Support contract. If **Not Registered** appears, select **Register** to register the FortiGate. If **Expired** appears, select **Renew** for information on renewing your technical support contract. Contact your local reseller. If **Registered** appears, the name of the support that registered this FortiGate is also displayed. The various types of contracts that you currently have and the expiry date for each type. You can select **Launch Portal** to log into the Fortinet Support account that registered this FortiGate.
FortiGuard	Displays your current licenses for services from FortiGuard. Select **Extend** or **Renew** to update any of the licenses (these options only appear when a license is expired or close to expiry).
FortiCloud	Displays details about your current FortiCloud subscription. If the **Activate** button appears, select it to either create a new account or add the FortiGate to an existing account. If you have already activated FortiCloud, the name of the **Account** will be listed. Select **Launch Portal** to view your FortiCloud account in a web browser. Information on the current **Type** and **Storage** is also listed. You can select **Upgrade** to change the type of your FortiCloud account. A video is also available for viewing to help with the upgrade process. For more information, see "FortiCloud" on page 319.
FortiSandbox	Displays details about sandboxing with either FortiSandbox Cloud or FortiSandbox Appliance.
FortiClient	Displays FortiClient license details and the number of **Register** and **Allowed** FortiClient users. You can select **Details** for more information about the current FortiClient users. If you do not have a FortiClient license, you can select **Purchase** to buy one. A video is also available to help you with the purchasing process.
FortiToken Mobile	Displays the number of **Assigned** and **Allowed** FortiTokens.
SMS	Displays the number of **Sent** and **Allowed** SMS messages. You can select **Add Messages** to configure a new SMS message. This information will only appear when SMS has been configured.

Virtual Domain	Displays the maximum number of virtual domains the FortiGate supports with the current license. This information only appears if VDOMs have been enabled on the FortiGate. For some FortiGate models, you can select the **Purchase More** link to purchase a license key through Fortinet technical support to increase the maximum number of VDOMs.

CLI Console

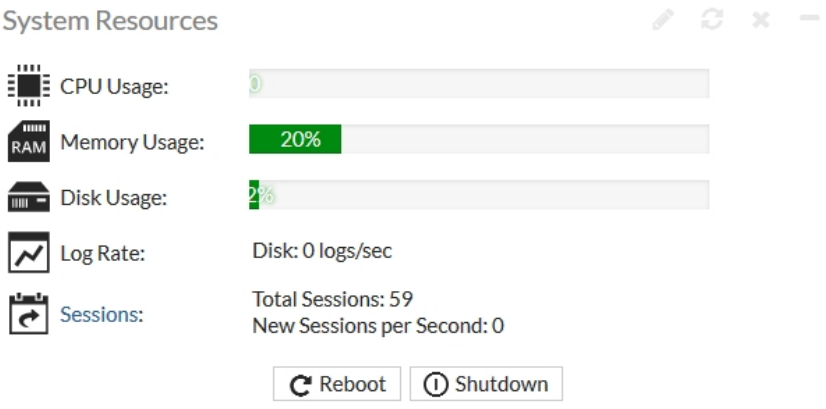


The **CLI Console** widget enables you to access the command line interface (CLI) from the Dashboard.

For ease of use, you can select **Detach** to open the CLI Console widget in a pop-up window that you can re-size and reposition. Select **Attach** to move the widget back into the Dashboard.

For more information, see Using the CLI on page 262 and the CLI Reference Guide.

System Resources

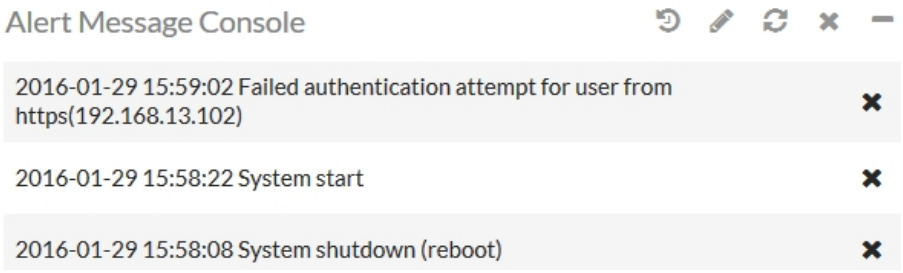


The **System Resources** widget displays basic FortiGate resource usage. This widget displays the information for CPU and memory in either real-time or historical data. For FortiGates with multiple CPUs, you can view the CPU usage as an average of all CPUs or each one individually.

This widget is where you reboot or shutdown the FortiGate.

The options to reboot or shutdown the FortiGate are not available for an admin using the *prof_admin* profile.

Alert Message Console



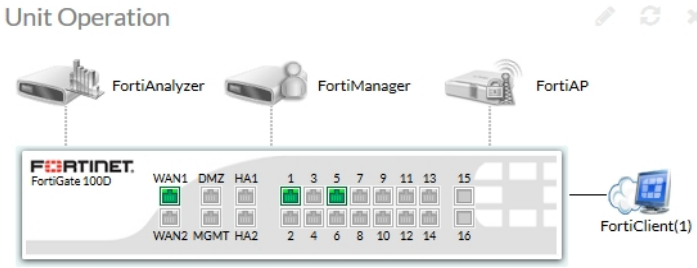
The **Alert Messages Console** widget helps you monitor system events on your FortiGate such as firmware changes, network security events, or virus detection events. Each message shows the date and time that the event occurred.

You can configure the alert message console settings to control what types of messages are displayed on the console.

To configure the Alert Message Console

1. Locate the **Alert Message Console** widget within the **Dashboard**.
2. Select the button.
3. Select the types of alerts that you do not want to be displayed in the widget.
4. Select **OK**.

Unit Operation

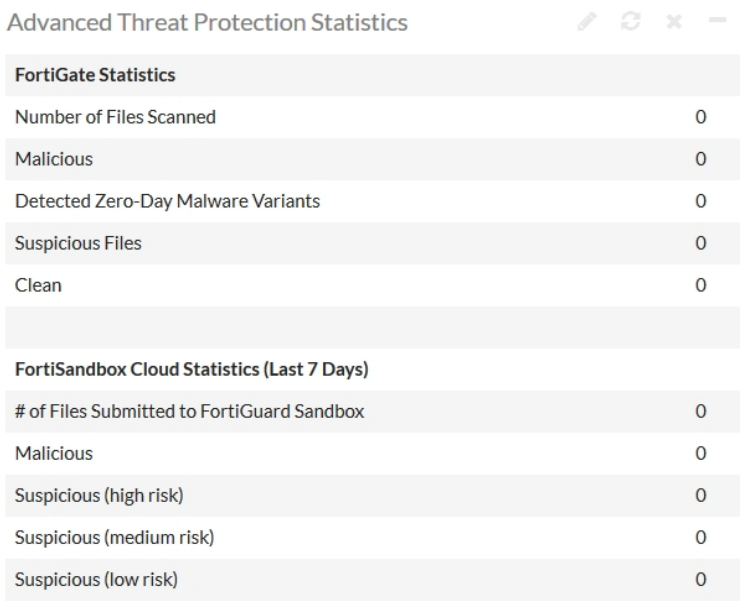


The **Unit Operation** widget is an illustrated version of the FortiGate's front panel that shows the status of the FortiGate's network interfaces. Interfaces appears green when connected. Hover the mouse pointer over an interface to view further details.

Icons around the front panel indicate when the FortiGate is connected to a FortiAnalyzer, FortiManager, or FortiAP. It also shows how many devices running FortiClient are connected to the FortiGate.

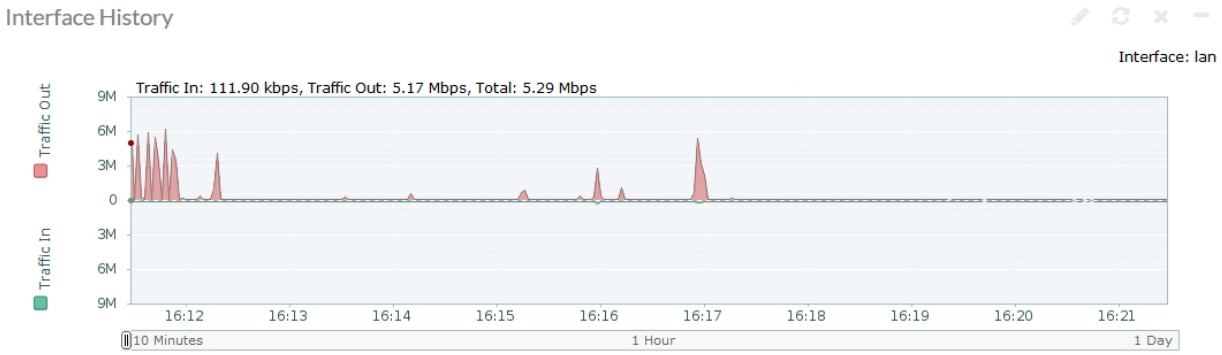
Select the icon in the widget to jump to the configuration page for each device. When connected to one of these devices, a green check mark icon appears next to the icon. If the device communication is configured but the device is unreachable, a red X appears.

Advanced Threat Protection Statistics



The **Advanced Threat Protection Statistics** widget displays a count of detected malware and files scanned for these types of intrusions. If you are using sandboxing with either FortiSandbox Cloud or FortiSandbox Appliance, the widget also displays statics on the number of files sent to FortiSandbox and the sandboxing results.

Interface History



The **Interface History** widget displays the current activity and activity history of a system interface.

The current interface is visible in the top right-hand corner of the widget. You can change the interface that is shown by selecting the button and set **Select Network Interface** to the interface of your choice. You can also select the three time periods that can be viewed in the widget.

USB Modem

If you are using a USB model, this widget enables you to monitor the status of the modem and configure it as needed.

RAID monitor widget

The **RAID Monitor** widget displays the current state of the RAID array and each RAID disk. This widget does not display unless the FortiGate has more than one disk installed and is not available for FortiOS Carrier.

Array status icon	Displays the status of the RAID array. • Green with a check mark shows a healthy RAID array. • Yellow triangle shows the array is in a degraded state but it is still functioning. A degraded array is slower than a healthy array. Rebuild the array to fix the degraded state. • A wrench shows the array is being rebuilt. Positioning the mouse over the array status icon displays a text message of the status of the array.
Disk status icon	There is one icon for each disk in the array. • Green with a check mark shows a healthy disk. • Red with an X shows the disk has failed and needs attention. Positioning the mouse over the disk status icon displays the status of the disk, and the storage capacity of the disk.
RAID Level	The RAID level of this RAID array. The RAID level is set as part of configuring the RAID array.
Status bar	The bar shows the percentage of the RAID array that is currently in use.
Used/Free/Total	Displays the amount of RAID array storage that is being used, the amount of storage that is free, and the total storage in the RAID array. The values are in gigabytes.

Feature Select

Feature Select is used to control which features are visible in the GUI. This allows you to hide features that are not being used. Some features are also disabled by default and must be enabled in order to configure them through the GUI.

Feature Select only alters the visibility of these features, rather than their functionality. For example, disabling web filtering using Feature Select does not remove web filtering from the FortiGate, but removes the option of configuring web filtering from the GUI (configuration options will still be available using the CLI).

Enabling / disabling features

Feature Select can be found at **System > Feature Select**. Once you have accessed Feature Select, ensure all features you wish to use are turned on, and that features you wish to hide are turned off. When you have finished, select **Apply**.

Security Features Presets

The main Security Features can be turned off individually or the five system presets can be used:

- **Full UTM** should be chosen for networks that require full protection from FortiOS. UTM is the default setting.
- **UTM** should be chosen for networks that require protection from external threats and wish to use security features that control network usage.
- **WF** should be chosen for networks that require web filtering.
- **ATP** should be chosen for networks that require protection from viruses and other external threats.
- **NGFW** should be chosen for networks that require application control and protection from external attacks.
- **NGFW + ATP** should be chosen for networks that require protection from external threats and attacks.

Tables

Many of the GUI pages contain tables of information that you can filter to display specific information. Administrators with read and write access can define the filters.

Navigation

Some tables contain information and lists that span multiple pages. At the bottom of the page are the page navigation controls.

Filters

Filters are used to locate a specific set of information or content within multiple pages. These are especially useful in locating specific log entries. The specific filtering options vary, depending on the type of information in the log.

To create a filter, select **Add Filter** at the top of the page. A list of the available fields for filtering will be shown.

Column settings

Column settings are used to select the types of information which are displayed on a certain page. Some pages have a large amounts of information is available and not all content can be displayed on a single screen. Also, some pages may contain content that is not of use to you. Using column settings, you can display only that content which is important to your requirements.

To configure column settings, right-click the header of a column and select the columns you wish to view and de-select any you wish to hide. After you have finished making your selections, select **Apply** (you may need to scroll down the list to do so).

Any changes that you make to the column settings of a list are stored in the unit's configuration and will display the next time that you access the list. To return a page's columns to their default state, select **Reset All Columns**, located at the bottom of the **Column Settings** menu.

Cloning objects

On some tables containing configuration objects, such as the policy table found at **Policy & Objects > IPv4 Policy**, an option appears allowing you to clone an object on the table. This allows you to create a copy of that object, which you can then configure as needed.

To clone an object, first select that object, then right-click to make a menu appear and select **Clone** option.

Editing objects

Some tables allow you to edit parts of the configuration direction on the table's page. For example, security features can be added to an existing firewall policy from the policy list (**Policy & Objects > IPv4 Policy**), by right-clicking the **Security Profiles** column and selecting the appropriate profiles.

If this option is not available, you must select the object, then select the **Edit** option, found at the top of the page.

Text Strings

The configuration of a FortiGate is stored in the FortiOS configuration database. To change the configuration, you can use the GUI or CLI to add, delete, or change configuration settings. These changes are stored in the database as you make them.

Individual settings in the configuration database can be text strings, numeric values, selections from a list of allowed options, or on/off (enable/disable) settings.

Entering text strings (names)

Text strings are used to name entities in the configuration. For example, the name of a firewall address, administrative user, and so on. You can enter any character in a FortiGate configuration text string except, to prevent Cross-Site Scripting (XSS) vulnerabilities, the following characters:

" (double quote), & (ampersand), ' (single quote), < (less than) and > (greater than)

Most GUI text string fields make it easy to add an acceptable number of characters and prevent you from adding the XSS vulnerability characters.

There is a different character limitation for VDOM names and hostnames. For both, the only valid characters are numbers (0-9), letters (a-z, A-Z), and special characters - and _.

From the CLI, you can also use the `tree` command to view the number of characters that are allowed in a name field. For example, firewall address names can contain up to 64 characters. When you add a firewall address to the GUI, you are limited to entering 64 characters in the firewall address name field. From the CLI you can enter the following `tree` command to confirm that the firewall address `name` field allows 64 characters.

```
config firewall address
   tree
   -- [address] --*name (64)
   |- subnet
   |- type
   |- start-ip
   |- end-ip
   |- fqdn (256)
   |- cache-ttl (0,86400)
   |- wildcard
   |- comment (64 xss)
   |- associated-interface (16)
   +- color (0,32)
```

The `tree` command output also shows the number of characters allowed for other firewall address name settings. For example, the fully-qualified domain name (`fqdn`) field can contain up to 256 characters.

Entering numeric values

Numeric values set various sizes, rates, numeric addresses, and other numeric values. For example, a static routing priority of 10, a port number of 8080, or an IP address of 10.10.10.1. Numeric values can be entered as a series of digits without spaces or commas (for example, 10 or 64400), in dotted decimal format (for example the IP address 10.10.10.1) or, as in the case of MAC or IPv6 addresses, separated by colons (for example, the MAC

address 00:09:0F:B7:37:00). Most numeric values are standard base-10 numbers, but some fields (again, such as MAC addresses) require hexadecimal numbers.

Most GUI numeric value fields make it easy to add the acceptable number of digits within the allowed range. CLI help includes information about allowed numeric value ranges. Both the GUI and the CLI prevent you from entering invalid numbers.

Using the CLI

The command line interface (CLI) is an alternative configuration tool to the web-based manager. While the configuration of the GUI uses a point-and-click method, the CLI requires typing commands or uploading batches of commands from a text file, like a configuration script.

This section also explains common CLI tasks that an administrator does on a regular basis and includes the topics:

- Connecting to the CLI
- Command syntax
- Sub-commands
- Permissions
- Tips

Connecting to the CLI

You can access the CLI in three ways:

- Locally with a console cable — Connect your computer directly to the FortiGate unit's console port. Local access is required in some cases:
  - If you are installing your FortiGate unit for the first time and it is not yet configured to connect to your network, you may only be able to connect to the CLI using a local serial console connection, unless you reconfigure your computer's network settings for a peer connection.
  - Restoring the firmware utilizes a boot interrupt. Network access to the CLI is not available until after the boot process has completed, making local CLI access the only viable option.
- Through the network — Connect your computer through any network attached to one of the FortiGate unit's network ports. The network interface must have enabled Telnet or SSH administrative access if you will connect using an SSH/Telnet client, or HTTP/HTTPS administrative access if you will connect using the ***CLI Console*** widget in the web-based manager.
- Locally with FortiExplorer — Connect your computer directly to the FortiGate unit's USB management port. FortiExplorer provides direct access to the FortiOS setup wizard, Web-based Manager, and CLI console.

Connecting to the CLI using a local console

Local console connections to the CLI are formed by directly connecting your management computer or console to the FortiGate unit, using its DB-9 or RJ-45 console port. To connect to the local console you need:

- A computer with an available serial communications (COM) port.
- The RJ-45-to-DB-9 or null modem cable included in your FortiGate package.
- Terminal emulation software such as HyperTerminal for Microsoft Windows.

The following procedure describes connection using Microsoft HyperTerminal software; steps may vary with other terminal emulators.

To connect to the CLI using a local serial console connection

1. Using the null modem or RJ-45-to-DB-9 cable, connect the FortiGate unit's console port to the serial communications (COM) port on your management computer.
2. On your management computer, start HyperTerminal.
3. For the **Connection Description**, enter a **Name** for the connection, and select **OK**.
4. On the **Connect using** drop-down list box, select the communications (COM) port on your management computer you are using to connect to the FortiGate unit.
5. Select **OK**.
6. Select the following **Port** settings and select **OK**.

Bits per second	9600
Data bits	8
Parity	None
Stop bits	1
Flow control	None

7. Press **Enter** or **Return** on your keyboard to connect to the CLI.
8. Type a valid administrator account name (such as `admin`) and press Enter.
9. Type the password for that administrator account and press Enter. (In its default state, there is no password for the `admin` account.)

   The CLI displays the following text:

   ```
   Welcome!
   Type ? to list available commands.
   ```

   You can now enter CLI commands, including configuring access to the CLI through SSH or Telnet.

Enabling access to the CLI through the network (SSH or Telnet)

SSH or Telnet access to the CLI is accomplished by connecting your computer to the FortiGate unit using one of its RJ-45 network ports. You can either connect directly, using a peer connection between the two, or through any intermediary network.

If you do not want to use an SSH/Telnet client and you have access to the web-based manager, you can alternatively access the CLI through the network using the **CLI Console** widget in the web-based manager.

You must enable SSH and/or Telnet on the network interface associated with that physical network port. If your computer is not connected directly or through a switch, you must also configure the FortiGate unit with a static route to a router that can forward packets from the FortiGate unit to your computer. You can do this using either a local console connection or the web-based manager.

Requirements

- A computer with an available serial communications (COM) port and RJ-45 port
- Terminal emulation software such as HyperTerminal for Microsoft Windows
- The RJ-45-to-DB-9 or null modem cable included in your FortiGate package
- A network cable
- Prior configuration of the operating mode, network interface, and static route.

To enable SSH or Telnet access to the CLI using a local console connection

1. Using the network cable, connect the FortiGate unit's network port either directly to your computer's network port, or to a network through which your computer can reach the FortiGate unit.
2. Note the number of the physical network port.
3. Using a local console connection, connect and log into the CLI.
4. Enter the following command:

```
config system interface
   edit <interface_str>
      set allowaccess <protocols_list>
      end
```

   where:

   - `<interface_str>` is the name of the network interface associated with the physical network port and containing its number, such as `port1`
   - `<protocols_list>` is the complete, space-delimited list of permitted administrative access protocols, such as `https ssh telnet`

   For example, to exclude HTTP, HTTPS, SNMP, and PING, and allow only SSH and Telnet administrative access on `port1`:

```
config system interface
   edit port1
      set allowaccess ssh telnet
      end
```

5. To confirm the configuration, enter the command to display the network interface's settings.

```
show system interface <interface_str>
```

   The CLI displays the settings, including the allowed administrative access protocols, for the network interfaces.

Connecting to the CLI using SSH

Once the FortiGate unit is configured to accept SSH connections, you can use an SSH client on your management computer to connect to the CLI.

Secure Shell (SSH) provides both secure authentication and secure communications to the CLI. FortiGate units support 3DES and Blowfish encryption algorithms for SSH.

Before you can connect to the CLI using SSH, you must first configure a network interface to accept SSH connections. The following procedure uses PuTTY. Steps may vary with other SSH clients.

To connect to the CLI using SSH

1. On your management computer, start an SSH client.
2. In **Host Name (or IP Address)**, enter the IP address of a network interface on which you have enabled SSH administrative access.
3. In **Port**, enter `22`.
4. For the **Connection type**, select **SSH**.
5. Select **Open**.
   The SSH client connects to the FortiGate unit.

   The SSH client may display a warning if this is the first time you are connecting to the FortiGate unit and its SSH key is not yet recognized by your SSH client, or if you have previously connected to the FortiGate unit but used a different IP address or SSH key. This is normal If your management computer is directly connected to the FortiGate unit with no network hosts between them.
6. Click **Yes** to verify the fingerprint and accept the FortiGate unit's SSH key. You will not be able to log in until you have accepted the key.
7. The CLI displays a login prompt.
8. Type a valid administrator account name (such as `admin`) and press Enter.
9. Type the password for this administrator account and press Enter.
   The FortiGate unit displays a command prompt (its host name followed by a `#`. You can now enter CLI commands.

If three incorrect login or password attempts occur in a row, you will be disconnected. If this occurs, wait one minute, then reconnect to attempt the login again.

Connecting to the CLI using Telnet

Once the FortiGate unit is configured to accept Telnet connections, you can use a Telnet client on your management computer to connect to the CLI.

Telnet is not a secure access method. SSH should be used to access the CLI from the Internet or any other untrusted network.

Before you can connect to the CLI using Telnet, you must first configure a network interface to accept Telnet connections.

To connect to the CLI using Telnet

1. On your management computer, start a Telnet client.
2. Connect to a FortiGate network interface on which you have enabled Telnet.
3. Type a valid administrator account name (such as `admin`) and press Enter.
4. Type the password for this administrator account and press Enter.
   The FortiGate unit displays a command prompt (its host name followed by a `#`. You can now enter CLI commands.

If three incorrect login or password attempts occur in a row, you will be disconnected. If this occurs, wait one minute, then reconnect to attempt the login again.

Connecting to the CLI locally with FortiExplorer

FortiExplorer is a standalone software solution that allows you to connect to your FortiGate device using the USB interface of your management computer. FortiExplorer provides direct access to the FortiOS setup wizard, Web-based Manager, and CLI console.

FortiExplorer is available for download from the Customer Service & Support web site https://support.fortinet.com in firmware images. FortiExplorer is available for both Microsoft Windows and Mac OS X computers.

FortiExplorer provides a user-friendly tool that you can use to configure a FortiGate unit over a standard USB connection, rather than using a console cable or Ethernet connection.

Do not connect the USB cable until after FortiExplorer has been installed.

Installing FortiExplorer on Microsoft Windows

To install FortiExplorer on a Microsoft Windows workstation:

1. Double-click the .msi or .exe file and follow the instructions on-screen.
2. Connect the USB cable to the FortiGate unit and then to the management computer.
3. The FortiExplorer Fortinet Device Easy Configuration Utility opens when the USB cable is connected. Select **Install the hardware automatically** and select **Next**.
4. After a moment, FortiExplorer will launch.

Installing FortiExplorer on Mac OS X

To install FortiExplorer on a Mac OS X workstation:

1. Double-click the .dmg file and drag the FortiExplorer program file into the Applications folder.
2. Connect the USB cable to the FortiGate unit and then to the management computer.
3. Double-click the FortiExplorer icon to launch the application.

Starting the CLI from FortiExplorer

The below image shows the FortiExplorer tool connected to a FortiGate 100D device, under **Devices**, click on **Command-line Interface** and you will be connected to the CLI:

Command syntax

When entering a command, the command line interface (CLI) requires that you use valid syntax and conform to expected input constraints. It will reject invalid commands.

Fortinet documentation uses the conventions below to describe valid command syntax.

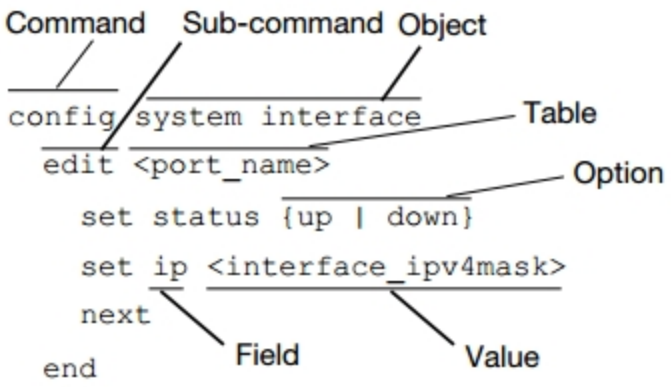
Terminology

Each command line consists of a command word that is usually followed by words for the configuration data or other specific item that the command uses or affects:

```
get system admin
```

To describe the function of each word in the command line, especially if that nature has changed between firmware versions, Fortinet uses terms with the following definitions.

Command syntax terminology



- **command** — A word that begins the command line and indicates an action that the FortiGate unit should perform on a part of the configuration or host on the network, such as `config` or `execute`. Together with other words, such as fields or values, that end when you press the Enter key, it forms a command line. Exceptions include multiline command lines, which can be entered using an escape sequence.
  Valid command lines must be unambiguous if abbreviated. Optional words or other command line permutations are indicated by syntax notation.
- **sub-command** — A kind of command that is available only when nested within the scope of another command. After entering a command, its applicable sub-commands are available to you until you exit the scope of the command, or until you descend an additional level into another sub-command. Indentation is used to indicate levels of nested commands.
  Not all top-level commands have sub-commands. Available sub-commands vary by their containing scope.
- **object** — A part of the configuration that contains tables and / or fields. Valid command lines must be specific enough to indicate an individual object.
- **table** — A set of fields that is one of possibly multiple similar sets which each have a name or number, such as an administrator account, policy, or network interface. These named or numbered sets are sometimes referenced by other parts of the configuration that use them.
- **field** — The name of a setting, such as `ip` or `hostname`. Fields in some tables must be configured with values. Failure to configure a required field will result in an invalid object configuration error message, and the FortiGate unit will discard the invalid table.
- **value** — A number, letter, IP address, or other type of input that is usually your configuration setting held by a field. Some commands, however, require multiple input values which may not be named but are simply entered in sequential order in the same command line. Valid input types are indicated by constraint notation.
- **option** — A kind of value that must be one or more words from of a fixed set of options.

Indentation

Indentation indicates levels of nested commands, which indicate what other sub-commands are available from within the scope. For example, the `edit` sub-command is available only within a command that affects tables, and the `next` sub-command is available only from within the `edit` sub-command:

```
config system interface
   edit port1
      set status up
      end
```

Notation

Brackets, braces, and pipes are used to denote valid permutations of the syntax. Constraint notations, such as `<address_ipv4>`, indicate which data types or string patterns are acceptable value input.

Command syntax notation

Convention	Description
Square brackets `[ ]`	A non-required word or series of words. For example: `[verbose {1 | 2 | 3}]` indicates that you may either omit or type both the `verbose` word and its accompanying option, such as `verbose 3`.
Angle brackets `< >`	A word constrained by data type. The angled brackets contain a descriptive name followed by an underscore (_) and suffix that indicates the valid data type. For example, `<retries_int>`, indicates that you should enter a number of retries, such as `5`. Data types include: • `<xxx_name>`: A name referring to another part of the configuration, such as `policy_A`. • `<xxx_index>`: An index number referring to another part of the configuration, such as `0` for the first static route. • `<xxx_pattern>`: A regular expression or word with wild cards that matches possible variations, such as `*@example.com` to match all email addresses ending in `@example.com`. • `<xxx_fqdn>`: A fully qualified domain name (FQDN), such as `mail.example.com`. • `<xxx_email>`: An email address, such as `admin@example.com`. • `<xxx_ipv4>`: An IPv4 address, such as `192.168.1.99`. • `<xxx_v4mask>`: A dotted decimal IPv4 netmask, such as `255.255.255.0`. • `<xxx_ipv4mask>`: A dotted decimal IPv4 address and netmask separated by a space, such as `192.168.1.99 255.255.255.0`. • `<xxx_ipv4/mask>`: A dotted decimal IPv4 address and CIDR-notation netmask separated by a slash, such as `192.168.1.1/24` • `<xxx_ipv4range>` : A hyphen (-)-delimited inclusive range of IPv4 addresses, such as `192.168.1.1-192.168.1.255`. • `<xxx_ipv6>`: A colon(:)-delimited hexadecimal IPv6 address, such as `3f2e:6a8b:78a3:0d82:1725:6a2f:0370:6234`. • `<xxx_v6mask>`: An IPv6 netmask, such as `/96`.

Convention	Description
	• <xxx_ipv6mask>: A dotted decimal IPv6 address and netmask separated by a space. • <xxx_str>: A string of characters that is not another data type, such as P@ssw0rd. Strings containing spaces or special characters must be surrounded in quotes or use escape sequences. • <xxx_int>: An integer number that is **not** another data type, such as 15 for the number of minutes.
Curly braces { }	A word or series of words that is constrained to a set of options delimited by either vertical bars or spaces. You must enter at least one of the options, unless the set of options is surrounded by square brackets [ ].
Options delimited by vertical bars |	Mutually exclusive options. For example: {enable | disable} indicates that you must enter either enable or disable, but must not enter both.
Options delimited by spaces	Non-mutually exclusive options. For example: {http https ping snmp ssh telnet} indicates that you may enter all or a subset of those options, in any order, in a space-delimited list, such as: ping https ssh

Sub-commands

Each command line consists of a command word that is usually followed by words for the configuration data or other specific item that the command uses or affects:

```
get system admin
```

Sub-commands are available from within the scope of some commands. When you enter a sub-command level, the command prompt changes to indicate the name of the current command scope. For example, after entering:

```
config system admin
```

the command prompt becomes:

```
(admin)#
```

Applicable sub-commands are available to you until you exit the scope of the command, or until you descend an additional level into another sub-command.

For example, the edit sub-command is available only within a command that affects tables; the next sub-command is available only from within the edit sub-command:

```
config system interface
```

```
edit port1
   set status up
   next
end
```

Sub-command scope is indicated by indentation.

Available sub-commands vary by command. From a command prompt within `config`, two types of sub-commands might become available:

- commands affecting fields
- commands affecting tables

Commands for tables

clone <table>	Clone (or make a copy of) a table from the current object.
	
	For example, in `config firewall policy`, you could enter the following command to clone security policy 27 to create security policy 30:
	
	`clone 27 to 30`
	
	In `config antivirus profile`, you could enter the following command to clone an antivirus profile named `av_pro_1` to create a new antivirus profile named `av_pro_2`:
	
	`clone av_pro_1 to av_pro_2`
	
	`clone` may not be available for all tables.

delete <table>	Remove a table from the current object. For example, in `config system admin`, you could delete an administrator account named `newadmin` by typing `delete newadmin` and pressing Enter. This deletes `newadmin` and all its fields, such as `newadmin`'s `first-name` and `email-address`. `delete` is only available within objects containing tables.

edit <table>	Create or edit a table in the current object. For example, in `config system admin`: • edit the settings for the default `admin` administrator account by typing `edit admin`. • add a new administrator account with the name `newadmin` and edit `newadmin`'s settings by typing `edit newadmin`. `edit` is an interactive sub-command: further sub-commands are available from within `edit`. `edit` changes the prompt to reflect the table you are currently editing. `edit` is only available within objects containing tables. In objects such as security policies, `<table>` is a sequence number. To create a new entry without the risk of overwriting an existing one, enter `edit 0`. The CLI initially confirms the creation of entry 0, but assigns the next unused number after you finish editing and enter `end`.
end	Save the changes to the current object and exit the `config` command. This returns you to the top-level command prompt.
get	List the configuration of the current object or table. • In objects, `get` lists the table names (if present), or fields and their values. • In a table, `get` lists the fields and their values. For more information on `get` commands, see the CLI Reference.
purge	Remove all tables in the current object. For example, in `config user local`, you could type `get` to see the list of user names, then type `purge` and then `y` to confirm that you want to delete all users. `purge` is only available for objects containing tables. **Caution:** Back up the FortiGate unit before performing a `purge`. `purge` cannot be undone. To restore purged tables, the configuration must be restored from a backup. **Caution:** Do not purge `system interface` or `system admin` tables. `purge` does not provide default tables. This can result in being unable to connect or log in, requiring the FortiGate unit to be formatted and restored.

rename <table> to <table>	Rename a table. For example, in `config system admin`, you could rename `admin3` to `fwadmin` by typing `rename admin3 to fwadmin`. `rename` is only available within objects containing tables.
show	Display changes to the default configuration. Changes are listed in the form of configuration commands.

Example of table commands

From within the `system admin` object, you might enter:

```
edit admin_1
```

The CLI acknowledges the new table, and changes the command prompt to show that you are now within the `admin_1` table:

```
new entry 'admin_1' added
(admin_1)#
```

Commands for fields

abort	Exit both the `edit` and/or `config` commands without saving the fields.
append	Add an option to an existing list.
end	Save the changes made to the current table or object fields, and exit the `config` command. (To exit without saving, use `abort` instead.)
get	List the configuration of the current object or table. • In objects, `get` lists the table names (if present), or fields and their values. • In a table, `get` lists the fields and their values.
move	Move an object within a list, when list order is important. For example, rearranging security policies within the policy list.
next	Save the changes you have made in the current table's fields, and exit the `edit` command to the object prompt. (To save and exit completely to the root prompt, use `end` instead.) `next` is useful when you want to create or edit several tables in the same object, without leaving and re-entering the `config` command each time. `next` is only available from a table prompt; it is not available from an object prompt.

select	Clear all options except for those specified. For example, if a group contains members A, B, C, and D and you remove all users except for B, use the command `select member B`.
set <field> <value>	Set a field's value. For example, in `config system admin`, after typing `edit admin`, you could type `set password newpass` to change the password of the `admin` administrator to `newpass`. **Note:** When using `set` to change a field containing a space-delimited list, type the whole new list. For example, `set <field> <new-value>` will replace the list with the `<new-value>` rather than appending `<new-value>` to the list.
show	Display changes to the default configuration. Changes are listed in the form of configuration commands.
unselect	Remove an option from an existing list.
unset <field>	Reset the table or object's fields to default values. For example, in `config system admin`, after typing `edit admin`, typing `unset password` resets the password of the `admin` administrator account to the default (in this case, no password).

Example of field commands

From within the `admin_1` table, you might enter:

```
set password my1stExamplePassword
```

to assign the value `my1stExamplePassword` to the `password` field. You might then enter the `next` command to save the changes and edit the next administrator's table.

Permissions

Access profiles control which CLI commands an administrator account can access. Access profiles assign either read, write, or no access to each area of the FortiGate software. To view configurations, you must have read access. To make changes, you must have write access. So, depending on the account used to log in to the FortiGate unit, you may not have complete access to all CLI commands

Unlike other administrator accounts, the `admin` administrator account exists by default and cannot be deleted. The `admin` administrator account is similar to a root administrator account. This administrator account always has full permission to view and change all FortiGate configuration options, including viewing and changing **all** other administrator accounts. Its name and permissions cannot be changed. It is the only administrator account that can reset another administrator's password without being required to enter that administrator's existing password.

Set a strong password for the `admin`administrator account, and change the password regularly. By default, this administrator account has no password. Failure to maintain the password of the `admin` administrator account could compromise the security of your FortiGate unit.

For complete access to all commands, you must log in with the administrator account named `admin`.

Tips

Basic features and characteristics of the CLI environment provide support and ease of use for many CLI tasks.

Help

To display brief help during command entry, press the question mark (?) key.

- Press the question mark (?) key at the command prompt to display a list of the commands available and a description of each command.
- Type a word or part of a word, then press the question mark (?) key to display a list of valid word completions or subsequent words, and to display a description of each.

Shortcuts and key commands

Shortcuts and key commands

Action	Keys
List valid word completions or subsequent words. If multiple words could complete your entry, display all possible completions with helpful descriptions of each.	?
Complete the word with the next available match. Press the key multiple times to cycle through available matches.	Tab
Recall the previous command. Command memory is limited to the current session.	Up arrow, or Ctrl + P
Recall the next command.	Down arrow, or Ctrl + N
Move the cursor left or right within the command line.	Left or Right arrow
Move the cursor to the beginning of the command line.	Ctrl + A
Move the cursor to the end of the command line.	Ctrl + E
Move the cursor backwards one word.	Ctrl + B

Action	Keys
Move the cursor forwards one word.	Ctrl + F
Delete the current character.	Ctrl + D
Abort current interactive commands, such as when entering multiple lines. If you are not currently within an interactive command such as `config` or `edit`, this closes the CLI connection.	Ctrl + C
Continue typing a command on the next line for a multi-line command. For each line that you want to continue, terminate it with a backslash (\ ). To complete the command line, terminate it by pressing the spacebar and then the Enter key, without an immediately preceding backslash.	\ then Enter

Command abbreviation

You can abbreviate words in the command line to their smallest number of non-ambiguous characters.

For example, the command `get system status` could be abbreviated to `g sy stat`.

Adding and removing options from lists

When adding options to a list, such as a user group, using the `set` command will remove the previous configuration. For example. if you wish to add user D to a user group that already contains members A, B, and C, the command would need to be `set member A B C D`. If only `set member D` was used, then all former members would be removed from the group.

However, there are additional commands which can be used instead of `set` for changing options in a list.

Additional commands for lists

append	Add an option to an existing list. For example, `append member` would add user D to a user group while all previous group members are retained
select	Clear all options except for those specified. For example, if a group contains members A, B, C, and D and you remove all users except for B, use the command `select member B`.
unselect	Remove an option from an existing list. For example, `unselect member A` would remove member A from a group will all previous group members are retained.

Environment variables

The CLI supports the following environment variables. Variable names are case-sensitive.

Environment variables

$USERFROM	The management access type (`ssh`, `telnet`, `jsconsole` for the **CLI Console** widget in the web-based manager, and so on) and the IP address of the administrator that configured the item.
$USERNAME	The account name of the administrator that configured the item.
$SerialNum	The serial number of the FortiGate unit.

For example, the FortiGate unit's host name can be set to its serial number.

```
config system global
   set hostname $SerialNum
end
```

Special characters

The characters <, >, (,), #, ', and " are not permitted in most CLI fields. These characters are special characters, also known as reserved characters.

You may be able to enter special character as part of a string's value by using a special command, enclosing it in quotes, or preceding it with an escape sequence — in this case, a backslash (\ ) character.

In other cases, different keystrokes are required to input a special character. If you need to enter ? as part of config, you first need to input CTRL-V. If you enter the question mark (?) without first using CTRL-V, the question mark has a different meaning in CLI: it will show available command options in that section.

For example, if you enter ? without CTRL-V:

```
edit "*.xe
token line: Unmatched double quote.
```

If you enter ? with CTRL-V:

```
edit "*.xe?"
new entry '*.xe?' added
```

Entering special characters

Character	Keys
?	Ctrl + V then ?
Tab	Ctrl + V then Tab
Space (to be interpreted as part of a string value, not to end the string)	Enclose the string in quotation marks: `"Security Administrator"`. Enclose the string in single quotes: `'Security Administrator'`. Precede the space with a backslash: `Security\ Administrator`.

Character	Keys
' (to be interpreted as part of a string value, not to end the string)	\'
" (to be interpreted as part of a string value, not to end the string)	\"
\	\\

Using grep to filter get and show command output

In many cases, the `get` and `show` (and `diagnose`) commands may produce a large amount of output. If you are looking for specific information in a large get or show command output, you can use the grep command to filter the output to only display what you are looking for. The `grep` command is based on the standard UNIX grep, used for searching text output based on regular expressions.

Use the following command to display the MAC address of the FortiGate unit internal interface:

```
get hardware nic internal | grep Current_HWaddr
Current_HWaddr             00:09:0f:cb:c2:75
```

Use the following command to display all TCP sessions in the session list and include the session list line number in the output

```
get system session list | grep -n tcp
```

Use the following command to display all lines in HTTP replacement message commands that contain `URL` (upper or lower case):

```
show system replacemsg http | grep -i url
```

There are three additional options that can be applied to grep:

```
-A <num> After
-B <num> Before
-C <num> Context
```

The option `-f` is also available to support Fortinet contextual output, in order to show the complete configuration. The following example shows the difference in output when `-f` option is used versus when it is not.

Using -f:

```
show | grep -f ldap-group1
   config user group
      edit "ldap-group1"
         set member "pc40-LDAP"
      next
   end
   config firewall policy
      edit 2
         set srcintf "port31"
```

```
            set dstintf "port32"
            set srcaddr "all"
            set action accept
            set identity-based enable
            set nat enable
            config identity-based-policy
               edit 1
                  set schedule "always"
                  set groups "ldap-group1"
                  set dstaddr "all"
                  set service "ALL"
               next
            end
         next
      end
```

Without using -f:

```
show | grep ldap-group1
   edit "ldap-group1"
      set groups "ldap-group1"
```

Language support and regular expressions

Characters such as ñ, é, symbols, and ideographs are sometimes acceptable input. Support varies by the nature of the item being configured. CLI commands, objects, field names, and options must use their exact ASCII characters, but some items with arbitrary names or values may be input using your language of choice. To use other languages in those cases, you must use the correct encoding.

Input is stored using Unicode UTF-8 encoding but is not normalized from other encodings into UTF-8 before it is stored. If your input method encodes some characters differently than in UTF-8, your configured items may not display or operate as expected.

Regular expressions are especially impacted. Matching uses the UTF-8 character values. If you enter a regular expression using another encoding, or if an HTTP client sends a request in an encoding other than UTF-8, matches may not be what you expect.

For example, with Shift-JIS, backslashes (\ ) could be inadvertently interpreted as the symbol for the Japanese yen (¥) and vice versa. A regular expression intended to match HTTP requests containing money values with a yen symbol therefore may not work it if the symbol is entered using the wrong encoding.

For best results, you should:

- use UTF-8 encoding, or
- use only the characters whose numerically encoded values are the same in UTF-8, such as the US-ASCII characters that are also encoded using the same values in ISO 8859-1, Windows code page 1252, Shift-JIS and other encodings, or
- for regular expressions that must match HTTP requests, use the same encoding as your HTTP clients.

HTTP clients may send requests in encodings other than UTF-8. Encodings usually vary by the client's operating system or input language. If you cannot predict the client's encoding, you may only be able to match any parts of the request that are in English, because regardless of the encoding, the values for English characters tend to be encoded identically. For example, English words may be legible regardless of interpreting a web page as either ISO 8859-1 or as GB2312, whereas simplified Chinese characters might only be legible if the page is interpreted as GB2312.

If you configure your FortiGate unit using other encodings, you may need to switch language settings on your management computer, including for your web browser or Telnet/SSH client. For instructions on how to configure your management computer's operating system language, locale, or input method, see its documentation.

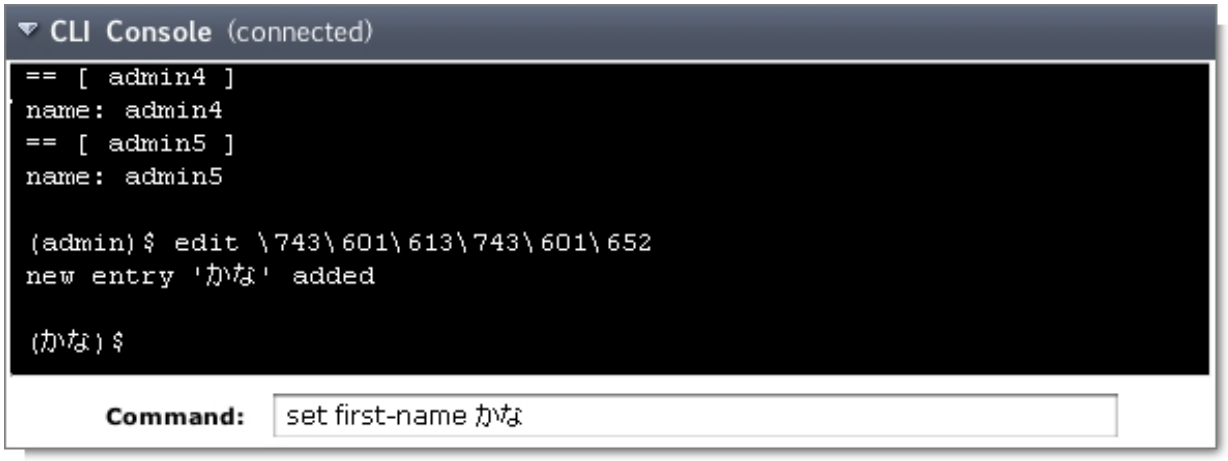
If you choose to configure parts of the FortiGate unit using non-ASCII characters, verify that all systems interacting with the FortiGate unit also support the same encodings. You should also use the same encoding throughout the configuration if possible in order to avoid needing to switch the language settings of the web-based manager and your web browser or Telnet/SSH client while you work.

Similarly to input, your web browser or CLI client should usually interpret display output as encoded using UTF-8. If it does not, your configured items may not display correctly in the web-based manager or CLI. Exceptions include items such as regular expressions that you may have configured using other encodings in order to match the encoding of HTTP requests that the FortiGate unit receives.

To enter non-ASCII characters in the CLI Console widget

1. On your management computer, start your web browser and go to the URL for the FortiGate unit's web-based manager.
2. Configure your web browser to interpret the page as UTF-8 encoded.
3. Log in to the FortiGate unit.
4. Go to **System > Dashboard > Status**.
5. In title bar of the **CLI Console** widget, click **Edit** (the pencil icon).
6. Enable **Use external command input box**.
7. Select **OK**.
8. The **Command** field appears below the usual input and display area of the **CLI Console** widget.
9. In **Command**, type a command.

Entering encoded characters (CLI Console widget):



10. Press **Enter**.

    In the display area, the ***CLI Console*** widget displays your previous command interpreted into its character code equivalent, such as:

    ```
    edit \743\601\613\743\601\652
    ```

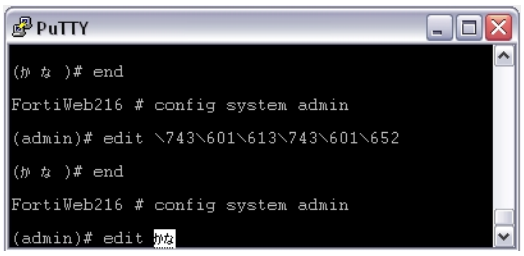
    and the command's output.

To enter non-ASCII characters in a Telnet/SSH client

1. On your management computer, start your Telnet or SSH client.
2. Configure your Telnet or SSH client to send and receive characters using UTF-8 encoding.

   Support for sending and receiving international characters varies by each Telnet/SSH client. Consult the documentation for your Telnet/SSH client.
3. Log in to the FortiGate unit.
4. At the command prompt, type your command and press Enter.

Entering encoded characters (PuTTY):



You may need to surround words that use encoded characters with single quotes (').

Depending on your Telnet/SSH client's support for your language's input methods and for sending international characters, you may need to interpret them into character codes before pressing Enter.

For example, you might need to enter:

```
edit '\743\601\613\743\601\652'
```

5. The CLI displays your previous command and its output.

Screen paging

You can configure the CLI to pause after displaying each page's worth of text when displaying multiple pages of output. When the display pauses, the last line displays `--More--`. You can then either:

- press the spacebar to display the next page.
- type `Q` to truncate the output and return to the command prompt.

This may be useful when displaying lengthy output, such as the list of possible matching commands for command completion, or a long list of settings. Rather than scrolling through or possibly exceeding the buffer of your terminal emulator, you can simply display one page at a time.

To configure the CLI display to pause when the screen is full:

```
config system console
   set output more
end
```

Baud rate

You can change the default baud rate of the local console connection.

To change the baud rate enter the following commands:

```
config system console
   set baudrate {115200 | 19200 | 38400 | 57600 | 9600}
end
```

Editing the configuration file on an external host

You can edit the FortiGate configuration on an external host by first backing up the configuration file to a TFTP server. Then edit the configuration file and restore it to the FortiGate unit.

Editing the configuration on an external host can be timesaving if you have many changes to make, especially if your plain text editor provides advanced features such as batch changes.

To edit the configuration on your computer

1. Use `execute backup` to download the configuration file to a TFTP server, such as your management computer.
2. Edit the configuration file using a plain text editor that supports Unix-style line endings.

Do not edit the first line. The first line(s) of the configuration file (preceded by a `#` character) contains information about the firmware version and FortiGate model. If you change the model number, the FortiGate unit will reject the configuration file when you attempt to restore it.

3. Use `execute restore` to upload the modified configuration file back to the FortiGate unit.

   The FortiGate unit downloads the configuration file and checks that the model information is correct. If it is, the FortiGate unit loads the configuration file and checks each command for errors. If a command is invalid, the FortiGate unit ignores the command. If the configuration file is valid, the FortiGate unit restarts and loads the new configuration.

FortiGate LED Specifications

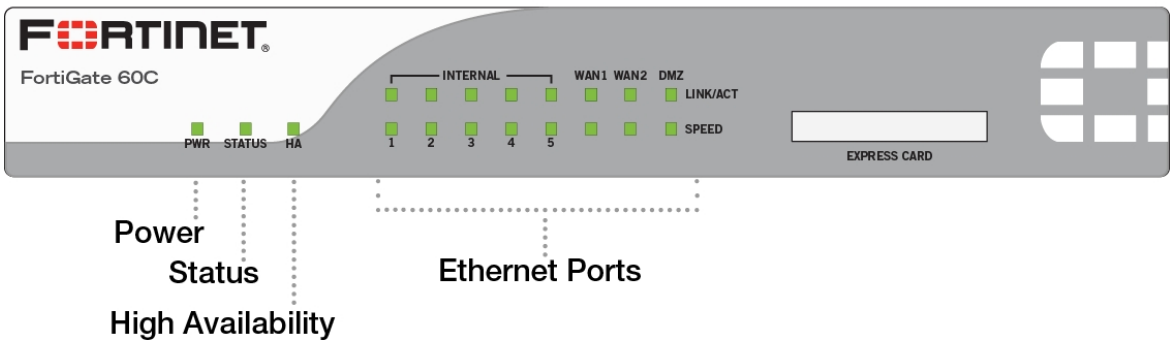
This is a guide to FortiGate LED status indicators.

- Sample FortiGate Faceplates
- LED Status Codes
- About Alarm Levels
- LED Status Codes for Ports

Sample FortiGate Faceplates

The faceplates indicate where the LEDs are typically found on desktop and mid-range FortiGate models.

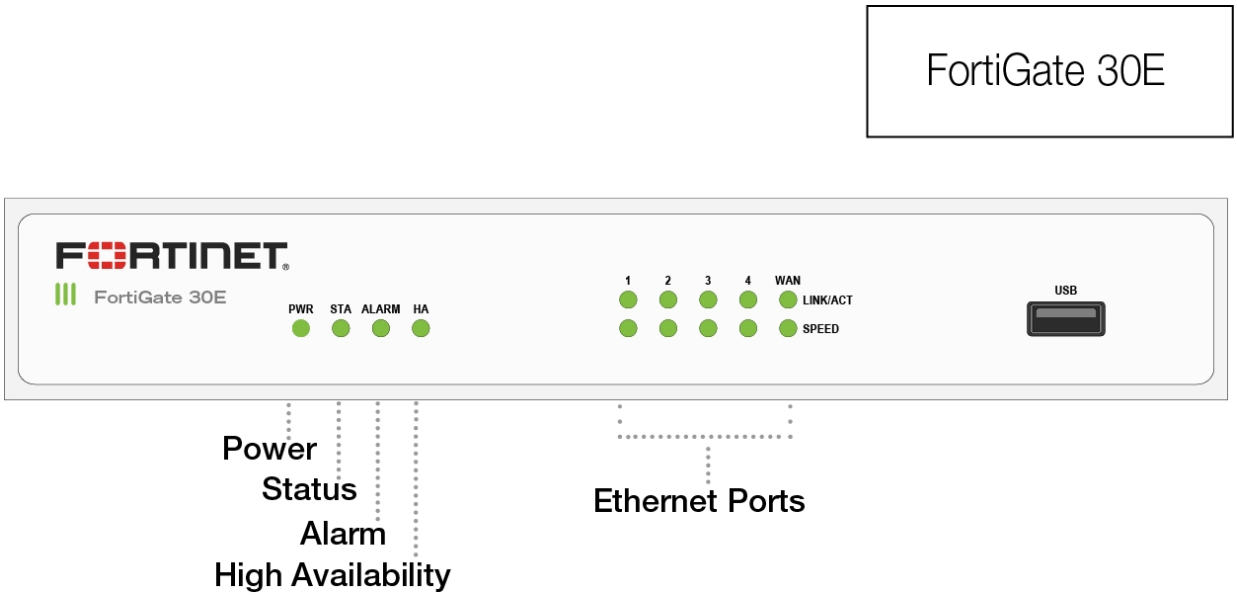
FortiGate 60C



Power
Status
High Availability
Ethernet Ports

FortiGate 100D

Alarm
Status
Power
High Availability
Ethernet Ports
SFP Ports



LED Status Codes

LABEL	STATE	MEANING
PWR	Green	Power is On.
	Off	Power is Off.
STA	Green	Normal status.
	Flashing Green	Booting Up. If the FortiGate has a reset button, Flashing Green also means that the reset button was used.
	Red	The FortiGate has a critical alarm (see About Alarm Levels).
ALARM	Off	No alarms or the FortiGate has a minor alarm.
	Amber	The FortiGate has a major alarm.
	Red	The FortiGate has a critical alarm. The status LED will also be red.
		More information at About Alarm Levels.
HA	Green	FortiGate is operating in an FGCP HA cluster.
	Red	A failover has occurred.
	Off	HA not configured.
		Failover operation feature not available in all units.

LABEL	STATE	MEANING
WIFI	Green	Wireless port is active.
	Flashing Green	Wireless interface is transmitting and receiving data.
	Off	Wireless interface is down.

About Alarm Levels

Minor, major, and critical alarms are defined based on IPMI, ATCA, and Telco standards for naming alarms.

- A minor alarm (also called an IPMI non-critical (NC) alarm) indicates a temperature or a power level outside of the normal operating range that is not considered a problem. In the case of a minor temperature alarm, the system could respond by increasing fan speed. A non-critical threshold can be an upper non-critical (UNC) threshold (for example, a high temperature or a high power level) or a lower non-critical (UNC) threshold (for example, a low power level). The LEDs do not indicate minor alarms since user intervention is not required.
- A major alarm (also called an IPMI critical or critical recoverable(CR) alarm) indicates that the system itself cannot correct the cause for the alarm and that intervention is required. For example, the cooling system cannot provide enough cooling to reduce the temperature. It could also mean that conditions (temperature, for example) are approaching the outside limit of the allowed operating range. A critical threshold can also be an upper critical (UC) threshold (for example, a high temperature or a high power level) or a lower critical (LC) threshold (for example, a low power level).
- A critical alarm (also called and IPMI non-recoverable (NR) alarm) indicates detection of a temperature or power level that is outside of the allowed operating range and could potentially cause physical damage.

LED Status Codes for Ports

TYPE OF PORT	STATE	MEANING
Ethernet Ports Link / Activity	Green	Connected.
	Flashing Green	Transmitting and receiving data.
	Off	No link established.
		On FortiGate models with front-facing ports, this LED is to the left of the port. On FortiGate models with ports at the back of the device, this LED is in the upper row.
Ethernet Ports Speed	Green	Connected at 1Gbps.
	Amber	Connected at 100Mbps.
	Off	Not connected or connected at 10Mbps.
		On FortiGate models with front-facing ports, this LED is to the right of the port. On FortiGate models with ports at the back of the device, this LED is in the lower row.

TYPE OF PORT	STATE	MEANING
SFP Ports	Green	Connected.
	Flashing Green	Transmitting and receiving data.
	Off	No link established.

FortiGate Inspection Mode

You can select Flow or Proxy Inspection Mode from the System Information dashboard widget to control your FortiGate's security profile inspection mode. Having control over flow and proxy mode is helpful if you want to be sure that only flow inspection mode is used (and that proxy inspection mode is not used).

Switching to Flow Inspection Mode also turns off WAN Optimization, Web Caching, the Explicit Web Proxy, and the Explicit FTP Proxy making sure that no proxying can occur.

In most cases proxy mode is preferred because more security profile features are available and more configuration options for these individual features are available. Some implementations; however, may require all security profile scanning to only use flow mode. In this case, you can set your FortiGate to flow mode knowing that proxy mode inspection will not be used.

If you select flow-based to use external servers for FortiWeb and FortiMail you must use the CLI to set a Web Application Firewall profile or Anti-Spam profile to external mode and add the Web Application Firewall profile or Anti-Spam profile to a firewall policy.

Changing between proxy and flow mode

Proxy mode is enabled by default and you change to flow mode by changing the **Inspection Mode** on the System Information dashboard widget.

When you select **Flow-based** you are reminded that all proxy mode profiles are converted to flow mode, removing any proxy settings. As well proxy-mode only features (for example, Web Application Profile) are removed from the GUI.

In addition, selecting **Flow-based** inspection will cause the **Explicit Web Proxy** and **Explicit FTP Proxy** features to be removed from the GUI and the CLI. This includes Explicit Proxy firewall policies.

When you select **Flow-based** you can only configure Virtual Servers (under **Policy & Objects > Virtual Servers**) with Type set to HTTP, TCP, UDP, or IP.

If required, you can change back to proxy mode through the System Information dashboard widget.

If your FortiGate has multiple VDOMs, you can set the inspection mode independently for each VDOM. Use the top left dropdown menu to go to **Global > System > VDOM**. Click **Edit** for the VDOM you wish to change and select the **Inspection Mode**.

Security profile features mapped to inspection mode

The table below lists FortiOS security profile features and shows whether they are available in flow-based or proxy-based inspection modes.

The DNS Filter security profile feature is only available for proxy-based inspection in FortiOS versions 5.4.0 and 5.4.1. It is available for both proxy-based and flow-based inspection in FortiOS versions 5.4.2 and above.

Security Profile Feature	Flow-based inspection	Proxy-based inspection
AntiVirus	x	x
Web Filter	x	x
DNS Filter	x	x
Application Control	x	x
Cloud Access Security Inspection	x	x
Intrusion Protection	x	x
Anti-Spam		x
Data Leak Protection		x
VoIP		x
ICAP		x
Web Application Firewall		x
FortiClient Profiles	x	x
Proxy Options		x
SSL/SSH Inspection	x	x
Web Rating Overrides	x	x
Web Profile Overrides		x

From the GUI, you can only configure antivirus and web filter security profiles in proxy mode. From the CLI you can configure flow-based antivirus profiles, web filter profiles and DLP profiles and they will appear on the GUI and include their inspection mode setting. Also, flow-based profiles created when in flow mode are still available when you switch to proxy mode.

In flow mode, antivirus and web filter profiles only include flow-mode features. Web filtering and virus scanning is still done with the same engines and to the same accuracy, but some inspection options are limited or not available in flow mode. Application control, intrusion protection, and FortiClient profiles are not affected when switching between flow and proxy mode.

CASI does not work when using proxy-based profiles for AV or Web filtering. Make sure to only use flow-based profiles in combination with CASI on a specific policy.

Even though VoIP profiles are not available from the GUI in flow mode, the FortiGate can process VoIP traffic. In this case the appropriate session helper is used (for example, the SIP session helper).

Setting flow or proxy mode doesn't change the settings available from the CLI. However, when in flow mode you can't save security profiles that are set to proxy mode.

You can also add proxy-only security profiles to firewall policies from the CLI. So, for example, you can add a VoIP profile to a security policy that accepts VoIP traffic. This practice isn't recommended because the setting will not be visible from the GUI.

Proxy mode and flow mode antivirus and web filter profile options

The following tables list the antivirus and web filter profile options available in proxy and flow modes.

Antivirus features in proxy and flow mode

Feature	Proxy	Flow
Scan Mode (Quick or Full)	no	yes
Detect viruses (Block or Monitor)	yes	yes
Inspected protocols	yes	no (all relevant protocols are inspected)
Inspection Options	yes	yes (not available for quick scan mode)
Treat Windows Executables in Email Attachments as Viruses	yes	yes
Send Files to FortiSandbox Appliance for Inspection	yes	yes
Use FortiSandbox Database	yes	yes
Include Mobile Malware Protection	yes	yes

Web Filter features in proxy and flow mode

Feature		Proxy	Flow
FortiGuard category based filter		yes	yes (show, allow, monitor, block)
Category Usage Quota		yes	no
Allow users to override blocked categories (on some models)		yes	no
Search Engines		yes	no
	Enforce 'Safe Search' on Google, Yahoo!, Bing, Yandex	yes	no
	Restrict YouTube Access	yes	no
	Log all search keywords	yes	no
Static URL Filter		yes	yes
	Block invalid URLs	yes	no
	URL Filter	yes	yes
	Block malicious URLs discovered by FortiSandbox	yes	yes
	Web Content Filter	yes	yes
Rating Options		yes	yes
	Allow websites when a rating error occurs	yes	yes
	Rate URLs by domain and IP Address	yes	yes
	Block HTTP redirects by rating	yes	no
	Rate images by URL	yes	no
Proxy Options		yes	no

Feature		Proxy	Flow
	Restrict Google account usage to specific domains	yes	no
	Provide details for blocked HTTP 4xx and 5xx errors	yes	no
	HTTP POST Action	yes	no
	Remove Java Applets	yes	no
	Remove ActiveX	yes	no
	Remove Cookies	yes	no
	Filter Per-User Black/White List	yes	no

A Guide to Using the Entry Level Models

Disabling the GUI lite on 30D models

Basic Administration

This section contains information about basic FortiGate administration that can be done after you have installed the unit in your network.

While this section mainly focuses on accomplishing tasks with the GUI, some tasks include instructions to use the command line interface (CLI). You can connect to the CLI using the CLI widget on the Dashboard, or through FortiExplorer, or by connecting using a SSH or Telnet connection. For more information about the CLI, see Using the CLI.

The following topics are included in this section:

- Registration
- System Settings
- Administrators
- Passwords
- Firmware
- Configuration Backups
- FortiGuard
- FortiCloud

Registration

In order to have full access to Fortinet Support and FortiGuard Services, you must register your FortiGate.

Registering your FortiGate:

1. Go to the **Dashboard** and locate the **License Information** widget.
2. Select **Register**.
3. In the pop-up window, either use an existing Fortinet Support account or create a new one. Select your **Country** and **Reseller**.
4. Select **OK**.

FortiGate platforms do not impose any limitations on the number or type of customers, users, devices, IP addresses, or number of VPN clients being served by the platform. Such factors are limited solely by the hardware capacity of each given model.

Passwords

Using secure passwords are vital for preventing unauthorized access to your FortiGate. When changing the password, consider the following to ensure better security:

- Do not make passwords that are obvious, such as the company name, administrator names, or other obvious word or phrase.
- Use numbers in place of letters, for example, `passw0rd`. Alternatively, spell words with extra letters, for example, **password**.
- Administrator passwords can be up to 64 characters.
- Include a mixture of letters, numbers, and upper and lower case.
- Use multiple words together, or possibly even a sentence, for example keytothehighway.
- Use a password generator.
- Change the password regularly and always make the new password unique and not a variation of the existing password, such as changing from `password` to `password1`.
- Write the password down and store it in a safe place away from the management computer, in case you forget it or ensure that at least two people know the password in the event that one person becomes ill, is away on vacation or leaves the company. Alternatively, have two different admin logins.

Password policy

The FortiGate includes the ability to create a password policy for administrators. With this policy, you can enforce regular changes and specific criteria for a password including:

- minimum length between 8 and 64 characters.
- if the password must contain uppercase (A, B, C) and/or lowercase (a, b, c) characters.
- if the password must contain numbers (1, 2, 3).
- if the password must contain non-alphanumeric characters (!, @, #, $, %, ^, &, *, ().
- where the password applies (admin or IPsec or both).
- the duration of the password before a new one must be specified.

To create a password policy - GUI

1. Go to **System > Settings**.
2. Select **Enable Password Policy** and configure the settings as required.

If you add a password policy or change the requirements on an existing policy, the next time that administrator logs into the FortiGate, they are prompted to update their password to meet the new requirements before proceeding to log in.

For information about recovering a lost password and enhancements to the process, see: Resetting a lost Admin password on the Fortinet Cookbook site.

Lost Passwords

If an administrator password has been lost, refer to the SysAdmin Note on the Fortinet Cookbook site: Resetting a lost admin password.

Firmware

Fortinet periodically updates the FortiGate firmware to include new features and resolve important issues. After you have registered your FortiGate unit, you can download firmware updates from the support web site, https://support.fortinet.com.

Before you install any new firmware, be sure to follow the steps below:

- Review the Release Notes for a new firmware release.
- Review the Supported Upgrade Paths document to make sure the upgrade from your current image to the desired new image is supported.
- Backup the current configuration, including local certificates.
- Test the new firmware until you are satisfied that it applies to your configuration.

Installing new firmware without reviewing release notes or testing the firmware may result in changes to settings or unexpected issues.

Only FortiGate admin users and administrators whose access profiles contain system read and write privileges can change the FortiGate firmware.

Backing up the current configuration

You should always back up the configuration before installing new firmware, in case you need to restore your FortiGate configuration.

To create a local backup:

1. Go to **Dashboard** and locate the **System Information** widget.
2. Select **Backup** beside **System Configuration**.
3. Choose either **Local PC** or **USB Disk** to save the configuration file. The USB option will not be available if there is no USB drive in the USB port.
4. If desired, select **Encrypt configuration file**.
5. Select **OK**.

For more information, see Configuration Backups.

Restoring configuration

Rather than reconfigure the FortiGate manually, it is possible to upload a saved configuration file.

To restore your FortiGate configuration

1. Go to **Dashboard** and locate the **System Information** widget.
2. Select **[Restore]** beside **System Configuration**.
3. Choose either **Local PC** or **USB Disk** depending the location of the file.
4. Select **Choose File** and browse to the correct file in the file manager window.
5. If a password was associated with the configuration file, enter it in the **Password** field.
6. Select **Restore**.

Troubleshooting

During the installation there are some possible errors that you may come across but the solutions are usually straightforward.

.

Error message	Reason and Solution
Configuration file error	This error occurs when attempting to upload a configuration file that is incompatible with the device. This may be due to the configuration file being for a different model or being saved from a different version of firmware. **Solution**: upload a configuration file that is for the correct model of FortiGate device and the correct version of the firmware.
Invalid password	When the configuration file is saved, it can be protected by a password. The password entered during the upload process is not matching the one associated with the configuration file. **Solution**: use the correct password if the file is password protected.

Downloading firmware

Firmware images for all FortiGate units are available on the Fortinet Customer Support website, https://support.fortinet.com.

To download firmware

1. Log into the site using your user name and password.
2. Go to **Download > Firmware Images**.
3. A list of Release Notes is shown. If you have not already done so, download and review the Release Notes for the firmware you wish to upgrade your FortiGate unit to.
4. Select **HTTPS Download**.

Firmware can also be downloaded using FTP; however, as FTP is not an encrypted file transferring protocol, HTTPS downloading is recommended.

5. Navigate to find the folder for the firmware version you wish to use.
6. Select your FortiGate model from the list. If your unit is a FortiWiFi, be sure to get the appropriate firmware, which will have a filename starting with FWF.
7. Save the firmware image to your computer.

Testing new firmware

The integrity of a firmware images downloaded from Fortinet's support portal can be verified using a file checksum. A file checksum that does not match the expected value indicates a corrupt file. The corruption could

be caused by errors in transfer or by file modification. A list of expected checksum values for each build of released code is available on Fortinet's support portal.

Image integrity is also verified when the FortiGate is booting up. This integrity check is done through cyclic redundancy check (CRC). If the CRC fails, the Fortinet unit will error during the boot process, preventing suboptimal operation of the device.

Lastly, firmware images are signed and the signature is attached to the code as it is built. When upgrading an image, the running OS will generate a signature and compare it with the signature attached to the image. If the signatures do not match, the new OS will not load.

Testing before installation

FortiOS enables you to test a new firmware image by installing the firmware image from a system reboot and saving it to system memory. After completing this procedure, the FortiGate unit operates using the new firmware image with the current configuration. This new firmware image is not permanently installed. The next time the FortiGate unit restarts, it operates with the originally installed firmware image using the current configuration. If the new firmware image operates successfully, you can install it permanently using the procedure Testing new firmware on page 295 or Upgrading the firmware - CLI.

To use this procedure, you must connect to the CLI using the FortiGate console port and an RJ-45 to DB-9 or null modem cable. This procedure temporarily installs a new firmware image using your current configuration.

For this procedure, you must install a TFTP server that you can connect to from the FortiGate internal interface. The TFTP server should be on the same subnet as the internal interface.

To test the new firmware image

1. Connect to the CLI using a RJ-45 to DB-9 or null modem cable.
2. Make sure the TFTP server is running.
3. Copy the new firmware image file to the root directory of the TFTP server.
4. Make sure the FortiGate unit can connect to the TFTP server using the `execute ping` command.
5. Enter the following command to restart the FortiGate unit:
   ```
   execute reboot
   ```
6. As the FortiGate unit reboots, press any key to interrupt the system startup. As the FortiGate unit starts, a series of system startup messages appears.
   When the following messages appears:
   ```
   Press any key to display configuration menu....
   ```
7. Immediately press any key to interrupt the system startup.

You have only 3 seconds to press any key. If you do not press a key soon enough, the FortiGate unit reboots and you must login and repeat the execute reboot command.

If you successfully interrupt the startup process, the following messages appears:

```
[G]: Get firmware image from TFTP server.
[F]: Format boot device.
[B]: Boot with backup firmware and set as default
[C]: Configuration and information
```

```
[Q]: Quit menu and continue to boot with default firmware.
    [H]: Display this list of options.
Enter G, F, Q, or H:
```

8. Type **G** to get the new firmware image from the TFTP server.

   The following message appears:

   ```
   Enter TFTP server address [192.168.1.168]:
   ```

9. Type the address of the TFTP server and press **Enter**.

   The following message appears:

   ```
   Enter Local Address [192.168.1.188]:
   ```

10. Type an IP address of the FortiGate unit to connect to the TFTP server.

    The IP address must be on the same network as the TFTP server.

Make sure you do not enter the IP address of another device on this network.

The following message appears:

```
Enter File Name [image.out]:
```

11. Enter the firmware image file name and press **Enter**.

    The TFTP server uploads the firmware image file to the FortiGate unit and the following appears.

    ```
    Save as Default firmware/Backup firmware/Run image without saving: [D/B/R]
    ```

12. Type `R`.

    The FortiGate image is installed to system memory and the FortiGate unit starts running the new firmware image, but with its current configuration.

You can test the new firmware image as required. When done testing, you can reboot the FortiGate unit, and the FortiGate unit will resume using the firmware that was running before you installed the test firmware.

Upgrading the firmware - GUI

Installing firmware replaces your current antivirus and attack definitions, along with the definitions included with the firmware release you are installing. After you install new firmware, make sure that antivirus and attack definitions are up to date.

Always remember to back up your configuration before making any changes to the firmware.

Be sure to read the topics on downloading and testing firmware before upgrading.

To upgrade the firmware

1. Log into the GUI as the admin administrative user.
2. Go to **Dashboard** and locate the **System Information** widget.
3. Beside **Firmware Version**, select **Update**.
4. Type the path and filename of the firmware image file, or select **Browse** and locate the file.
5. Select **OK**.

The FortiGate unit uploads the firmware image file, upgrades to the new firmware version, restarts, and displays the FortiGate login. This process takes a few minutes.

Reverting to a previous firmware version - GUI

The following procedures revert the FortiGate unit to its factory default configuration and deletes any configuration settings. If you are reverting to a previous FortiOS version, you might not be able to restore the previous configuration from the backup configuration file.

Always remember to back up your configuration before making any changes to the firmware.

To revert to a previous firmware version

1. Go to **Dashboard** and locate the **System Information**widget.
2. Beside **Firmware Version**, select **Update**.
3. Type the path and filename of the firmware image file, or select **Browse** and locate the file of the previous firmware version.
4. Select **OK**.

The FortiGate unit uploads the firmware image file, reverts to the old firmware version, resets the configuration, restarts, and displays the FortiGate login. This process takes a few minutes.

Upgrading the firmware - CLI

Installing firmware replaces your current antivirus and attack definitions, along with the definitions included with the firmware release you are installing. After you install new firmware, make sure that antivirus and attack definitions are up to date. You can also use the CLI command `execute update-now` to update the antivirus and attack definitions. For more information, see the System Administration handbook.

Before you begin, ensure you have a TFTP server running and accessible to the FortiGate unit.

Always remember to back up your configuration before making any changes to the firmware.

To upgrade the firmware using the CLI

1. Make sure the TFTP server is running.
2. Copy the new firmware image file to the root directory of the TFTP server.
3. Log into the CLI.
4. Make sure the FortiGate unit can connect to the TFTP server.

   You can use the following command to ping the computer running the TFTP server. For example, if the IP address of the TFTP server is 192.168.1.168:

   ```
   execute ping 192.168.1.168
   ```

5. Enter the following command to copy the firmware image from the TFTP server to the FortiGate unit:

   ```
   execute restore image tftp <filename> <tftp_ipv4>
   ```

   Where `<name_str>` is the name of the firmware image file and `<tftp_ipv4>` is the IP address of the TFTP server. For example, if the firmware image file name is `image.out` and the IP address of the TFTP server is 192.168.1.168, enter:

   ```
   execute restore image tftp image.out 192.168.1.168
   ```

   The FortiGate unit responds with the message:

   ```
   This operation will replace the current firmware version!
       Do you want to continue? (y/n)
   ```

6. Type `y`.
7. The FortiGate unit uploads the firmware image file, upgrades to the new firmware version, and restarts. This process takes a few minutes.
8. Reconnect to the CLI.
9. Update antivirus and attack definitions, by entering:

   ```
   execute update-now
   ```

Installing firmware from a system reboot - CLI

In the event that the firmware upgrade does not load properly and the FortiGate unit will not boot, or continuously reboots. If this occurs, it is best to perform a fresh install of the firmware from a reboot using the CLI.

This procedure installs a firmware image and resets the FortiGate unit to default settings. You can use this procedure to upgrade to a new firmware version, revert to an older firmware version, or re-install the current firmware.

To use this procedure, you must connect to the CLI using the FortiGate console port and a RJ-45 to DB-9, or null modem cable. This procedure reverts the FortiGate unit to its factory default configuration.

For this procedure you install a TFTP server that you can connect to from the FortiGate internal interface. The TFTP server should be on the same subnet as the internal interface.

Before beginning this procedure, ensure you back up the FortiGate unit configuration.

If you are reverting to a previous FortiOS version, you might not be able to restore the previous configuration from the backup configuration file.

Installing firmware replaces your current antivirus and attack definitions, along with the definitions included with the firmware release you are installing. After you install new firmware, make sure that antivirus and attack definitions are up to date.

To install firmware from a system reboot

1. Connect to the CLI using the RJ-45 to DB-9 or null modem cable.
2. Make sure the TFTP server is running.
3. Copy the new firmware image file to the root directory of the TFTP server.
4. Make sure the internal interface is connected to the same network as the TFTP server.
5. To confirm the FortiGate unit can connect to the TFTP server, use the following command to ping the computer running the TFTP server. For example, if the IP address of the TFTP server is 192.168.1.168:

   ```
   execute ping 192.168.1.168
   ```

6. Enter the following command to restart the FortiGate unit.

   ```
   execute reboot
   ```

   The FortiGate unit responds with the following message:

   ```
   This operation will reboot the system!
   Do you want to continue? (y/n)
   ```

7. Type `y`.

   As the FortiGate unit starts, a series of system startup messages appears. When the following messages appears:

   ```
   Press any key to display configuration menu.....
   ```

Immediately press any key to interrupt the system startup.

You have only 3 seconds to press any key. If you do not press a key soon enough, the FortiGate unit reboots and you must log in and repeat the execute reboot command.

If you successfully interrupt the startup process, the following messages appears:

```
[G]: Get firmware image from TFTP server.
[F]: Format boot device.
[B]: Boot with backup firmware and set as default
[C]: Configuration and information
[Q]: Quit menu and continue to boot with default firmware.
[H]: Display this list of options.
Enter G, F, Q, or H:
```

8. Type **G** to get to the new firmware image form the TFTP server.

   The following message appears:

   ```
   Enter TFTP server address [192.168.1.168]:
   ```

9. Type the address of the TFTP server and press **Enter**.

   The following message appears:

   ```
   Enter Local Address [192.168.1.188]:
   ```

10. Type an IP address the FortiGate unit can use to connect to the TFTP server. The IP address can be any IP address that is valid for the network the interface is connected to.

Make sure you do not enter the IP address of another device on this network.

The following message appears:

```
Enter File Name [image.out]:
```

11. Enter the firmware image filename and press **Enter**.

    The TFTP server uploads the firmware image file to the FortiGate unit and a message similar to the following appears:

    ```
    Save as Default firmware/Backup firmware/Run image without saving: [D/B/R]
    ```

12. Type `D`.

    The FortiGate unit installs the new firmware image and restarts. The installation might take a few minutes to complete.

Restore from a USB key - CLI

To restore configuration using the CLI

1. Log into the CLI.
2. Enter the following command to restore an unencrypted configuration file:

   ```
   exec restore image usb <filename>
   ```

   If your configuration file was encrypted, enter the following command:

   ```
   execute restore config usb-mode <password>
   ```

   The FortiGate unit responds with the following message:

   ```
   This operation will replace the current firmware version!
   Do you want to continue? (y/n)
   ```

3. Type `y`.

Reverting to a previous firmware version - CLI

This procedure reverts the FortiGate unit to its factory default configuration and deletes IPS custom signatures, web content lists, email filtering lists, and changes to replacement messages.

Before beginning this procedure, it is recommended that you:

- back up the FortiGate unit system configuration using the command `execute backup config`
- back up the IPS custom signatures using the command `execute backup ipsuserdefsig`
- back up web content and email filtering lists

To use the following procedure, you must have a TFTP server the FortiGate unit can connect to.

To revert to a previous firmware version using the CLI

1. Make sure the TFTP server is running
2. Copy the firmware image file to the root directory of the TFTP server.
3. Log into the FortiGate CLI.
4. Make sure the FortiGate unit can connect to the TFTP server execute by using the `execute ping` command.
5. Enter the following command to copy the firmware image from the TFTP server to the FortiGate unit:

   ```
   execute restore image tftp <name_str> <tftp_ipv4>
   ```

   Where `<name_str>` is the name of the firmware image file and `<tftp_ipv4>` is the IP address of the TFTP server. For example, if the firmware image file name is `imagev28.out` and the IP address of the TFTP server is 192.168.1.168, enter:

   ```
   execute restore image tftp image28.out 192.168.1.168
   ```

   The FortiGate unit responds with this message:

   ```
   This operation will replace the current firmware version!
       Do you want to continue? (y/n)
   ```
6. Type `y`.

   The FortiGate unit uploads the firmware image file. After the file uploads, a message similar to the following appears:

   ```
   Get image from tftp server OK.
   Check image OK.
   This operation will downgrade the current firmware version!
   Do you want to continue? (y/n)
   ```
7. Type `y`.
8. The FortiGate unit reverts to the old firmware version, resets the configuration to factory defaults, and restarts. This process takes a few minutes.
9. Reconnect to the CLI.
10. To restore your previous configuration, if needed, use the command:

    ```
    execute restore config <name_str> <tftp_ipv4>
    ```
11. Update antivirus and attack definitions using the command:

    ```
    execute update-now.
    ```

Configuration revision

The **System Configuration > Revisions** option in the **System Information** widget enables you to manage multiple versions of configuration files on models that have a 512 flash memory and higher. Revision control requires either a configured central management server or the local hard drive, if the model of your FortiGate has this feature. Typically, configuration backup to local drive is not available on lower-end models.

The central management server can either be a FortiManager unit or FortiCloud.

If central management is not configured on your FortiGate unit, a message appears to tell you to do one of the following:

- enable central management
- obtain a valid license.

When revision control is enabled on your FortiGate unit, and configurations backups have been made, a list of saved revisions of those backed-up configurations appears.

Configuration revisions are viewed in the **System Information** widget on the Dashboard.

Controlled upgrade

Using a controlled upgrade, you can upload a new version of the FortiOS firmware to a separate partition in the FortiGate memory for later upgrade. The FortiGate unit can also be configured so that when it is rebooted, it will automatically load the new firmware (CLI only). Using this option, you can stage a number of FortiGate units to do an upgrade simultaneously to all devices using FortiManager or script.

To load the firmware for later installation - GUI

1. Go to **Dashboard**.
2. Under **System Information > Firmware Version**, select **Update**.
3. Type the path and filename of the firmware image file, or select **Browse** and locate the file.
4. Deselect the **Boot the New Firmware** option.
5. Select **OK**.

To load the firmware for later installation - CLI

```
execute restore secondary-image {ftp | tftp | usb}
```

To set the FortiGate unit so that when it reboots, the new firmware is loaded, use the CLI command…

```
execute set-next-reboot {primary | secondary}
```

... where `{primary | secondary}` is the partition with the preloaded firmware.

To trigger the upgrade using the GUI

1. Go to **> Dashboard**.
2. Under **System Information > Firmware Version**, select **Details**.
3. Select the check box for the new firmware version.
   The **Comments** column indicates which firmware version is the current active version.
4. Select **Upgrade** icon.

Configuration Backups

Once you successfully configure the FortiGate, it is extremely important that you backup the configuration. In some cases, you may need to reset the FortiGate to factory defaults or perform a TFTP upload of the firmware, which will erase the existing configuration. In these instances, the configuration on the device will have to be recreated, unless a backup can be used to restore it. You should also backup the local certificates, as the unique SSL inspection CA and server certificates that are generated by your FortiGate by default are not saved in a system backup.

It is also recommended that you backup the configuration after *any* future changes are made, to ensure you have the most current configuration available. Also, backup the configuration before any upgrades of the FortiGate's firmware. Should anything happen to the configuration during the upgrade, you can easily restore the saved configuration.

Always backup the configuration and store it on the management computer or off-site. You have the option to save the configuration file to various locations including the local PC, USB key, FTP and TFTP site.The last two are configurable through the CLI only.

If you have VDOMs, you can back up the configuration of the entire FortiGate or only a specific VDOM. Note that if you are using FortiManager or FortiCloud, full backups are performed and the option to backup individual VDOMs will not appear.

Backing up the configuration using the GUI

1. Go to the **Dashboard** and locate the **System Information** widget.
2. Beside **System Configuration**, select **Backup**.
3. Direct the backup to your **Local PC** or to a **USB key**.
   The **USB Disk** option will be grayed out if no USB drive is inserted in the USB port. You can also backup to the FortiManager using the CLI.
4. If VDOMs are enabled, select to backup the entire FortiGate configuration (**Full Config**) or only a specific VDOM configuration (**VDOM Config**).
5. If backing up a VDOM configuration, select the VDOM name from the list.
6. Select **Encrypt configuration file**.
   Encryption must be enabled on the backup file to back up VPN certificates.
7. Enter a password and enter it again to confirm it. You will need this password to restore the file.
8. Select **Backup**.
9. The web browser will prompt you for a location to save the configuration file. The configuration file will have a .conf extension.

Backing up the configuration using the CLI

Use the following command:

```
execute backup config management-station <comment>
```

… or …

```
execute backup config usb <backup_filename> [<backup_password>]
```

… or for FTP, note that port number, username are optional depending on the FTP site…

```
execute backup config ftp <backup_filename> <ftp_server> [<port>] [<user_name>]
    [<password>]
```

… or for TFTP …

```
execute backup config tftp <backup_filename> <tftp_servers> <password>
```

Use the same commands to backup a VDOM configuration by first entering the commands:

```
config vdom
   edit <vdom_name>
```

Backup and restore the local certificates

This procedure exports a server (local) certificate and private key together as a password protected PKCS12 file. The export file is created through a customer-supplied TFTP server. Ensure that your TFTP server is running and accessible to the FortiGate before you enter the command.

Backing up the local certificates

Connect to the CLI and use the following command:

```
execute vpn certificate local export tftp <cert_name> <filename> <tftp_ip>
```

where:

- `<cert_name>` is the name of the server certificate.
- `<filename>` is a name for the output file.
- `<tftp_ip>` is the IP address assigned to the TFTP server host interface.

Restoring the local certificates - GUI

1. Move the output file from the TFTP server location to the management computer.
2. Go to **System > Certificates** and select **Import**.
3. Select the appropriate **Type** of certificate and fill in any required fields.
4. Select **Browse**. Browse to the location on the management computer where the exported file has been saved, select the file and select **Open**.
5. If required, enter the **Password** needed to upload the exported file.
6. Select **OK**.

Restoring the local certificates - CLI

Connect to the CLI and use the following command:

```
execute vpn certificate local import tftp <filename> <tftp_ip>
```

Backup and restore a configuration file using SCP

You can use secure copy protocol (SCP) to download the configuration file from the FortiGate as an alternative method of backing up the configuration file or an individual VDOM configuration file. This is done by enabling SCP for and administrator account and enabling SSH on a port used by the SCP client application to connect to the FortiGate. SCP is enabled using the CLI commands:

```
config system global
   set admin-scp enable
```

```
end
```

Use the same commands to backup a VDOM configuration by first entering the commands:

```
config global
   set admin-scp enable
end
config vdom
   edit <vdom_name>
```

Enable SSH access on the interface

SCP uses the SSH protocol to provide secure file transfer. The interface you use for administration must allow SSH access.

To enable SSH - GUI:

1. Go to **Network > Interfaces**.
2. Select the interface you use for administrative access and select **Edit**.
3. In the **Administrative Access** section, select **SSH**.
4. Select **OK**.

To enable SSH - CLI:

```
config system interface
   edit <interface_name>
      set allowaccess ping https ssh
end
```

When adding to, or removing a protocol, you must type the entire list again. For example, if you have an access list of HTTPS and SSH, and you want to add PING, typing:

```
set allowaccess ping
```

...only PING will be set. In this case, you must type...

```
set allowaccess https ssh ping
```

Using the SCP client

The FortiGate downloads the configuration file as `sys_conf`. Use the following syntax to download the file:

Linux

```
scp admin@<FortiGate_IP>:fgt-config <location>
```

Windows

```
pscp admin@<FortiGate_IP>:fgt-config <location>
```

The following examples show how to download the configuration file from a FortiGate-100D, at IP address 172.20.120.171, using Linux and Windows SCP clients.

Linux client example

To download the configuration file to a local directory called `~/config`, enter the following command:

```
scp admin@172.20.120.171:fgt-config ~/config
```

Enter the admin password when prompted.

Windows client example

To download the configuration file to a local directory called c:\config, enter the following command in a Command Prompt window:

```
pscp admin@172.20.120.171:fgt-config c:\config
```

Enter the admin password when prompted.

SCP public-private key authentication

SCP authenticates itself to the FortiGate in the same way as an administrator using SSH accesses the CLI. Instead of using a password, you can configure the SCP client and the FortiGate with a public-private key pair.

To configure public-private key authentication

1. Create a public-private key pair using a key generator compatible with your SCP client.
2. Save the private key to the location on your computer where your SSH keys are stored.
   This step depends on your SCP client. The Secure Shell key generator automatically stores the private key.
3. Copy the public key to the FortiGate using the CLI commands:

   ```
   config system admin
      edit admin
         set ssh-public-key1 "<key-type> <key-value>"
      end
   ```

   `<key-type>` must be the ssh-dss for a DSA key or ssh-rsa for an RSA key. For the `<key-value>`, copy the public key data and paste it into the CLI command.

   If you are copying the key data from Windows Notepad, copy one line at a time and ensure that you paste each line of key data at the end of the previously pasted data. As well:

   - Do not copy the end-of-line characters that appear as small rectangles in Notepad.
   - Do not copy the `---- BEGIN SSH2 PUBLIC KEY ---- or Comment: "[2048-bit dsa,...]"` lines.
   - Do not copy the `---- END SSH2 PUBLIC KEY ----` line.
4. Type the closing quotation mark and press **Enter**.

Your SCP client can now authenticate to the FortiGate based on SSH keys rather than the administrator password.

Restoring a configuration using SCP

To restore the configuration using SCP, use the commands:

```
scp <local_file> <admin_user>@<FGT_IP>:fgt-restore-config
```

To use this command/method of restoring the FortiGate configuration, you need to log in as the “admin” administrator.

Restoring a configuration

Should you need to restore a configuration file, use the following steps:

To restore the FortiGate configuration - GUI

1. Go to the **Dashboard** and locate the **System Information** widget.
2. Beside **System Configuration**, select **Restore**.
3. Select to upload the configuration file to be restored from your **Local PC or a USB key**.
   The **USB Disk** option will be grayed out if no USB drive is inserted in the USB port. You can restore from the FortiManager using the CLI.
4. Enter the path and file name of the configuration file, or select **Browse** to locate the file.
5. Enter a password if required.
6. Select **Restore**.

To back up the FortiGate configuration - CLI

```
execute restore config management-station normal 0
```

… or …

```
execute restore config usb <filename> [<password>]
```

… or for FTP, note that port number, username are optional depending on the FTP site…

```
execute backup config ftp <backup_filename> <ftp_server> [<port>] [<user_
    name>] [<password>]
```

… or for TFTP …

```
execute backup config tftp <backup_filename> <tftp_server> <password>
```

The FortiGate will load the configuration file and restart. Once the restart has completed, verify that the configuration has been restored.

Configuration revision

The **System Configuration > Revisions** option in the **System Information** widget enables you to manage multiple versions of configuration files on models that have a 512 flash memory and higher. Revision control requires either a configured central management server or the local hard drive, if the model of your FortiGate has this feature. Typically, configuration backup to local drive is not available on lower-end models.

The central management server can either be a FortiManager unit or FortiCloud.

If central management is not configured on your FortiGate unit, a message appears to tell you to do one of the following:

- enable central management
- obtain a valid license.

When revision control is enabled on your FortiGate unit, and configurations backups have been made, a list of saved revisions of those backed-up configurations appears.

Configuration revisions are viewed in the **System Information** widget on the Dashboard.

Restore factory defaults

There may be a point where need to reset the FortiGate to its original defaults; for example, to begin with a fresh configuration. There are two options when restoring factory defaults. The first resets the entire device to the original out-of-the-box configuration:

To reset the FortiGate to its factory default settings - GUI

1. Go to the **Dashboard** and locate the **System Information** widget.
2. Beside **System Configuration**, select **Restore**.
3. Select **Restore Factory Defaults** at the top of the page.

You can reset using the CLI by entering the command:

```
execute factoryreset
```

When prompted, type `y` to confirm the reset.

Alternatively, in the CLI you can reset the factory defaults but retain the interface and VDOM configuration.

Use the command:

```
execute factoryreset2
```

FortiGuard

The FortiGuard Distribution Network (FDN) of servers provides updates to antivirus, antispam and IPS definitions to your FortiGate. Worldwide coverage of FortiGuard services is provided by FortiGuard service points. FortiGuard Subscription Services provide comprehensive Unified Threat Management (UTM) security solutions to enable protection against content and network level threats.

The FortiGuard team can be found around the globe, monitoring virus, spyware and vulnerability activities. As vulnerabilities are found, signatures are created and pushed to the subscribed FortiGates. The Global Threat Research Team enables Fortinet to deliver a combination of multi-layered security intelligence and provide true zero-day protection from new and emerging threats.The FortiGuard Network has data centers around the world located in secure, high availability locations that automatically deliver updates to the Fortinet security platforms to and protect the network with the most up-to-date information.

The FortiGuard services provide a number of services to monitor world-wide activity and provide the best possible security:

- **Intrusion Prevention** System (IPS) - The FortiGuard Intrusion Prevention System (IPS) uses a customizable database of more than 4000 known threats to stop attacks that evade conventional firewall defenses. It also provides behavior-based heuristics, enabling the system to recognize threats when no signature has yet been developed. It also provides more than 1000 application identity signatures for complete application control.
- **Application Control** - Application Control allows you to identify and control applications on networks and endpoints regardless of port, protocol, and IP address used. It gives you unmatched visibility and control over application traffic, even traffic from unknown applications and sources.
- **AntiVirus** -The FortiGuard AntiVirus Service provides fully automated updates to ensure protection against the latest content level threats. It employs advanced virus, spyware, and heuristic detection engines to prevent both new and evolving threats from gaining access to your network and protects against vulnerabilities.
- **Web Filtering** - Web Filtering provides Web URL filtering to block access to harmful, inappropriate, and dangerous web sites that may contain phishing/pharming attacks, malware such as spyware, or objectionable content that can expose your organization to legal liability. Based on automatic research tools and targeted research analysis, real-time updates enable you to apply highly-granular policies that filter web access based on 78 web content categories, over 45 million rated web sites, and more than two billion web pages - all continuously updated.
- **Vulnerability Scanning** - FortiGuard Services provide comprehensive and continuous updates for vulnerabilities, remediation, patch scan, and configuration benchmarks.
- **Email Filtering** - The FortiGuard Antispam Service uses both a sender IP reputation database and a spam signature database, along with sophisticated spam filtering tools on Fortinet appliances and agents, to detect and block a wide range of spam messages. Updates to the IP reputation and spam signature databases are provided continuously via the FDN.
- **Messaging Services** - Messaging Services allow a secure email server to be automatically enabled on your FortiGate to send alert email or send email authentication tokens. With the SMS gateway, you can enter phone numbers where the FortiGate will send the SMS messages. Note that depending on your carrier, there may be a slight time delay on receiving messages.
- **DNS and DDNS** - The FortiGuard DNS and DDNS services provide an efficient method of DNS lookups once subscribed to the FortiGuard network. This is the default option. The FortiGate connects automatically to the FortiGuard DNS server. If you do not register, you need to configure an alternate DNS server.

  Configure the DDNS server settings using the CLI commands:

```
config system fortiguard
   set ddns-server-ip
```

```
    set ddns-server-port
end
```

Support Contract and FortiGuard Subscription Services

The **Support Contract** and **FortiGuard Subscription Services** sections are displayed in abbreviated form within the **License Information** widget. A detailed version is available by going to **System > FortiGuard**.

The Support Contract area displays the availability or status of your FortiGate's support contract. The status displays can be either **Unreachable, Not Registered,** or **Valid Contract**.

The FortiGuard Subscription Services area displays detailed information about your FortiGate's support contract and FortiGuard subscription services. On this page, you can also manually update the antivirus and IPS engines.

The status icons for each section Indicates the state of the subscription service. The icon corresponds to the availability description.

- **Gray (Unreachable)** – the FortiGate is not able to connect to service.
- **Orange (Not Registered)** – the FortiGate can connect, but not subscribed.
- **Yellow (Expired)** – the FortiGate had a valid license that has expired.
- **Green (Valid license)** – the FortiGate can connect to FDN and has a registered support contract. If the Status icon is green, the expiry date also appears.

Verifying your Connection to FortiGuard

If you are not getting FortiGuard web filtering or antispam services, there are a few things to verify communication to the FortiGuard Distribution Network (FDN) is working. Before any troubleshooting, ensure that the FortiGate has been registered and you or your company, has subscribed to the FortiGuard services.

Verification - GUI

The simplest method to check that the FortiGate is communicating with the FDN, is to check the **License Information** dashboard widget. Any subscribed services should have a green check mark beside them indicating that connections are successful. Any other icon indicates a problem with the connection, or you are not subscribed to the FortiGuard services.

You can also view the FortiGuard connection status by going to **System > FortiGuard**.

Verification - CLI

You can also use the CLI to see what FortiGuard servers are available to your FortiGate. Use the following CLI command to ping the FDN for a connection:

```
ping guard.fortinet.net
```

You can also use diagnose command to find out what FortiGuard servers are available:

```
diagnose debug rating
```

From this command, you will see output similar to the following:

```
Locale : english
License : Contract
Expiration : Sun Jul 24 20:00:00 2011
Hostname : service.fortiguard.net
-=- Server List (Tue Nov 2 11:12:28 2010) -=-
```

```
IP Weight       RTT Flags  TZ   Packets   Curr Lost   Total Lost
69.20.236.180  0   10     -5   77200 0           42
69.20.236.179  0   12     -5   52514     0            34
66.117.56.42   0   32     -5   34390     0 62
80.85.69.38    50  164     0   34430     0            11763
208.91.112.194 81  223 D  -8   42530     0            8129
216.156.209.26 286 241 DI -8   55602     0           21555
```

An extensive list of servers are available. Should you see a list of three to five available servers, the FortiGuard servers are responding to DNS replies to service.FortiGuard.net, but the INIT requests are not reaching FDS services on the servers.

The rating flags indicate the server status:

D	Indicates the server was found via the DNS lookup of the hostname. If the hostname returns more than one IP address, all of them will be flagged with 'D' and will be used first for INIT requests before falling back to the other servers.
I	Indicates the server to which the last INIT request was sent
F	The server has not responded to requests and is considered to have failed.
T	The server is currently being timed.

The server list is sorted first by weight and then the server with the smallest RTT is put at the top of the list, regardless of weight. When a packet is lost, it will be resent to the next server in the list.

The weight for each server increases with failed packets and decreases with successful packets. To lower the possibility of using a faraway server, the weight is not allowed to dip below a base weight, which is calculated as the difference in hours between the FortiGate and the server multiplied by 10. The further away the server is, the higher its base weight and the lower in the list it will appear.

Port assignment

FortiGates contact the FortiGuard Distribution Network (FDN) for the latest list of FDN servers by sending UDP packets with typical source ports of 1027 or 1031, and destination ports of 53 or 8888. The FDN reply packets have a destination port of 1027 or 1031.

If your ISP blocks UDP packets in this port range, the FortiGate cannot receive the FDN reply packets. As a result, the FortiGate will not receive the complete FDN server list.

If your ISP blocks the lower range of UDP ports (around 1024), you can configure your FortiGate to use higher-numbered ports, using the CLI command…

```
config system global
   set ip-src-port-range <start port>-<end port>
end
```

…where the `<start port>` and `<end port>` are numbers ranging of 1024 to 25000.

For example, you could configure the FortiGate to not use ports lower than 2048 or ports higher than the following range:

```
config system global
   set ip-src-port-range 2048-20000
```

```
end
```

Trial and error may be required to select the best source port range. You can also contact your ISP to determine the best range to use. Push updates might be unavailable if:

- there is a NAT device installed between the unit and the FDN
- your unit connects to the Internet using a proxy server.

FortiCloud is a hosted security management and log retention service for FortiGate products. It gives you a centralized reporting, traffic analysis, configuration and log retention without the need for additional hardware and software.

Sending malware statistics to FortiGuard

To support following Malware trends and making zero-day discoveries, FortiGate units send encrypted statistics to FortiGuard about IPS, Application Control, and AntiVirus events detected by the FortiGuard services running on your FortiGate. FortiGuard uses the statistics collected to achieve a balance between performance and security effectiveness by moving inactive signatures to an extended signature database.

The statistics include some non-personal information that identifies your FortiGate and its country. The information is never shared with external parties. You can choose to disable the sharing of this information by entering the following CLI command.

```
config system global
   set fds-statistics disable
end
```

Configuring AntiVirus and IPS Options

Go to **System > FortiGuard**, and expand the **AV and IPS Options** section to configure the antivirus and IPS options for connecting and downloading definition files.

Use override server address	Select to configure an override server if you cannot connect to the FDN or if your organization provides updates using their own FortiGuard server.
Allow Push Update	Select to allow updates sent automatically to your FortiGate when they are available
Allow Push Update status icon	The status of the FortiGate for receiving push updates: • **Gray (Unreachable)** - the FortiGate is not able to connect to push update service • **Yellow (Not Available)** - the push update service is not available with your current support license • **Green (Available)** - the push update service is allowed.

	Available only if both **Use override server address** and **Allow Push Update** are enabled.
Use override push IP and Port	Enter the IP address and port of the NAT device in front of your FortiGate. FDS will connect to this device when attempting to reach the FortiGate. The NAT device must be configured to forward the FDS traffic to the FortiGate on UDP port 9443.
Schedule Updates	Select this check box to enable updates to be sent to your FortiGate at a specific time. For example, to minimize traffic lag times, you can schedule the update to occur on weekends or after work hours. Note that a schedule of once a week means any urgent updates will not be pushed until the scheduled time. However, if there is an urgent update required, select the **Update Now** button.
Update Now	Select to manually initiate an FDN update.
Submit attack characteristics… (recommended)	Select to help Fortinet maintain and improve IPS signatures. The information sent to the FortiGuard servers when an attack occurs and can be used to keep the database current as variants of attacks evolve.

Manual updates

To manually update the signature definitions file, you need to first go to the Support web site at https://support.fortinet.com. Once logged in, select FortiGuard Service Updates from the Download area of the web page. The browser will present you the most current antivirus and IPS signature definitions which you can download.

Once downloaded to your computer, log into the FortiGate to load the definition file.

To load the definition file onto the FortiGate

1. Go to **System > FortiGuard**.
2. Select the **Update** link for either **AV Definitions or IPS Definitions**.
3. Locate the downloaded file and select **OK**.

The upload may take a few minutes to complete.

Automatic updates

The FortiGate can be configured to request updates from the FortiGuard Distribution Network. You can configure this to be on a scheduled basis, or with push notifications.

Scheduling updates

Scheduling updates ensures that the virus and IPS definitions are downloaded to your FortiGate on a regular basis, ensuring that you do not forget to check for the definition files yourself. Note that updating definitions can cause a very short disruption in traffic currently being scanned while the FortiGate unit applies the new signature database. Schedule updates during off-peak hours, such as evenings or weekends, when network usage is minimal, ensures that the network activity will not suffer from the added traffic of downloading the definition files.

To enable scheduled updates - GUI

1. Go to **System > FortiGuard**.
2. Click the Expand Arrow for **AV and IPS Options**.
3. Select the **Scheduled Update** check box.
4. Select the frequency of the updates and when within that frequency.
5. Select **Apply**.

To enable scheduled updates - CLI

```
config system autoupdate schedule
   set status enable
   set frequency {every | daily | weekly}
   set time <hh:mm>
   set day <day_of_week>
end
```

Push updates

Push updates enable you to get immediate updates when new virus or intrusions have been discovered and new signatures are created. This ensures that when the latest signature is available it will be sent to the FortiGate.

When a push notification occurs, the FortiGuard server sends a notice to the FortiGate that there is a new signature definition file available. The FortiGate then initiates a download of the definition file, similar to the scheduled update.

To ensure maximum security for your network, you should have a scheduled update as well as enable the push update, in case an urgent signature is created, and your cycle of the updates only occurs weekly.

To enable push updates - GUI

1. Go to **System > FortiGuard**.
2. Click the Expand Arrow for **AV and IPS Options**.
3. Select **Allow Push Update**.
4. Select **Apply**.

To enable push updates - CLI

```
config system autoupdate push-update
   set status enable
end
```

Push IP override

If the FortiGate is behind another NAT device (or another FortiGate), to ensure it receives the push update notifications, you need to use an override IP address for the notifications. To do this, you create a virtual IP to map to the external port of the NAT device.

Generally speaking, if there are two FortiGate devices as in the diagram below, the following steps need to be completed on the FortiGate NAT device to ensure the FortiGate on the internal network receives the updates:

- Add a port forwarding virtual IP to the FortiGate NAT device that connects to the Internet by going to **Firewall Objects > Virtual IP**.

- Add a security policy to the FortiGate NAT device that connects to the Internet that includes the port forwarding virtual IP.
- Configure the FortiGate on the internal network with an override push IP and port.

On the FortiGate internal device, the virtual IP is entered as the **Use push override IP** address.

To enable push update override- GUI

1. Go to **System > FortiGuard**.
2. Under **AntiVirus & IPS Updates**, enable **Accept Push Updates**.
3. Enable **Use override push**.
4. Enter the virtual IP address configured on the NAT device.
5. Select **Apply**.

To enable push updates - CLI

```
config system autoupdate push-update
   set status enable
   set override enable
   set address <vip_address>
end
```

Configuring Web Filtering and Email Filtering Options

Go to **System > FortiGuard**, and expand arrow to view **Web Filtering and Email Filtering Options** for setting the size of the caches and ports used.

Web Filter cache TTL	Set the Time To Live value. This is the number of seconds the FortiGate will store a blocked IP or URL locally, saving time and network access traffic, checking the FortiGuard server. Once the TTL has expired, the FortiGate will contact an FDN server to verify a web address. The TTL must be between 300 and 86400 seconds.
Antispam cache TTL	Set the Time To Live value. This is the number of seconds the FortiGate will store a blocked IP or URL locally, saving time and network access traffic, checking the FortiGuard server. Once the TTL has expired, the FortiGate will contact an FDN server to verify a web address. The TTL must be between 300 and 86400 seconds.
Port Section	Select the port assignments for contacting the FortiGuard servers. Select the **Test Availability** button to verify the connection using the selected port.
To have a URL's category rating re-evaluated, please click here	Select to re-evaluate a URL's category rating on the FortiGuard Web Filter service.

Email filtering

The FortiGuard data centers monitor and update email databases of known spam sources. With FortiGuard Anti-Spam filtering enabled, the FortiGate verifies incoming email sender address and IPs against the database, and

take the necessary action as defined within the antivirus profiles.

Spam source IP addresses can also be cached locally on the FortiGate, providing a quicker response time, while easing load on the FortiGuard servers, aiding in a quicker response time for less common email address requests.

By default, the antispam cache is enabled. The cache includes a time-to-live (TTL) value, which is the amount of time an email address will stay in the cache before expiring. You can change this value to shorten or extend the time between 5 and 1,440 minutes.

To modify the antispam cache TTL - GUI

1. Go to **System > FortiGuard**.
2. Under **Filtering**, enable **Anti-Spam Cache**.
3. Enter the TTL value in minutes.
4. Select **Apply**.

To modify the Anti-Spam filter TTL - CLI

```
config system fortiguard
   set antispam-cache-ttl <integer>
end
```

Further antispam filtering options can be configured to block, allow or quarantine, specific email addresses. These configurations are available through the **Security Profiles > Antispam** menu. For more information, see the Security Profiles handbookchapter.

Online Security Tools

The FortiGuard online center provides a number of online security tools that enable you to verify or check ratings of web sites, email addresses as well as check file for viruses:

- **URL lookup** - By entering a web site address, you can see if it has been rated and what category and classification it is filed as. If you find your web site or a site you commonly go to has been wrongly categorized, you can use this page to request that the site be re-evaluated.
  https://fortiguard.com/webfilter
- **IP and signature lookup** - The IP and signature lookup enables you to check whether an IP address is blacklisted in the FortiGuard IP reputation database or whether a URL or email address is in the signature database.
  https://fortiguard.com/webfilter
- **Online virus scanner** - If you discover a suspicious file on your machine, or suspect that a program you downloaded from the Internet might be malicious you can scan it using the FortiGuard online scanner. The questionable file can be uploaded from your computer to a dedicated server where it will be scanned using FortiClient Antivirus. Only one file of up to 1 MB can be checked at any one time. All files will be forwarded to our research labs for analysis.
  https://fortiguard.com/virusscanner
- **Malware removal tools** - FortiGuard Labs developed and maintains tools to disable and remove the specific malware and related variants. Some tools have been developed to remove specific malware, often tough to remove. A universal cleaning tool, FortiCleanup, is also available for download.
  The FortiCleanup is a tool developed to identify and cleanse systems of malicious rootkit files and their associated malware. Rootkits consist of code installed on a system with kernel level privileges, often used to hide malicious files, keylog and thwart detection / security techniques. The aim of this tool is to reduce the effectiveness of such malware by finding and eliminating rootkits. The tool offers a quick memory scan as well as a full system scan.

FortiCleanup will not only remove malicious files, but also can cleanse registry entries, kernel module patches, and other tricks commonly used by rootkits - such as SSDT hooks and process enumeration hiding.
A license to use these applications is provided free of charge, courtesy of Fortinet.

FortiCloud

FortiCloud is a hosted security management and log retention service for FortiGate devices. It gives you centralized reporting, traffic analysis, configuration management and log retention without the need for additional hardware and software.

FortiCloud offers a wide range of features:

- **Simplified central management** FortiCloud provides a central web-based management console to manage individual or aggregated FortiGate and FortiWiFi devices. Adding a device to the FortiCloud management subscription is straightforward. FortiCloud has detailed traffic and application visibility across the whole network.
- **Hosted log retention with large default storage allocated** Log retention is an integral part of any security and compliance program but administering a separate storage system is burdensome. FortiCloud takes care of this automatically and stores the valuable log information in the cloud. Each device is allowed up to 200Gb of log retention storage. Different types of logs can be stored including Traffic, System Events, Web, Applications and Security Events.
- **Monitoring and alerting in real time** Network availability is critical to a good end-user experience. FortiCloud enables you to monitor your FortiGate network in real time with different alerting mechanisms to pinpoint potential issues. Alerting mechanisms can be delivered via email.
- **Customized or pre-configured reporting and analysis tools** Reporting and analysis are your eyes and ears into your network's health and security. Pre-configured reports are available, as well as custom reports that can be tailored to your specific reporting and compliance requirements. For example, you may want to look closely at application usage or web site violations. The reports can be emailed as PDFs and can cover different time periods.
- **Maintain important configuration information uniformly** The correct configuration of the devices within your network is essential to maintaining an optimum performance and security posture. In addition, maintaining the correct firmware (operating system) level allows you to take advantage of the latest features.
- **Service security** - All communication (including log information) between the devices and the clouds is encrypted. Redundant data centers are always used to give the service high availability. Operational security measures have been put in place to make sure your data is secure — only you can view or retrieve it.

Registration and Activation

Before you can activate a FortiCloud account, you must first register your device.

FortiCloud accounts can be registered manually through the FortiCloud website, https://www.forticloud.com, but you can easily register and activate your account directly from your FortiGate.

Activating your FortiCloud Account

1. On your device's dashboard, in the License Information widget, select the **Activate** button in the FortiCloud section.
2. A dialogue asking you to register your FortiCloud account will appear. Enter your information, view and accept the Terms and Conditions and select **Create Account**.
3. A second dialogue window will appear, asking you to enter your information to confirm your account. This will send a confirmation email to your registered email. The dashboard widget will update to show that confirmation is required.
4. Open your email, and follow the confirmation link contained in it.

Results

A FortiCloud page will open, stating that your account has been confirmed. The Activation Pending message on the dashboard will change to state the type of account you have ('1Gb Free' or '200Gb Subscription'), and will now provide a link to the FortiCloud portal.

Enabling logging to FortiCloud

1. Go to **Log & Report > Log Settings**.
2. Enable **Send Logs to FortiCloud.**
3. Select **Test Connectivity** to ensure that your FortiGate can connect to the registered FortiCloud account.
4. Under **GUI Preferences**, set **Display Logs from FortiCloud**, to see FortiCloud logs within the FortiGate's GUI.

Logging into the FortiCloud portal

Once logging has been configured and you have registered your account, you can log into the FortiCloud portal and begin viewing your logging results. There are two methods to reach the FortiCloud portal:

- If you have direct networked access to the FortiGate, you can simply open your Dashboard and check the License Information widget. Next to the current FortiCloud connection status will be a link to reach the FortiCloud Portal.
- If you do not currently have access to the FortiGate's interface, you can visit the FortiCloud website (https://forticloud.com) and log in remotely, using your email and password. It will ask you to confirm the FortiCloud account you are connecting to and then you will be granted access. Connected devices can be remotely configured using the Scripts page in the Management Tab, useful if an administrator may be away from the unit for a long period of time.

Cloud Sandboxing

FortiCloud can be used for automated sample tracking, or sandboxing, for files from a FortiGate. This allows suspicious files to be sent to be inspected without risking network security. If the file exhibits risky behavior, or is found to contain a virus, a new virus signature is created and added to the FortiGuard antivirus signature database.

Cloud sandboxing is configured by going to **System > Cooperative Security Fabric**. After enabling sandbox inspection, select **Activate FortiSandbox Cloud.**

Sandboxing results will be shown in a new tab called **AV Submissions** in the FortiCloud portal. This tab will only appear after a file has been sent for sandboxing.

For more information about FortiCloud, see the FortiCloud documentation.

Next Steps

Here's a list of some resources you can check out next to help you get the most out of your newly installed and configured FortiGate.

Best Practices

The Best Practices document is a collection of guidelines to ensure the most secure and reliable operation of FortiGates in a customer environment. It is updated periodically as new issues are identified.

This document can be found at http://docs.fortinet.com/.

The Fortinet Cookbook

The Fortinet Cookbook contains a variety of step-by-step examples of how to integrate a FortiGate into your network and apply features such as security profiles, wireless networking, and VPN.

Using the Cookbook, you can go from idea to execution in simple steps, configuring a secure network for better productivity with reduced risk.

The Fortinet Cookbook can be found at http://cookbook.fortinet.com.

The Fortinet Video Library

The Fortinet Video Library contains video tutorials showing how to configure various Fortinet products, including FortiGates. Many FortiGate videos are based on recipes from the FortiGate Cookbook.

The Fortinet Video Library can be found at http://video.fortinet.com. You can also subscribe to Fortinet's YouTube channel.

The FortiOS Handbook

The FortiOS Handbook is the complete guide to FortiOS, covering a variety of FortiGate configurations. The Handbook is available as a single complete document online. Handbook chapters are also available as standalone documents.

The FortiOS Handbook can be found at http://docs.fortinet.com/.

Chapter 3 - Advanced Routing

This chapter describes advanced static routing concepts and how to implement dynamic routing on FortiGate units.

This FortiOS Handbook chapter contains the following sections:

Advanced Static Routing explains universal and static routing concepts, equal cost multipath (ECMP) and load balancing, policy routing, and routing in transparent mode.

Dynamic Routing Overview provides an overview of dynamic routing, compares static and dynamic routing, and helps you decide which dynamic routing protocol is best for you.

Routing Information Protocol (RIP) describes a distance-vector routing protocol intended for small, relatively homogeneous networks.

Border Gateway Protocol (BGP) describes classless inter-domain routing, and aggregate routes. BGP is the only routing protocol to use TCP for a transport protocol.

Open Shortest Path First (OSPF) provides background on the specific protocol explaining terms used and how the protocol works, as well as providing some troubleshooting information and examples on configuring the protocols in different situations.

Intermediate System to Intermediate System Protocol(IS-IS), which describes the link state protocol, is well-suited to smaller networks and with near universal support on routing hardware. The section also provides troubleshooting information and configuration examples.

What's new for networking in FortiOS 5.4

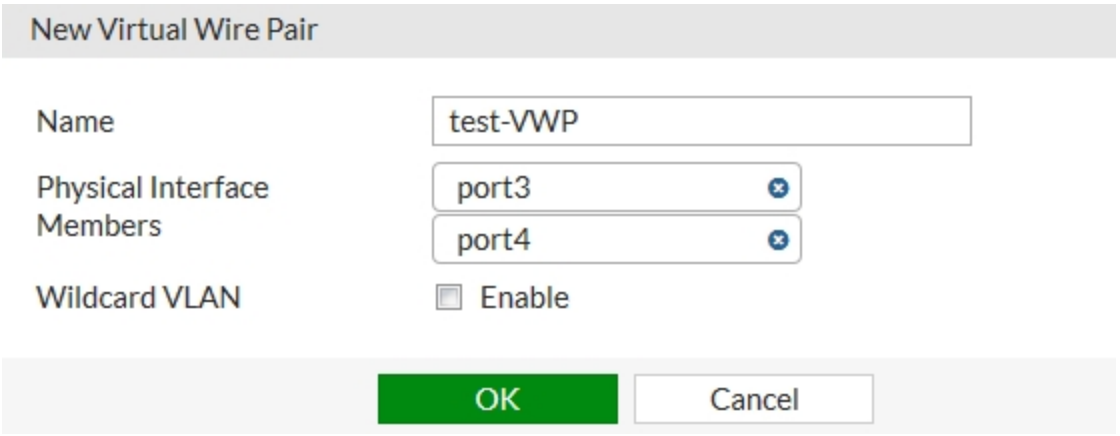
Virtual Wire Pair

This feature (276013), available in NAT and Transparent mode, replaces the Port Pair feature available in FortiOS 5.2 in Transparent mode only. When two physical interfaces are setup as a Virtual Wire Pair, they will have no IP addressing and are treated similar to a transparent mode VDOM. All packets accepted by one of the interfaces in a virtual wire pair can only exit the FortiGate through the other interface in the virtual wire pair and only if allowed by a virtual wire pair firewall policy. Packets arriving on other interfaces cannot be routed to the interfaces in a virtual wire pair. A FortiGate can have multiple virtual wire pairs.

You cannot add VLANs to virtual wire pairs. However, you can enable wildcard VLANs for a virtual wire pair. This means that all VLAN-tagged traffic can pass through the virtual wire pair if allowed by virtual wire pair firewall policies.

Adding a virtual wire pair

To add a virtual wire pair, go to **Network > Interfaces** and select **Create New > Virtual Wire Pair**. Select the interfaces to add to the virtual wire pair to, optionally enable Wildcard VLAN and select OK.



The virtual wire pair appears on the Interface list.

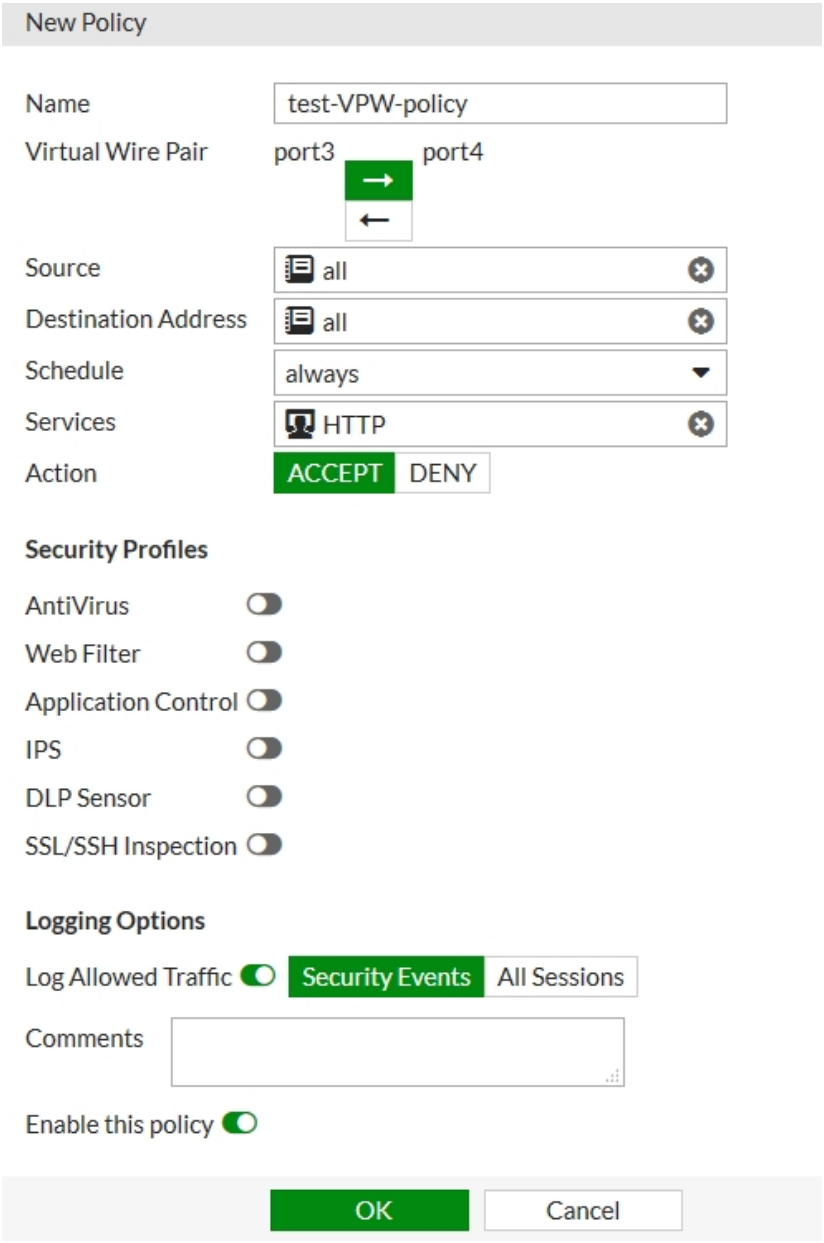
Use the following command to add a virtual wire pair from the CLI that enables the wildcard VLAN feature:

```
config system virtual-wire-pair
   edit test-VWP
      set member port3 port4
      set wildcard-vlan enable
   end
```

Assigning an interface to be part of a virtual wire pairing will remove the "role" value from the interface.

Adding a virtual wire pair firewall policy

You can add IPv4 and IPv6 virtual wire pair firewall policies. To add an IPv4 virtual wire pair firewall policy go to **Policy & Objects > IPv4 Virtual Wire Pair Policy**. Select the virtual wire pair that you want to add a policy for and select Create New. Start by configuring the direction of traffic though the policy and configure other policy settings like any firewall policy.



If you have a USB-wan interface, it will not be included in the interface list when building a wired pair.

WAN Link Load Balancing

In the same way that incoming traffic can be load balanced, outgoing or WAN traffic can also be load balanced and for the same three reasons.

1. Reduce the places in the work flow where a single point of failure can bring the process to a halt.
2. Expand the capacity of the resources to handle the required workload.
3. Have it configured so that the process of balancing the workload is automatic.

Often, it can be just as important for an organizations members to be able to access the Internet as it is for the denizens of the Internet to access the Web facing resources.

There is now a **WAN Load Balancing** feature located in the **Network** section of the GUI ("WAN LLB").

As part of the new WAN Load Balancing feature, the FortiOS 5.2 **Router > Static > Settings** GUI page has been removed. WAN Load Balancing should be used instead of the 5.2 **ECMP Load Balancing Method** settings. The 5.2 **Link Health Monitor** definitions are now only available from the CLI.

WAN links

The basis for the configuration of the virtual WAN link are the interfaces that comprise it. As interfaces are added to the "wan-load-balance" interface, they are added into the calculations that comprise the various algorithms used to do the load balancing.

- While most of the load balancing algorithms are based on equal distribution or weighted distribution, spill over does rely on which interface is first in the sequence, so this should be kept in mind when adding the interfaces.
- The interfaces in the virtual WAN link can be disabled if necessary if work needs to be done on an interface without interfering with the performance of the link.
- There is no requirement that the interfaces be those labeled on the hardware as WAN interfaces.
- In the GUI, to help analysis the effectiveness of the algorithm being used and its configuration, there is a graphic representation of the bandwidth usage of the link.

Load balancing algorithm

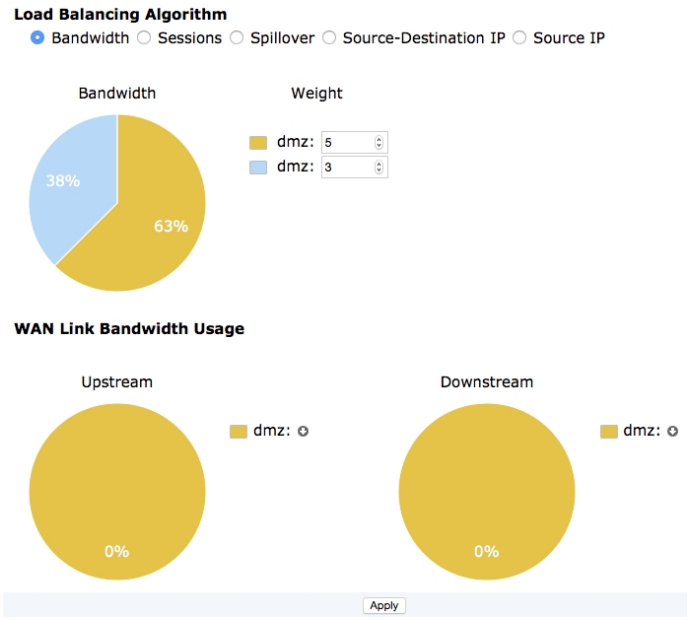
Once the interfaces involved has been configured the next step is to determine how the workload will be distributed. 5 load balancing algorithms are available to choose from.

Bandwidth

This is a very straight forward method of distributing the work load based on the amount of packets going through the interfaces. An integer value assigns a weight to each interface. These weights are used to calculate a percentage of the total bandwidth that is directed to the interface.

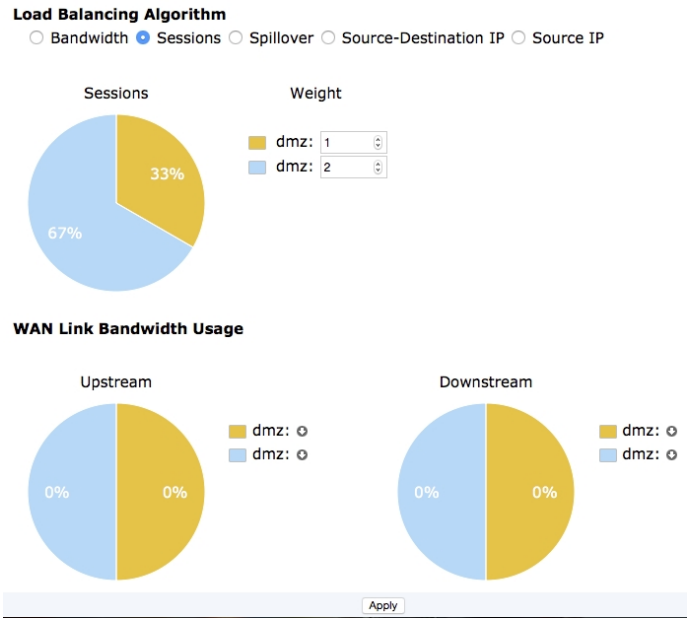
Example:

- There are 2 interfaces
- Interface #1 is assigned a weight of 5 because it is a 5 MB connection. (There is no requirement to match the weight to the capacity of the connection. It is just a simple way of optimizing the differing capacities in this case.)
- Interface #2 is assigned a weight of 3 because it is a 3 MB connection.
- The total weight is 8 so interface #1 gets 5/8 (63%) and interface #2 gets 3/8 (38%) of the traffic.



Sessions

The session algorithm is similar to the bandwidth algorithm in that it also uses an integer value to assign a weight to each interface. The difference is that the number of sessions connected is what is being measured and not the packets flowing through the interfaces.



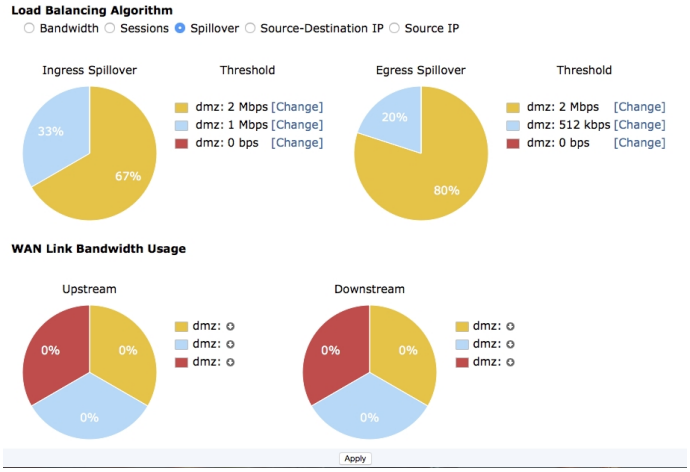
Spillover

Spillover is a method where a threshold is set for an interface (in kbps) and if the amount of traffic bandwidth exceeds the threshold any traffic bandwidth beyond that threshold is sent out through another interface.

It might be simple to just consider the outgoing or egress traffic when determining a threshold but two facts must be taken into consideration.

1. A simple request going out the interface can be responded to with significantly more data coming back from the other direction.
2. Internet connections come in a variety of configurations, many of which have different levels of allowed bandwidth capacity between the upload and download directions.

For these reasons, the FortiGate allows for the setting of both egress and ingress thresholds for bandwidth.



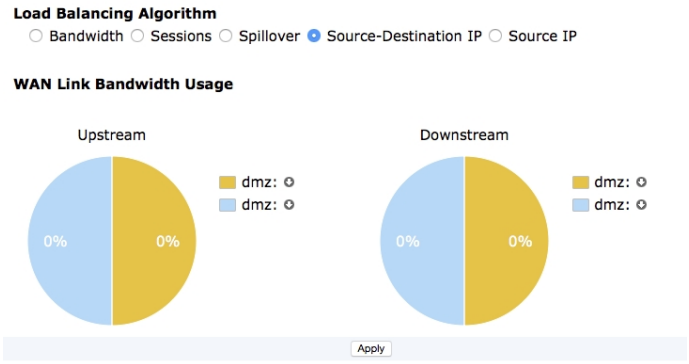
Source-destination IP

The source-destination IP algorithm tries to equally divide the traffic between the interfaces included in the virtual WAN interface. It used the connection criteria of the source and destination IP address combinations as a way of sorting the traffic.

Example:

- 10.10.10.10 to 1.1.1.2 gets sent out one interface
- Subsequent traffic going from 10.10.10.10 to 1.1.1.2 would also go out that same interface
- The next session to connect through the WAN could be either:
  - 10.10.10.27 going to 1.1.1.2
  - 10.10.10.10 going to 1.1.1.15.

Either one of the connections in the next session, even though they might match the source or the destination IP address do not match both. Traffic with the next unique combination of source and destination IP address would be sent out the other interface. It would go back and forth like this as new traffic and combinations comes in.



Source IP

The source IP address works just the same as the source-destination IP algorithm but it only concerns itself with the source IP address of the connection.

Avoid using WAN LLB in combination with asymmetric routing. Using the Bandwidth (GUI) or measure-based (CLI) load balancing algorithms can cause the routing-information (outgoing-interface) for sessions created in asymmetric routing to change in mid-session. Session-level persistence of the connection is needed to make WAN LLB effectively.

Priority rules

Some traffic requires that it come from a consistent or specific IP address to be processed properly. Because the different WAN interfaces will have different IP addresses there needs to be a way to override the unpredictability of the load balancing algorithms. This is done by using priority rules

Packets can be checked prior to being assigned an interface by the algorithm. If certain source and/or destination criteria matches the priority rules, the packets can be assigned to an outgoing interface as determined by the rule.

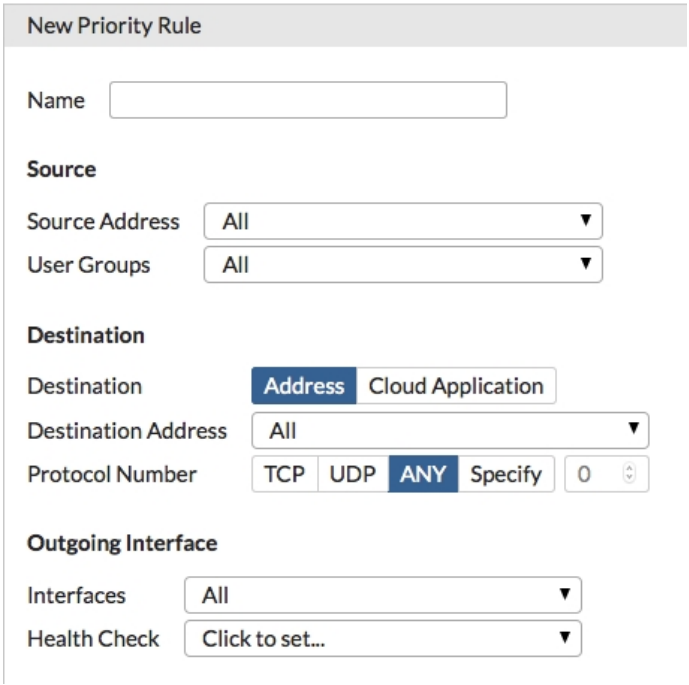
Priority rules can be configured under **Network > WAN LLB Rules**.

The source criteria that can be checked are:

- Source address
- User Group

The destination criteria that can be checked are:

- Whether it's address-based
  - Destination address
  - Protocol number
- Whether it's cloud application-based
  - The cloud application



Cloud applications

Cloud applications are a new object that can be used and configured on a FortiGate. There are a limited number of places that they can be used as a means of directing traffic and Virtual WAN links are one of them.

Estimated Bandwidth

An optional parameter has been added that allows users to set the estimated uplink and downlink bandwidths of a WAN interface.This setting is available in the GUI and the CLI. It's availability in the GUI is dependent on context. To see the setting when editing the interface, the role of the interface must be set to WAN.

The range of the setting is from 0 to 4294967295 (effectively 2^{32}). The value is in Kbps.

In the CLI, the fields can be set by using the following syntax:

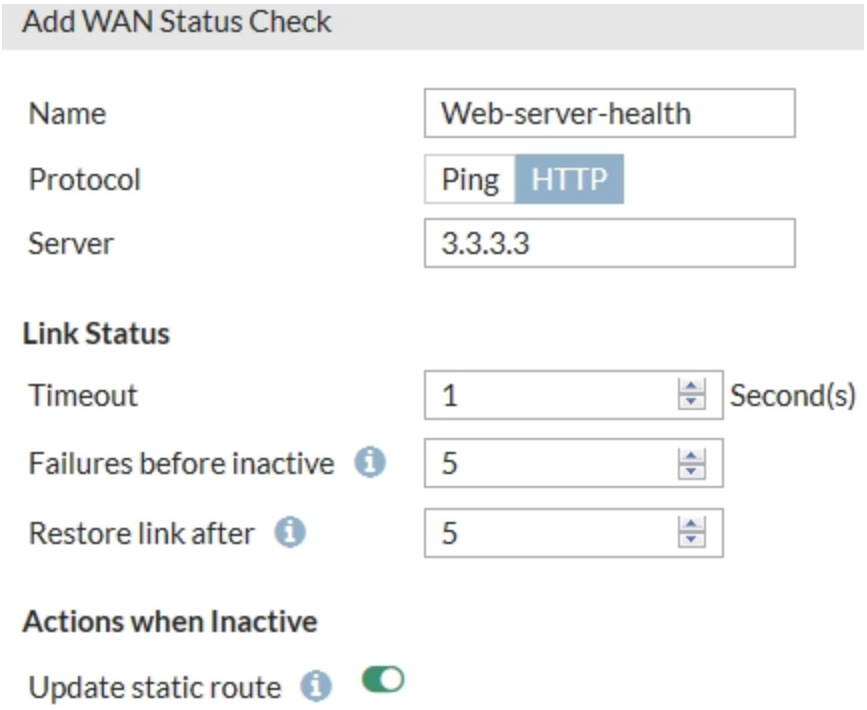
```
config system interface
   edit <wan interface>
      set estimated-upstream-bandwidth <integer from 0 - 4294967295>
      set estimated-downstream-bandwidth <integer from 0 - 4294967295>
      end
   end
```

The purpose for these settings is to work with monitoring software such as MRTG (Multi Router Traffic Grapher) to compare the estimated and real bandwith usage.This is not connected to threshold settings.

Status checking or health checking

For load balancing to be effective, there needs to be a constant monitoring of the health and status of the links that make up the virtual WAN link. Customized status checks can be configured to check on health of various aspects the traffic flow going through the link. Using either ICMP packets (PING) or HTTP requests to a designated server. Once the health reaches a specified threshold, the interface can be automatically removed from the virtual WAN link so that the algorithm is not sending traffic to a failed interface and bring down communications for a portion of the FortiGate's clientele.

To configure status or health checking go to Network > WAN Status Check and add status check profiles.



You can also configure status and health checking from the CLI. The CLI includes additional options for setting latency, jitter, and pack loss thresholds.

```
config system virtual-wan-link
   set fail-detect [enable | disable]
   set fail-alert-interfaces (available only if fail-detect is enabled)
   config health-check
      edit [Health check name]
         set server <string>
```

```
            set protocol [ping | tcp-echo | udp-echo | http | twamp]
```

Some of the protocol options cause additional settings are made available.

http

```
            set port
            set http-get
            set http-match
```

twamp

```
            set port
            set security-mode[none | authentication]
```

The `security-mode` setting authentication generates yet another potential setting, `password`.

```
            set password
            set packet-size
```

The next settings are available for all protocols

```
            set interval <integer>
            set timeout <integer>
            set failtime [1 - 10]
            set recoverytime [1 - 10]
            set update-cascade-interface [enable | disable]
            set update-static-route [enable | disable]
            set threshold-warning-latency <integer 0-4294967295>
            set threshold-alert-latency <integer 0-4294967295>
            set threshold-warning-jitter <integer 0-4294967295>
            set threshold-alert-jitter <integer 0-4294967295>
            set threshold-warning-packetloss <integer 0-4294967295>
            set threshold-alert-packetloss <integer 0-4294967295>
            end
         end
      end
```

Virtual-WAN-link improvements (365702)

Some new features have been incorporated into Virtual WAN Link to address the performance issues.

- The Virtual WAN link daemon only recalculates those services that have changed link quality.
- Removal of abnormal latency data.
- A link quality threshold has been added to prevent frequently route generation due to a small quality changes.
- Service ID field has been added
- A disable option is available for a service.
- Services in the CMDB are able to move and the order of policy routes in the kernel is based on the sequences of services in the CMDB.

Syntax for configuring a service ID

```
config system virtual-wan-link
   config service
      edit <service name>
           set id <integer between 0 - 255>
           end
```

Syntax for configuring the percentage threshold of change of link cost values that will result in a policy route generation

```
config system virtual-wan-link
   config service
      edit <service name>
           set link-cost-threshold <integer between 0 - 100000000>
           end
```

The default threshold is 10

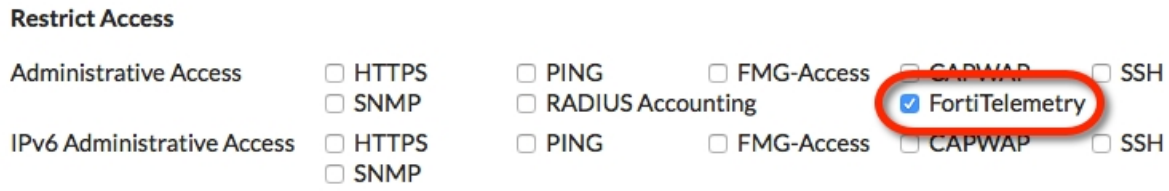
Syntax for enabling | disabling a service

```
config system virtual-wan-link
   config service
      edit <service name>
           set status [enable | disable]
           end
```

New features in 5.4.1

FortiTelemetry replaces FortiClient Access and other FortiClient interface settings (372945 299371)

To configure an interface to listen for connections from devices with FortiClient installed, enable **FortiTelemetryAdministrative Access**. FortiTelemetry was called FCT-Access or FortiClient Access in FortiOS 5.2.

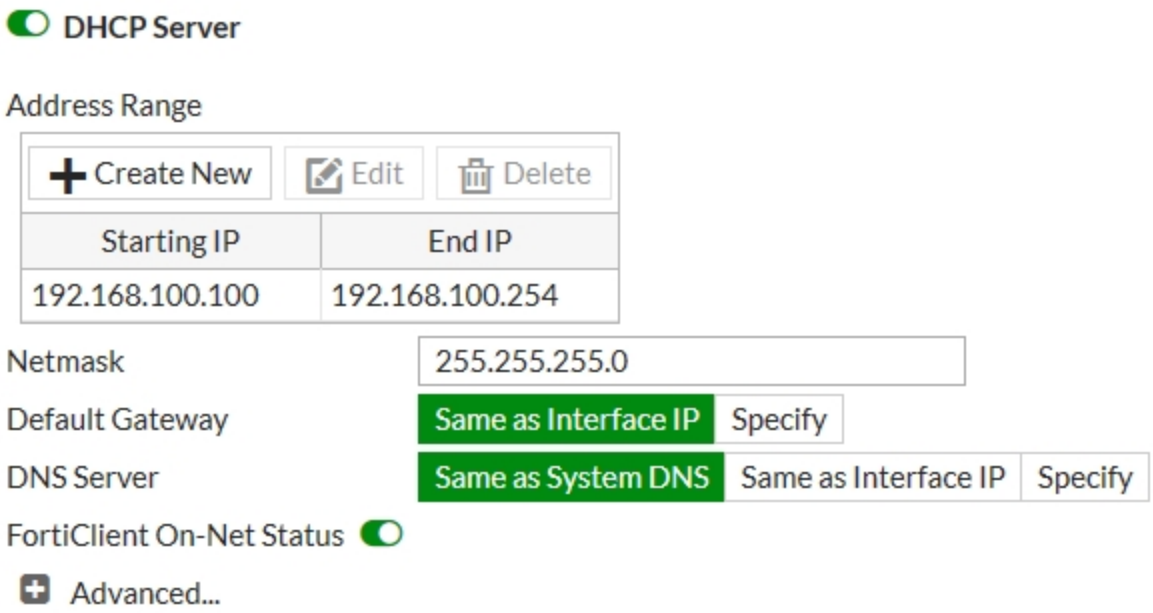


After enabling FortiTelemetry, under **Admission Control** you can select **Enforce FortiTelemetry for all FortiClients** to require clients to have FortiClient installed to be able to get access through the FortiGate. If you enable this feature you should also go to **Security Profiles > FortiClient Profiles** and configure FortiClient Profiles. Then you should add the configured FortiClient Profiles to firewall policies with device detection.

Use the following CLI command to enable FortiHeartBeat on an interface and enable enforcing FortiHeartBeat for all FortiClients:

```
config system interface
   edit port1
      set listen-forticlient-connection enable
      set endpoint-compliance enable
   end
```

After enabling FortiTelemetry, you can also enable **DHCP server** and turn on **FortiClient On-Net Status** to display the on-net status of FortiClient devices on the FortiClient Monitor (go to **Monitor > FortiClient Monitor**).



Use the following CLI command to enable FortiClient on-net status for a DHCP server added to the port1 interface:

```
config system dhcp server
   edit 1
      set interface port1
      set forticlient-on-net-status enable
   end
```

There was a name change involved with this feature. For 5.4.0, it was refered to as FortiHeartBeat, but this only appears in the 5.4.0 GA version of the FortiOS firmware.

TLS support for Dynamic DNS Services (DDNS) (300231)

This feature is available on the FortiGate 140-POE

When clear-text is disable, the FortiGate will use ssl connection to send and receive updates to Dynamic DNS services.

To disable clear-text:

```
config system ddns
   set clear-text disable
   end
```

The ssl-certificate name can also be set in the same location using the command:

```
   set ssl-certificate <cert_name>
```

Defaults:

- clear-text =`enable`
- ssl-certificate = `Fortinet_Factory`

DDNS update override for DHCP (306525 290048)

This feature is available on the FortiGate 140-POE

DHCP server now has an override command option, which allows DHCP server communications to go through DDNS to do updates for the DHCP client.

- This will force a DDNS update of the AA field every time even if the DHCP client does not request it.
- This will allow the support of the allow/ignore/deny client-updates options.

Syntax:

```
config system dhcp server
   edit 0
      set ddns-update_override [enable | disable]
      end
```

disable	Disable DDNS update override for DHCP
enable	Enable DDNS update override for DHCP

Enable or disable individual static and policy routes (174956)

CLI support has been added to [enable | disable] Static and Policy routes.

Syntax for static route in IPv4:

```
config route static
   edit 0
      set status [enable|disable]
      end
```

Syntax for static route in IPv6:

```
config route static6
   edit 0
      set status [enable|disable]
      end
```

Syntax for policy route in IPv4:

```
config router policy
   edit 0
      set status [enable|disable]
      end
```

Syntax for policy route in IPv6:

```
config router policy6
   edit 0
      set status [enable|disable]
```

```
end
```

New option to allow copying of DSCP value in GRE tunnels (306331)

DSCP stands for the Differentiated services code point found in IPv4 and IPv6 headers, used for classifying and managing network traffic such as it relates to Quality of Service. This feature enables the keeping of the DSCP marking in the packets after encapsulation for going through GRE tunnels.

New DHCPv6 Prefix hint feature (302304)

This feature is used to "hint" to upstream DCHPv6 servers a desired prefix length for their subnet to be assigned in response to its request.

There is a possibility of duplicate prefixes being sent by ISP when using a /64 bit subnet because the first 64 bits of the address are derived from the mac address of the interface. This could cause an issue if the system administrator wishes to divide the host networks into 2 /64 bit subnets.

By receiving a /60 bit (for example) network address, the administrator can then divide the internal host works without the danger of creating duplicate subnets.

Also included in the new feature are preferred times for the life and valid life of the DHCP lease.

DHCPv6 hint for the prefix length

`set dhcp6-prefix-hint` <DHCPv6 prefix that will be used as a hint to the upstream DHCPv6 server>

DHCPv6 hint for the preferred life time.

`set dhcp6-prefix-hint-plt` <integer> 1 ~ 4294967295 seconds or "0" for unlimited lease time

DHCPv6 hint for the valid life time.

`set dhcp6-prefix-hint-vlt` <integer> 1 ~ 4294967295 seconds or "0" for unlimited lease tim

The FortiOS DHCP server now has an increased number of DHCP option fields (307342)

In place of specific fields the DHCP server now maintains a table for the potential options. The FortiOS DHCP server supports upto a maximum of 30 custom options.These optional fields are set in the CLI.

To get to the DHCP server:

```
config system dhcp server
   edit <integer - ID of the specific DHCP server>
```

To configure the options:

```
config options
```

Once in the options context, a few new configuration commands are available. First create an ID for the table entry:

```
edit <integer>
   set code <integer between 0 - 4294967295 to determine the DHCP option>
   set type [ hex | string | ip ]
   set value <option content for DHCP option types hex and string>
   set ip <option content for DHCP option type ip>
end
```

New option to dedicate a FortiGate interface to connect to a managed FortiSwitch (294607)

When setting up an interface, an additional option has been added to the potential addressing modes that dedicates the interface to being the connection to a FortiSwitch.This is covered in more detail in the FortiSwitch section.

New CLI option to change the maximum number of IP route cache entries (363410)

The maximum number of route cache entries is configurable.

Syntax:

```
config system global
   set max-route-cache-size <integer between 0 - 2147483647>
   end
```

Unsetting the field will cause the value to be set to the kernel calculated default.

```
config system global
   unset max-route-cache-size
   end
```

Support for 802.1x fallback and 802.1x dynamic VLANs (308012)

There are 4 modes when enabling 802.1x on a virtual switch interface:

Default	In this mode, it works as it did previously.
Fallback	In fallback mode, the virtual switch will be treated as a master. Only one slave can refer to a fallback master. Those ports in the master virtual switch are always authorized. After passing 802.1x authentication, the ports will be stay authorized and moved to its slave virtual switch.
Dynamic-vlan	In dynamic-vlan mode, the virtual switch will also be treated as a master. However, many slaves can refer to a dynamic-vlan master. Those ports in the master virtual switch are always un-authorized. After passing 802.1x/MAB authentication, the ports will be set to authorized and moved to one of its slave virtual switches.
Slave	In slave mode, a master must be set through security-8021x-master attribute. A slave virtual switch will use its master virtual switch's security-groups settings for authentication.

CLI example for fallback mode

```
config system virtual-switch
   edit "fallsw"
      set physical-switch "sw0"
      config port
   end
   edit "trust"
      set physical-switch "sw0"
   end
config system interface
   edit "fallsw"
      set vdom "root"
      set ip 192.168.20.1 255.255.255.0
```

```
        set allowaccess ping https ssh snmp http telnet fgfm auto-ipsec radius-acct probe-
            response capwap
        set type hard-switch
        set security-mode 802.1X
        set security-8021x-mode fallback(fallback mode master switch)
        set security-groups "rds-grp"(the usergroup for 802.1x)
        set snmp-index 10
        next
    edit "trust"
        set vdom "root"
        set ip 192.168.22.1 255.255.255.0
        set allowaccess ping https ssh snmp http telnet fgfm auto-ipsec radius-acct probe-
            response
        set type hard-switch
        set security-mode 802.1X
        set security-8021x-mode slave(slave mode switch)
        set security-8021x-master "fallsw" (its master switch)
        set snmp-index 6
        next
    end
```

CLI example for dynamic-vlan mode

```
config system virtual-switch
    edit "internal"
        set physical-switch "sw0"
    edit "lan-trust"
        set physical-switch "sw0"
        next
    edit "lan-vlan1000"
        set physical-switch "sw0"
        next
    edit "lan-vlan2000"
        set physical-switch "sw0"
        config port
        edit "internal1" (normally we should not add port in slave switch. This is used if
            user wants to manually add one port in slave)
        end
    end
config system interface
    edit "internal"
        set vdom "root"
        set ip 192.168.11.99 255.255.255.0
        set allowaccess ping https ssh http fgfm capwap
        set type hard-switch
        set security-mode 802.1X
        set security-8021x-mode dynamic-vlan<------dynamic-vlan mode master switch
        set security-groups "rds-grp"<------the usergroup for 802.1x
        set snmp-index 15
        next
    edit "lan-trust"
        set vdom "root"
        set ip 192.168.111.99 255.255.255.0
        set allowaccess ping https ssh snmp http telnet fgfm auto-ipsec radius-acct probe-
            response capwap
        set type hard-switch
        set security-mode 802.1X
        set security-8021x-mode slave<-----slave mode switch
```

```
    set security-8021x-master "internal"<-----its master switch
    set snmp-index 7
    next
edit "lan-vlan1000"
    set vdom "root"
    set ip 192.168.110.1 255.255.255.0
    set allowaccess ping https ssh snmp http telnet fgfm auto-ipsec radius-acct probe-
        response capwap
    set type hard-switch
    set security-mode 802.1X
    set security-8021x-mode slave<-----slave mode switch
    set security-8021x-master "internal"<-----its master switch
    set security-8021x-dynamic-vlan-id 1000 <-----the matching vlan id for this virtual
        switch
    set snmp-index 16
    next
edit "lan-vlan2000"
    set vdom "root"
    set ip 192.168.220.1 255.255.255.0
    set allowaccess ping https ssh snmp http telnet fgfm auto-ipsec radius-acct probe-
        response capwap
    set type hard-switch
    set security-mode 802.1X
    set security-8021x-mode slave
    set security-8021x-master "internal"
    set security-8021x-dynamic-vlan-id 2000
    set snmp-index 17
    end
config user group
    edit "rds-grp"
       set dynamic-vlan-id 4000(default vlan id if there is no vlan attribute return
           from server)
       set member "190"
    end
```

New features in 5.4.0

Internet-Service database (288672 281333 291858)

Go to ***Policy & Objects > Internet Service Database*** to view the Internet Service Database. The database contains detailed information about services available on the Internet such as DNS servers provided by Adobe, Google, Fortinet, Apple and so on and a wide range of other services. For each service the database includes the IP addresses of the servers that host the service as well as the port and protocol number used by each IP address.

Interfaces assigned to Virtual Wired Pairs don't have "roles" (296519)

Assigning an interface to be part of a virtual wire pairing will remove the "role" value from the interface.

STP (Spanning Tree Protocol) support for models with hardware switches (214901 291953)

STP used to be only available on the old style switch mode for the internal ports. It is now possible to activate STP on the hardware switches found in the newer models. These models use a virtual switch to simulate the old

Switch Mode for the Internal ports.

The syntax for enabling STP is as follows:

```
config system interface
   edit lan
   set stp [enable | disable]
   end
```

Command to determine interface transceiver optical signal strength (205138 282307)

The new `get system interface transceiver` command can be used to determine optical signal strength when using SFP/SFP+ modules. The command can be used for trouble shooting fiber optic connections to service providers. This command is hardware dependent and currently supported by FortiGate models that include various SFP/SFP+ interfaces including the FortiGate-100D/200D-POE/400D/500D/900D/1000D/1200D/1500D/3700D/3700DX) models.

New command to get IPv6 multicast router information (267650)

The following command displays IPv6 multicast router information just like the IPv4 version of the command.

```
get router info6 multicast.
```

FortiGate DHCP works with DDNS to allow FQDN connectivity to leased IPs (267043)

As clients are assigned IP addresses, they send back information that would be found in an A record to the FortiGate's DHCP server, which can take this information and passes it back to a corporate DNS server so that even devices using leased IP address can be reached using FQDNs. The settings for this feature are configured through the CLI using the ddns-update command and some other ddns related options.

Fortinet's Dynamic DNS services (FortiDDNS) can be registered to a public IP address (251748)

Fortinet's Dynamic DNS services (FortiDDNS) can be registered to a public IP address even if the FortiGate itself does not have any physical interfaces on the Internet. This is applicable when the FortiGate is behind other networking devices that are employing NAT. This can be configured in the GUI as well as CLI.

Can use firewall addresses for static route destinations (273672)

To help prevent false positive when scanning for duplicate static routes, the dst_addr field is also checked.

Can use firewall addresses for policy route destinations (244101)

When configuring a policy route, firewall addresses and address groups can be used. The only exception for address types that can be used is the URL type of address object.

Enhance TWAMP Light functionality with server/controller functionality (249255)

TWAMP(Two-Way Active Measurement Protocol) Light is a simplified architecture within the TWAMP standard. Its purpose is to measure the round trip IP performance between any two devices within a network that supports the protocol. Now FortiOS operates in more than just the role of responder/reflector.The server/controller functionality has been added.

More information about interface status available from GUI (240285)

The following information is added to the 'hover' details for each port on the GUI FortiGate faceplate:

- MAC address
- Tx/Rx bytes
- Tx/Rx packets
- Tx/Rx errors

In addition, optional columns are added to the interface list to allow users to see all of the above information.

Virtual WAN link fixes (255122)

The firmware now has the following fixes or improvements to Virtual WAN links (VWL):

- Better support for dynamic interfaces (PPPoE and DHCP).
  - It can remove dynamically added routes, and restore these routes once the interfaces are not members.
  - It can count pppoe interface sessions.
  - It can generate a proute for a PPPoE interface. In this proute, the gateway is specified, while the outgoing (PPPoE)interface will not set.
- Adjust the route policy for a manual mode VWL service
- Support HTTP monitor by version 1.1, which obsoletes version 1.0's behavior.
- Apply multiple dst and src new feature for one policy to VWL.
- Improvements to CLI usability:
  - It hides interfaces that are being used in a policy or a zone
  - There is a check when adding an interface to a static route. This check will raise an error if the interface is a member of a VWL.
  - Updates a proute, if based on config change, if the associated link-monitor dies.
  - Fix some inappropriate messages.
  - Revised the minimum value of interval for a link-monitor object. The new value is 1, so it can be compatible with V5.0. When the timeout is 1, and interval is 1.

Router > Static > Settings GUI options available from the CLI only

As part of the new WAN Load Balancing feature, the FortiOS 5.2 **Router > Static > Settings** GUI page has been removed. WAN Load Balancing should be used instead of the 5.2 **ECMP Load Balancing Method** settings. The 5.2 **Link Health Monitor** definitions are now only available from the CLI.

Ports preassigned as sniffer ports by default (261921)

Some models of FortiGate, by default have ports preconfigured as sniffer ports.

The models and ports preconfigered in sniffer mode are as follows:

- FortiGate 300D
  - Port4
  - Port8
- FortiGate 500D
  - Port5
  - Port6
  - Port13
  - Port14

Enable or disable inspecting IPv4 and IPv6 ICMP traffic (258734)

In order for the inspection of assymetric ICMP traffic to not affect TCP and UDP traffic, a pair of settings have been added that can enable/disable the inspection of ICMP traffic being routed assymetricly for both IPv4 and IPv6.

The syntax in the CLI for configuring the setting is:

- IPv4

```
config system settings
   set asymroute-icmp
   end
```

- IPv6

```
config system settings
   set asymroute6-icmp
   end
```

Send GARP on aggregate MAC change (273363)

FortiGates will send out GARP (Gratuitous Address Resolution Protocol) announcements if the MAC address of a link aggregated interface has changed to a new IP pool address due to a link failure or change in ports. This is needed when using networking devices, such as some switches, that don't perform this function when they receive LACP (Link Aggregation Control Protocol) information about changes in the MAC information.

Support split ports (252444)

The 5001D 40 GB can be split into 4 10 GB ports.This is done through a combination of hardware and software configuration. A specific 40 GB connector is used to connect to the 40 GB port and normally, the other end of the fibre optic cable would connect to another 40 GB port but a special cable can be used that is a single 40 GB connector at one end and 4 10 GB connections at the other. To use this set up the port also has to be configured to be a split port.

The configuration option can be found in the CLI:

```
config system global
   set port-split port1 port2
   end
```

The ports will be checked to make sure that they are not in use or referenced by other policy configurations. If in use the command will be aborted. Changing the port to be a split port will require a system reboot.

Add FortiClient enforcement to interfaces (253933)

The use of FortiClient can be enforced on individual interfaces. Go to **Network > Interfaces** and pick the interface of your choice. Under the heading **Admission Control**, you can enable the setting **Allow FortiClient Connections**.Once this setting is enabled, two more options become visible, **Discover Clients (Broadcast)** and **FortiClient Enforcement**. By enabling FortiClient Enforcement you enforce that in order for incoming traffic to pass through that interface it must be initiated by a device running FortiClient.

Once the use of FortiClient is enforced on the interface, FortiClient profiles should also be configured for the incoming connections. You can also set up any exemptions that are needed. Just below the **FortiClient Enforcement** option are fields for **Exempt Sources** and **Exempt Destinations/Services**. These can be selected from address or services object already configured on the FortiGate.

In the CLI the enforcement can be set up as follows:

```
config system interface
   edit port1
      set listen-forticlient-connection [enable|disable]
      set endpoint-compliance [enable|disable]
      end
```

Botnet C&C protection added to interfaces (254959)

The function of Botnet and Command & Control traffic protection is not new but how it can be configured has changed. It is no longer part of the AntiVirus Security profile.

The option to **ScanOutgoing Connections to Botnet Sites** has been added to the Interface page in the GUI.

The options are **Disable**, **Block** and **Monitor.**

In the CLI, the botnet scan can be configured on the interface by entering the following commands:

```
config system interface
   edit <interface>
      set scan-botnet-connections [disable | block | monitor]
      end
```

It is also possible to enable the scanning of botnet and C&C traffic in

- Firewall policies

```
config firewall policy
   edit <policyid>
      set scan-botnet-connections [disable | block | monitor]
      end
```

- Firewall explicit proxy policies

```
config firewall explicit-proxy-policy
   edit <policyid>
      set scan-botnet-connections [disable | block | monitor]
      end
```

- Firewall interface policy

```
config firewall interface-policy
   edit <policyid>
      set scan-botnet-connections [disable | block | monitor]
      end
```

- Firewall sniffer

```
config firewall sniffer
   edit <policyid>
      set scan-botnet-connections [disable | block | monitor]
      end
```

Netflow 9.0 support (167405)

Netflow is a networking feature introduced by Cisco to collect and export information about traffic flow through routers. IPFIX (Internet Protocol Flow Information Export) is the standardized Internet Protocol based on NetFlow version 9. The standards requirements for IPFIX are outlined in RFC 3197 and its basic specifications and other information are documented in RFC 5103, RFC 6759 and RFC 7011 through RFC 7015.

The CLI changes that enable and configure "NetFlow" traffic are:

```
config system netflow
   set collector-ip <collector IP>
```

```
    set collector-port <NetFlow collector port>
    set csource-ip <Source IP for NetFlow agent>
    set cactive-flow-timeout <time in minutes of timeout to report active flows>
    set cinactive-flow-timeout <time in seconds of timeout for periodic report of finished
        flows>
    end
```

These setting can also be configured per VDOM by going to:

```
config system vdom-netflow
```

A Netflow sampler will also have to be enabled on specific interfaces.

IPv6 blackhole static routing (220101)

System administrators use black hole routing to divert undesirable traffic, such as packets from a Denial of Service (DoS) attack or communications from an illegal source. The traffic is routed to a dead interface, or a host designed to collect information for investigation. This mitigates the impact of the attack on the network.

The use of blackhole routing is enabled in the CLI as follows:

```
config router static6
   edit <ID #>
      set blackhole enable
   end
```

A collection of Routing changes (261043)

A few new settings have been added to the CLI to assist in the supporting of the IPsec Auto Discovery feature. They are designed for:

- The support of the RIPng (RIP next generation) network command
- Limiting the maximum metric allowed to output for RIPng
- Fix NSM missing kernel address update info

The actual new settings are:

```
config router rip
   set max-out-metric <integer value 1 - 15>
   end

config router ripng
   set max-out-metric <integer value 1 - 15>
   end

config router ripng
   config network
      edit <ID # of network>
         set prefix <IPv6 prefix>
         end
      end
```

DHCPv6 prefix delegation (266061)

Prefix delegation is now support for DHCP for IPv6 addressing. It is not practical to manually provision networks on a large scale in IPv6 networking. The DHCPv6 prefix delegation feature is used to assign a network address prefix, and automate the configuration and provisioning of the public routable addresses for the network.

Enabling the prefix delegation is done only in the CLI as in the following example:

```
config system interface
   edit "wan1"
      config ipv6
         set ip6-mode dhcp
         set ip6-allowaccess ping
         set dhcp6-prefix-delegation enable
         end
      end
```

Proxy-arp extensions (250651)

The proxy-arp configuration can be extendend to an IP address range rather than a single IP address. A new setting has been added to the CLI. When configuring the proxy-arp, in addtion to setting the IP address, an end-ip address can also be set. If it is not set, the proxy-arp will be a single address as before. An example configuration using the new setting would be a follows:

```
config system proxy-arp
   edit 1
      set interface "internal"
      set ip 192.168.1.100
      set end-ip 192.168.1.102
      end
```

Advanced Static Routing

Advanced static routing includes features and concepts that are used in more complex networks.

This section includes:

Routing concepts

Many routing concepts apply to static routing. However without first understanding these basic concepts, it is difficult to understand the more complex dynamic routing.

This section includes:

- Routing in VDOMs
- Default route
- Adding a static route
- Routing table
- Building the routing table
- Static routing security
- Multipath routing and determining the best route
- Route priority
- Troubleshooting static routing

Routing in VDOMs

Routing on FortiGate units is configured per-VDOM. This means if VDOMs are enabled, you must enter a VDOM to do any routing configuration. This allows each VDOM to operate independently, with its own default routes and

routing configuration.

In this guide, the procedures assume your FortiGate unit has VDOMs disabled. This is stated in the assumptions for the examples. If you have VDOMs enabled you will need to perform the following steps in addition to the procedure's steps.

To route in VDOMs - web-based manager

Select the VDOM that you want to view or configure at the bottom of the main menu.

To route in VDOMs - CLI

Before following any CLI routing procedures with VDOMs enabled, enter the following commands. For this example, it is assumed you will be working in the root VDOM. Change root to the name of your selected VDOM as needed.

```
config vdom
   edit root
```

Following these commands, you can enter any routing CLI commands as normal.

Default route

The default route is used if either there are no other routes in the routing table or if none of the other routes apply to a destination. Including the gateway in the default route gives all traffic a next-hop address to use when leaving the local network. The gateway address is normally another router on the edge of the local network.

All routers, including FortiGate units, are shipped with default routes in place. This allows customers to set up and become operational more quickly. Beginner administrators can use the default route settings until a more advanced configuration is warranted.

Adding a static route

To add or edit a static route, go to **Network > Static Routes** and select **Create New**.

Destination IP / Mask	Enter the destination IP address and netmask. A value of `0.0.0.0/0.0.0.0` is universal.
Device	Select the name of the interface which the static route will connect through.
Gateway	Enter the gateway IP address.
Distance	Enter the distance value, which will affect which routes are selected first by different protocols for route management or load balancing. The default is 10.
Priority	Enter the priority if desired, which will artificially weight the route during route selection. The higher the number, the less likely the route is to be selected over others. The default is 0.

Routing table

When two computers are directly connected, there is no need for routing because each computer knows exactly where to find the other computer. They communicate directly.

Networking computers allows many computers to communicate with each other. This requires each computer to have an IP address to identify its location to the other computers. This is much like a mailing address - you will not receive your postal mail at home if you do not have an address for people to send mail to. The routing table on a computer is much like an address book used to mail letters to people in that the routing table maintains a list of how to reach computers. Routing tables may also include information about the quality of service (QoS) of the route, and the interface associated with the route if the device has multiple interfaces.

Looking at routing as delivering letters is more simple than reality. In reality, routers loose power or have bad cabling, network equipment is moved without warning, and other such events happen that prevent static routes from reaching their destinations. When any changes such as these happen along a static route, traffic can no longer reach the destination — the route goes down. Dynamic routing can address these changes to ensure traffic still reaches its destination. The process of realizing there is a problem, backtracking and finding a route that is operational is called convergence. If there is fast convergence in a network, users won't even know that re-routing is taking place.

The routing table for any device on the network has a limited size. For this reason, routes that aren't used are replaced by new routes. This method ensures the routing table is always populated with the most current and most used routes—the routes that have the best chance of being reused. Another method used to maintain the routing table's size is if a route in the table and a new route are to the same destination, one of the routes is selected as the best route to that destination and the other route is discarded.

Routing tables are also used in unicast reverse path forwarding (uRPF). In uRPF, the router not only looks up the destination information, but also the source information to ensure that it exists. If there is no source to be found, then that packet is dropped because the router assumes it to be an error or an attack on the network.

The routing table is used to store routes that are learned. The routing table for any device on the network has a limited size. For this reason, routes that aren't used are replaced by new routes. This method ensures the routing table is always populated with the most current and most used routes — the routes that have the best chance of being reused. Another method used to maintain the routing table's size is if a route in the table and a new route are to the same destination, one of the routes is selected as the best route to that destination and the other route is discarded.

Some actions you can perform on the routing table include:

- Viewing the routing table in the web-based manager
- Viewing the routing table in the CLI
- Searching the routing table

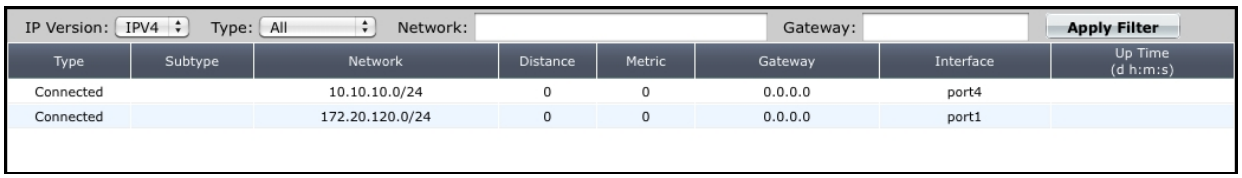
Viewing the routing table in the web-based manager

By default, all routes are displayed in the Routing Monitor list. The default static route is defined as 0.0.0.0/0, which matches the destination IP address of "any/all" packets.

To display the routes in the routing table, go to **Monitor > Routing Monitor**.

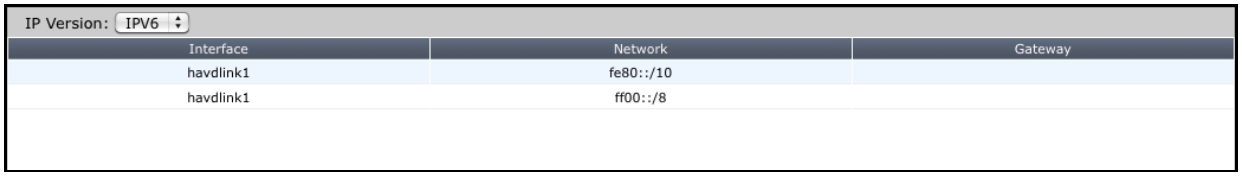
The figure below shows the Routing Monitor list belonging to a FortiGate unit that has interfaces named "port1" and "port4". The names of the interfaces on your FortiGate unit may be different.

Routing Monitor list - IPv4



The following figure shows the Routing Monitor list when IPv6 has been selected. Note that the information available for IPv6 is limited.

Routing Monitor list - IPv6



IP Version	Select IPv4 or IPv6. This is available only when IPv6 is enabled in the web-based manager. The fields displayed in the table depend on which IP version is selected.

Type	The type values assigned to FortiGate unit routes (Static, Connected, RIP, OSPF, or BGP). **All** — all routes recorded in the routing table. **Connected** — all routes associated with direct connections to FortiGate unit interfaces. **Static** — the static routes that have been added to the routing table manually. **RIP** — all routes learned through RIP. For more information see Routing Information Protocol (RIP) on page 2387. **RIPNG** — all routes learned through RIP version 6 (which enables the sharing of routes through IPv6 networks). **BGP** — all routes learned through BGP. For more information see Border Gateway Protocol (BGP) on page 2465. **OSPF** — all routes learned through OSPF. For more information see Open Shortest Path First (OSPF) on page 2424. **OSPF6** — all routes learned through OSPF version 6 (which enables the sharing of routes through IPv6 networks). **IS-IS** — all routes learned through IS-IS. For more information see Intermediate System to Intermediate System Protocol(IS-IS) on page 2502. **HA** — RIP, OSPF, and BGP routes synchronized between the primary unit and the subordinate units of a high availability (HA) cluster. HA routes are maintained on subordinate units and are visible only if you are viewing the router monitor from a virtual domain that is configured as a subordinate virtual domain in a virtual cluster. Not displayed when IPv6 is selected. For details about HA routing synchronization, see the FortiGate HA User Guide.

Subtype	If applicable, the subtype classification assigned to OSPF routes. An empty string implies an intra-area route. The destination is in an area to which the FortiGate unit is connected. **OSPF inter area** — the destination is in the OSPF AS, but the FortiGate unit is not connected to that area. **External 1** — the destination is outside the OSPF AS. This is known as OSPF E1 type. The metric of a redistributed route is calculated by adding the external cost and the OSPF cost together. **External 2** — the destination is outside the OSPF AS. This is known as OSPF E2 type. In this case, the metric of the redistributed route is equivalent to the external cost only, expressed as an OSPF cost. **OSPF NSSA 1** — same as External 1, but the route was received through a not-so-stubby area (NSSA). **OSPF NSSA 2** — same as External 2, but the route was received through a not-so-stubby area. For more information on OSPF subtypes, see Open Shortest Path First (OSPF) on page 2424. Not displayed when IP version 6 is selected.
Network	The IP addresses and network masks of destination networks that the FortiGate unit can reach.
Gateway	The IP addresses of gateways to the destination networks.
Interface	The interface through which packets are forwarded to the gateway of the destination network.
Up Time	The total accumulated amount of time that a route learned through RIP, OSPF, or BGP has been reachable. Not displayed when IP version IPv6 is selected.
Distance	The administrative distance associated with the route. A value of 0 means the route is preferable compared to other routes to the same destination, and the FortiGate unit may routinely use the route to communicate with neighboring routers and access servers. Modifying this distance for dynamic routes is route distribution. See Border Gateway Protocol (BGP) on page 2465. Not displayed when IP version 6 is selected.

Metric	The metric associated with the route type. The metric of a route influences how the FortiGate unit dynamically adds it to the routing table. The following are types of metrics and the protocols they are applied to. **Hop count** — routes learned through RIP. **Relative cost** — routes learned through OSPF. **Multi-Exit Discriminator (MED)** — routes learned through BGP. However, several attributes in addition to MED determine the best path to a destination network. For more information on BGP attributes, see Border Gateway Protocol (BGP) on page 2465. By default, the MED value associated with a BGP route is zero. However, the MED value can be modified dynamically. If the value was changed from the default, the Metric column will display a non-zero value. Not displayed when IP version 6 is selected.

Viewing the routing table in the CLI

In the CLI, you can easily view the static routing table just as in the web-based manager or you can view the full routing table.

When viewing the list of static routes using the CLI command `get router static`, it is the configured static routes that are displayed. When viewing the routing table using the CLI command `get router info routing-table all`, it is the entire routing table information that is displayed including configured and learned routes of all types. The two are different information in different formats.

If VDOMs are enabled on your FortiGate unit, all routing related CLI commands must be performed within a VDOM and not in the global context.

To view the routing table

```
# get router info routing-table all
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
O  - OSPF, IA - OSPF inter area
N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
E1 - OSPF external type 1, E2 - OSPF external type 2
i  - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
*  - candidate default

S*  0.0.0.0/0 [10/0] via 192.168.183.254, port2
S    1.0.0.0/8 [10/0] via 192.168.183.254, port2
S   2.0.0.0/8 [10/0] via 192.168.183.254, port2
C   10.142.0.0/23 is directly connected, port3
B   10.160.0.0/23 [20/0] via 10.142.0.74, port3, 2d18h02m
C 192.168.182.0/23 is directly connected, port2
```

Examining an entry:

```
B 10.160.0.0/23 [20/0] via 10.142.0.74, port3, 2d18h02m
```

B	BGP. The routing protocol used.
10.160.0.0/23	The destination of this route including netmask.
[20/0]	20 indicates and administrative distance of 20 out of a range of 0 to 255. 0 is an additional metric associated with this route, such as in OSPF
10.142.0.74	The gateway, or next hop.
port3	The interface used by this route.
2d18h02m	How old this route is, in this case almost three days old.

To view the kernel routing table

```
# get router info kernel

tab=254 vf=0 scope=253 type=1 proto=2 prio=0 0.0.0.0/0.0.0.0/0->10.11.201.0/24
    pref=10.11.201.4 gwy=0.0.0.0 dev=5(external1)

tab=254 vf=0 scope=253 type=1 proto=2 prio=0 0.0.0.0/0.0.0.0/0->172.20.120.0/24
    pref=172.20.120.146 gwy=0.0.0.0 dev=6(internal)
```

The parts of the routing table entry are:

tab	Table number. This will be either 254 (unicast) or 255 (multicast).
vf	Virtual domain of the firewall. This is the vdom index number. If vdoms are not enabled, this number will be 0.
type	Type of routing connection. Valid values include: 0 - unspecific 1 - unicast 2 - local 3 - broadcast 4 - anycast 5 - multicast 6 - blackhole 7 - unreachable 8 - prohibited

proto	Type of installation. This indicates where the route came from. Valid values include: 0 - unspecific 2 - kernel 11 - ZebOS routing module 14 - FortiOS 15 - HA 16 - authentication based 17 - HA1
prio	Priority of the route. Lower priorities are preferred.
->10.11.201.0/24 **(->x.x.x.x/mask)**	The IP address and subnet mask of the destination
pref	Preferred next hop along this route
gwy	Gateway - the address of the gateway this route will use
dev	Outgoing interface index. This number is associated with the interface for this route, and if VDOMs are enabled the VDOM will be included here as well. If an interface alias is set for this interface it will also be displayed here.

Searching the routing table

You can apply a filter to search the routing table and display certain routes only. For example, you can display one or more static routes, connected routes, routes learned through RIP, OSPF, or BGP, and routes associated with the network or gateway that you specify.

If you want to search the routing table by route type and further limit the display according to network or gateway, all of the values that you specify as search criteria must match corresponding values in the same routing table entry in order for that entry to be displayed — an implicit AND condition is applied to all of the search parameters you specify.

For example, if the FortiGate unit is connected to network 172.16.14.0/24 and you want to display all directly connected routes to network 172.16.14.0/24, you must select **Connected** from the **Type** list, type `172.16.14.0/24` in the **Network** field, and then select **Apply Filter** to display the associated routing table entry or entries. Any entry that contains the word “Connected” in its **Type** field and the specified value in the **Gateway** field will be displayed.

In this example, you will apply a filter to search for an entry for static route to 10.10.10.10/24

To search the FortiGate unit routing table in the web-based manager

1. Go to **Monitor > Routing Monitor**.
2. From the **Type** list, select the type of route to display. In our example, select **Static**.
3. If you want to display routes to a specific network, type the IP address and netmask of the network in the Networks field. In our example, enter `10.10.10.10/24`.

4. If you want to display routes to a specific gateway, type the IP address of the gateway in the **Gateway** field.
5. Select **Apply Filter**.

All of the values that you specify as search criteria must match corresponding values in the same routing table entry in order for that entry to be displayed.

To search the FortiGate unit routing table in the CLI

```
FGT # get router info routing-table details 10.10.10.10
Routing entry for 10.10.10.10/24
   Known via "static", distance 10, metric 0, best
```

If there are multiple routes that match your filter, they will all be listed, with the best match at the top of the list as indicated by the word best.

Building the routing table

In the factory default configuration, the FortiGate unit routing table contains a single static default route. You can add routing information to the routing table by defining additional static routes.

It is possible that the routing table is faced with several different routes to the same destination—the IP addresses of the next-hop router specified in those routes or the FortiGate interfaces associated with those routes may vary. In this situation, the “best” route is selected from the table.

The FortiGate unit selects the “best” route for a packet by evaluating the information in the routing table. The “best” route to a destination is typically associated with the shortest distance between the FortiGate unit and the closest gateway, also known as a next-hop router. In some cases, the next best route may be selected if the best route is unavailable.

The FortiGate unit installs the best available routes in the unit’s forwarding table, which is a subset of the unit’s routing table. Packets are forwarded according to the information in the forwarding table.

Static routing security

Securing the information on your company network is a top priority for network administrators. Security is also required as the routing protocols used are internationally known standards that typically provide little or no inherent security by themselves.

The two reasons for securing your network are the sensitive and proprietary information on your network, and also your external bandwidth. Hackers not only can steal your information, but they can also steal your bandwidth. Routing is a good low level way to secure your network, even before UTM features are applied.

Routing provides security to your network in a number of ways including obscuring internal network addresses with NAT and blackhole routing, using RPF to validate traffic sources, and maintaining an access control list (ACL) to limit access to the network.

This section includes:

- Network Address Translation (NAT)
- Access Control List (ACL)
- Blackhole Route
- Reverse path lookup

Network Address Translation (NAT)

Network address translation (NAT) is a method of changing the address from which traffic appears to originate. This practice is used to hide the IP address on a company's internal networks, and helps prevent malicious attacks that use those specific addresses.

This is accomplished by the router connected to that local network changing all the IP addresses to its externally connected IP address before sending the traffic out to the other networks, such as the Internet. Incoming traffic uses the established sessions to determine which traffic goes to which internal IP address. This also has the benefit of requiring only the router to be very secure against external attacks, instead of the whole internal network as would be the case without NAT. Securing the network is much cheaper and easier to maintain.

1. Configuring NAT on your FortiGate unit includes the following steps.
2. Configure your internal network. For example use the `10.11.101.0` subnet.
3. Connect your internal subnet to an interface on your FortiGate unit. For example use `port1`.
4. Connect your external connection, for example an ISP gateway of `172.20.120.2`, to another interface on your Fortigate unit, for example `port2`.

Configure security policies to allow traffic between port1 and port2 on your FortiGate unit, ensuring that the NAT feature is enabled.

The above steps show that traffic from your internal network will originate on the 10.11.101.0 subnet and pass on to the 172.20.120.0 network. The FortiGate unit moves the traffic to the proper subnet. In doing that, the traffic appears to originate from the FortiGate unit interface on that subnet — it does not appear to originate from where it actually came from.

NAT "hides" the internal network from the external network. This provides security through obscurity. If a hacker tries to directly access your network, they will find the Fortigate unit, but will not know about your internal network. The hacker would have to get past the security-hardened FortiGate unit to gain access to your internal network. NAT will not prevent hacking attempts that piggy back on valid connections between the internal network and the outside world. However other UTM security measures can deal with these attempts.

Another security aspect of NAT is that many programs and services have problems with NAT. Consider if someone on the Internet tries to initiate a chat with someone on the internal network. The outsider only can access the FortiGate unit's external interface unless the security policy allows the traffic through to the internal network. If allowed in, the proper internal user would respond to the chat. However if its not allowed, the request to chat will be refused or time-out. This is accomplished in the security policy by allowing or denying different protocols.

Access Control List (ACL)

An access control list (ACL) is a table of addresses that have permission to send and receive data over a router's interface or interfaces. The router maintains an ACL, and when traffic comes in on a particular interface it is buffered, while the router looks up in the ACL if that traffic is allowed over that port or not. If it is allowed on that incoming interface, then the next step is to check the ACL for the destination interface. If the traffic passes that check as well the buffered traffic is delivered to its accentuation. If either of those steps fail the ACL check, the traffic is dropped and an error message may be sent to the sender. The ACL ensures that traffic follows expected paths, and any unexpected traffic is not delivered. This stops many network attacks. However, to be effective the ACL must be kept up to date —when employees or computers are removed from the internal network their IP addresses must also be removed from the ACL. For more information on the ACL, see the router chapter of the FortiGate CLI Reference.

Blackhole Route

A blackhole route is a route that drops all traffic sent to it. It is very much like /dev/null in Linux programming.

Blackhole routes are used to dispose of packets instead of responding to suspicious inquiries. This provides added security since the originator will not discover any information from the target network.

Blackhole routes can also limit traffic on a subnet. If some subnet addresses are not in use, traffic to those addresses (traffic which may be valid or malicious) can be directed to a blackhole for added security and to reduce traffic on the subnet.

The loopback interface, a virtual interface that does not forward traffic, was added to enable easier configuration of blackhole routing. Similar to a normal interface, this loopback interface has fewer parameters to configure, and all traffic sent to it stops there. Since it cannot have hardware connection or link status problems, it is always available, making it useful for other dynamic routing roles. Once configured, you can use a loopback interface in security policies, routing, and other places that refer to interfaces. You configure this feature only from the CLI. For more information, see the system chapter of the FortiGate CLI Reference.

Reverse path lookup

Whenever a packet arrives at one of the FortiGate unit's interfaces, the unit determines whether the packet was received on a legitimate interface by doing a reverse lookup using the source IP address in the packet header. This is also called anti-spoofing. If the FortiGate unit cannot communicate with the computer at the source IP address through the interface on which the packet was received, the FortiGate unit drops the packet as it is likely a hacking attempt.

If the destination address can be matched to a local address (and the local configuration permits delivery), the FortiGate unit delivers the packet to the local network. If the packet is destined for another network, the Fortigate unit forwards the packet to a next-hop router according to a policy route and the information stored in the FortiGate forwarding table.

Multipath routing and determining the best route

Multipath routing occurs when more than one entry to the same destination is present in the routing table. When multipath routing happens, the FortiGate unit may have several possible destinations for an incoming packet, forcing the FortiGate unit to decide which next-hop is the best one.

It should be noted that some IP addresses will be rejected by routing protocols. These are called Martian addresses. They are typically IP addresses that are invalid and not routable because they have been assigned an address by a misconfigured system, or are spoofed addresses.

Two methods to manually resolve multiple routes to the same destination are to lower the administrative distance of one route or to set the priority of both routes. For the FortiGate unit to select a primary (preferred) route, manually lower the administrative distance associated with one of the possible routes. Setting the priority on the routes is a FortiGate unit feature and may not be supported by non-Fortinet routers.

Administrative distance is based on the expected reliability of a given route. It is determined through a combination of the number of hops from the source and the protocol used. A hop is when traffic moves from one router to the next. More hops from the source means more possible points of failure. The administrative distance can be from 1 to 255, with lower numbers being preferred. A distance of 255 is seen as infinite and will not be installed in the routing table.

Here is an example to illustrate how administration distance works — if there are two possible routes traffic can take between two destinations with administration distances of 5 (always up) and 31 (sometimes not available),

the traffic will use the route with an administrative distance of 5. If for some reasons the preferred route (admin distance of 5) is not available, the other route will be used as a backup.

Different routing protocols have different default administrative distances. These different administrative distances are based on a number of factors of each protocol such as reliability, speed, and so on. The default administrative distances for any of these routing protocols are configurable.

Default administrative distances for routing protocols and connections

Routing protocol	Default administrative distance
Direct physical connection	1
Static	10
EBGP	20
OSPF	110
IS-IS	115
RIP	120
IBGP	200

Another method to determine the best route is to manually change the priority of both routes in question. If the next-hop administrative distances of two routes on the FortiGate unit are equal, it may not be clear which route the packet will take. Manually configuring the priority for each of those routes will make it clear which next-hop will be used in the case of a tie. The priority for a route be set in the CLI, or when editing a specific static route, as described in the next section. Lower priority routes are preferred. Priority is a Fortinet value that may or may not be present in other brands of routers.

All entries in the routing table are associated with an administrative distance. If the routing table contains several entries that point to the same destination (the entries may have different gateways or interface associations), the FortiGate unit compares the administrative distances of those entries first, selects the entries having the lowest distances, and installs them as routes in the FortiGate unit forwarding table. As a result, the FortiGate unit forwarding table contains only those routes having the lowest distances to every possible destination. While only static routing uses administrative distance as its routing metric, other routing protocols such as RIP can use metrics that are similar to administrative distance.

Route priority

After the FortiGate unit selects static routes for the forwarding table based on their administrative distances, the priority field of those routes determines routing preference. Priority is a Fortinet value that may or may not be present in other brands of routers.

You can configure the priority field through the CLI or the web-based manager. Priority values can range from 0 to 4 294 967 295. The route with the lowest value in the priority field is considered the best route. It is also the primary route.

To change the priority of a route - web-based manager

1. Go to **Network > Static Routes**.
2. Select the route entry, and select **Edit**.
3. Select **Advanced Options**.
4. Enter the **Priority** value.
5. Select **OK**.

To change the priority of a route - CLI

The following command changes the priority to 5 for a route to the address `10.10.10.1` on the `port1` interface.

```
config router static
   edit 1
      set device port1
      set gateway 10.10.10.10
      set dst 10.10.10.1
      set priority 5
   end
```

If there are other routes set to priority 10, the route set to priority 5 will be preferred. If there are routes set to priorities less than 5, those other routes will be preferred instead.

In summary, because you can use the CLI to specify which sequence numbers or priority field settings to use when defining static routes, you can prioritize routes to the same destination according to their priority field settings. For a static route to be the preferred route, you must create the route using the `config router static` CLI command and specify a low priority for the route. If two routes have the same administrative distance and the same priority, then they are equal cost multipath (ECMP) routes.

Since this means there is more than one route to the same destination, it can be confusing which route or routes to install and use. However, if you have enabled load balancing with ECMP routes, then different sessions will resolve this problem by using different routes to the same address.

Troubleshooting static routing

When there are problems with your network that you believe to be static routing related, there are a few basic tools available to locate the problem.

These tools include:

- Ping
- Traceroute
- Examine routing table contents

Ping

Beyond the basic connectivity information, ping can tell you the amount of packet loss (if any), how long it takes the packet to make the round trip, and the variation in that time from packet to packet.

If there is no packet loss detected, your basic network connectivity is OK.

If there is some packet loss detected, you should investigate:

- Possible ECMP, split horizon, network loops
- Cabling to ensure no loose connections

If there is total packet loss, you should investigate:

- Hardware - ensure cabling is correct, and all equipment between the two locations is accounted for
- Addresses and routes - ensure all IP addresses and routing information along the route is configured as expected
- Firewalls - ensure all firewalls are set to allow PING to pass through

To ping from a Windows PC

1. Go to a DOS prompt. Typically you go to **Start > Run**, enter `cmd` and select **OK**.
2. Enter `ping 10.11.101.100` to ping the default internal interface of the FortiGate unit with four packets.

To ping from an Apple computer

1. Open the Terminal.
2. Enter `ping 10.11.101.100`.
3. If the ping fails, it will stop after a set number of attempts. If it succeeds, it will continue to ping repeatedly. Press `Control+C` to end the attempt and see gathered data.

To ping from a Linux PC

1. Go to a command line prompt.
2. Enter "`/bin/etc/ping 10.11.101.101`".

Traceroute

Where ping will only tell you if it reached its destination and came back successfully, traceroute will show each step of its journey to its destination and how long each step takes. If ping finds an outage between two points, traceroute can be used to locate exactly where the problem is.

To use traceroute on an Windows PC

1. Go to a DOS prompt. Typically you go to **Start > Run**, enter "`cmd`" and select **OK**.
2. Enter "`tracert fortinet.com`" to trace the route from the PC to the Fortinet website.

To use traceroute from an Apple computer

1. Open the Terminal.
2. Enter `traceroute fortinet.com`.
3. The terminal will list the number of steps made. Upon reaching the destination, it will list three asterisks per line. Press `Control+C` to end the attempt.

To use traceroute on a Linux PC

1. Go to a command line prompt.
2. Enter "`/bin/etc/traceroute fortinet.com`".
   The Linux traceroute output is very similar to the MS Windows traceroute output.

Examine routing table contents

The first place to look for information is the routing table.

The routing table is where all the currently used routes are stored for both static and dynamic protocols. If a route is in the routing table, it saves the time and resources of a lookup. If a route isn't used for a while and a new route needs to be added, the oldest least used route is bumped if the routing table is full. This ensures the most recently used routes stay in the table. Note that if your FortiGate unit is in Transparent mode, you are unable to perform this step.

If the FortiGate is running in NAT mode, verify that all desired routes are in the routing table: local subnets, default routes, specific static routes, and dynamic routing protocols.

To check the routing table in the web-based manager, use the Routing Monitor — go to **Monitor > Routing Monitor**. In the CLI, use the command `get router info routing-table all`.

Static routing tips

When your network goes beyond basic static routing, here are some tips to help you plan and manage your static routing.

Always configure a default route

The first thing configured on a router on your network should be the default route. And where possible the default routes should point to either one or very few gateways. This makes it easier to locate and correct problems in the network. By comparison, if one router uses a second router as its gateway which uses a fourth for its gateway and so on, one failure in that chain will appear as an outage for all the devices downstream. By using one or very few addresses as gateways, if there is an outage on the network it will either be very localized or network-wide — either is easy to troubleshoot.

Have an updated network plan

A network plan lists different subnets, user groups, and different servers. Essentially is puts all your resources on the network, and shows how the parts of your network are connected. Keeping your plan updated will also help you troubleshoot problems more quickly when they arise.

A network plan helps your static routing by eliminating potential bottlenecks, and helping troubleshoot any routing problems that come up. Also you can use it to plan for the future and act on any changes to your needs or resources more quickly.

Plan for expansion

No network remains the same size. At some time, all networks grow. If you take future growth into account, there will be less disruption to your existing network when that growth happens. For example allocating a block of addresses for servers can easily prevent having to re-assign IP addresses to multiple servers due to a new server.

With static routing, if you group parts of your network properly you can easily use network masks to address each part of your network separately. This will reduce the amount of administration required both to maintain the routing, and to troubleshoot any problems.

Configure as much security as possible

Securing your network through static routing methods is a good low level method to defend both your important information and your network bandwidth.

- Implement NAT to obscure your IP address is an excellent first step.
- Implement black hole routing to hide which IP addresses are in use or not on your local network.
- Configure and use access control list (ACL) to help ensure you know only valid users are using the network.

All three features limit access to the people who should be using your network, and obscure your network information from the outside world and potential hackers.

Policy routing

Policy routing enables you to redirect traffic away from a static route. This can be useful if you want to route certain types of network traffic differently. You can use incoming traffic's protocol, source address or interface, destination address, or port number to determine where to send the traffic. For example, generally network traffic would go to the router of a subnet, but you might want to direct SMTP or POP3 traffic directly to the mail server on that subnet.

If you have configured the FortiGate unit with routing policies and a packet arrives at the FortiGate unit, the FortiGate unit starts at the top of the Policy Route list and attempts to match the packet with a policy. If a match is found and the policy contains enough information to route the packet (a minimum of the IP address of the next-hop router and the FortiGate interface for forwarding packets to it), the FortiGate unit routes the packet using the information in the policy. If no policy route matches the packet, the FortiGate unit routes the packet using the routing table.

Most policy settings are optional, and a matching policy alone might not provide enough information for forwarding the packet. In fact, the FortiGate almost always requires a matching route in the routing table in order to use a policy route. The FortiGate unit will refer to the routing table in an attempt to match the information in the packet header with a route in the routing table.

Policy route options define which attributes of a incoming packet cause policy routing to occur. If the attributes of a packet match all the specified conditions, the FortiGate unit routes the packet through the specified interface to the specified gateway.

To view policy routes go to **Network > Policy Routes**.

Create New	Add a policy route. See Adding a policy route on page 362.
Edit	Edit the selected policy route.
Delete	Delete the selected policy route.
Move To	Move the selected policy route. Enter the new position and select **OK**. For more information, see Moving a policy route on page 364.

#	The ID numbers of configured route policies. These numbers are sequential unless policies have been moved within the table.
Incoming	The interfaces on which packets subjected to route policies are received.
Outgoing	The interfaces through which policy routed packets are routed.
Source	The IP source addresses and network masks that cause policy routing to occur.
Destination	The IP destination addresses and network masks that cause policy routing to occur.

Adding a policy route

To add a policy route, go to **Network > Policy Route** and select **Create New**.

Protocol	Select from existing or specify the protocol number to match. The Internet Protocol Number is found in the IP packet header. RFC 5237 describes protocol numbers and you can find a list of the assigned protocol numbers here. The range is from 0 to 255. A value of `0` disables the feature. Commonly used **Protocol** settings include 6 for TCP sessions, 17 for UDP sessions, 1 for ICMP sessions, 47 for GRE sessions, and 92 for multicast sessions.
Incoming Interface	Select the name of the interface through which incoming packets subjected to the policy are received.
Source Address / Mask	To perform policy routing based on IP source address, type the source address and network mask to match. A value of `0.0.0.0/0.0.0.0` disables the feature.
Destination Address / Mask	To perform policy routing based on the IP destination address of the packet, type the destination address and network mask to match. A value of `0.0.0.0/0.0.0.0` disables the feature.
Destination Ports	To perform policy routing based on the port on which the packet is received, type the same port number in the From and To fields. To apply policy routing to a range of ports, type the starting port number in the From field and the ending port number in the To field. A value of 0 disables this feature. The Destination Ports fields are only used for TCP and UDP protocols. The ports are skipped over for all other protocols.
Type of Service	Use a two digit hexadecimal bit pattern to match the service, or use a two digit hexadecimal bit mask to mask out. For more information, see Type of Service on page 363.

Outgoing Interface	Select the name of the interface through which packets affected by the policy will be routed.
Gateway Address	Type the IP address of the next-hop router that the FortiGate unit can access through the specified interface.

Example policy route

Configure the following policy route to send all FTP traffic received at `port1` out the `port10` interface and to a next hop router at IP address `172.20.120.23`. To route FTP traffic set protocol to 6 (for TCP) and set both of the destination ports to 21, the FTP port.

Protocol	6
Incoming interface	port1
Source address / mask	0.0.0.0/0.0.0.0
Destination address / mask	0.0.0.0/0.0.0.0
Destination Ports	From 21 to 21
Type of Service	bit pattern: 00 (hex) bit mask: 00 (hex)
Outgoing interface	port10
Gateway Address	172.20.120.23

Type of Service

Type of service (TOS) is an 8-bit field in the IP header that enables you to determine how the IP datagram should be delivered, with such qualities as delay, priority, reliability, and minimum cost.

Each quality helps gateways determine the best way to route datagrams. A router maintains a ToS value for each route in its routing table. The lowest priority TOS is 0, the highest is 7 - when bits 3, 4, and 5 are all set to 1. The router tries to match the TOS of the datagram to the TOS on one of the possible routes to the destination. If there is no match, the datagram is sent over a zero TOS route.

Using increased quality may increase the cost of delivery because better performance may consume limited network resources. For more information, see RFC 791 and RFC 1349.

The role of each bit in the IP header TOS 8-bit field

bits 0, 1, 2	**Precedence**	Some networks treat high precedence traffic as more important traffic. Precedence should only be used within a network, and can be used differently in each network. Typically you do not care about these bits.
bit 3	**Delay**	When set to 1, this bit indicates low delay is a priority. This is useful for such services as VoIP where delays degrade the quality of the sound.

bit 4	**Throughput**	When set to 1, this bit indicates high throughput is a priority. This is useful for services that require lots of bandwidth such as video conferencing.
bit 5	**Reliability**	When set to 1, this bit indicates high reliability is a priority. This is useful when a service must always be available such as with DNS servers.
bit 6	**Cost**	When set to 1, this bit indicates low cost is a priority. Generally there is a higher delivery cost associated with enabling bits 3,4, or 5, and bit 6 indicates to use the lowest cost route.
bit 7	**Reserved for future use**	Not used at this time.

For example, if you want to assign low delay, and high reliability, say for a VoIP application where delays are unacceptable, you would use a bit pattern of xxx1x1xx where an 'x' indicates that bit can be any value. Since all bits are not set, this is a good use for the bit mask; if the mask is set to 0x14, it will match any TOS packets that are set to low delay and high reliability.

Moving a policy route

A routing policy is added to the bottom of the routing table when it is created. If you prefer to use one policy over another, you may want to move it to a different location in the routing policy table.

The option to use one of two routes happens when both routes are a match, for example `172.20.0.0/255.255.0.0` and `172.20.120.0/255.255.255.0`. If both of these routes are in the policy table, both can match a route to `172.20.120.112` but you consider the second one as a better match. In that case the best match route should be positioned before the other route in the policy table.

To change the position of a policy route in the table, go to **Network> Policy Routes** and select **Move To** for the policy route you want to move.

Before/After	Select Before to place the selected Policy Route before the indicated route. Select After to place it following the indicated route.
Policy route ID	Enter the Policy route ID of the route in the Policy route table to move the selected route before or after.

Transparent mode static routing

FortiOS operating modes allow you to change the configuration of your FortiGate unit depending on the role it needs to fill in your network.

NAT/Route operating mode is the standard mode where all interfaces are accessed individually, and traffic can be routed between ports to travel from one network to another.

In transparent operating mode, all physical interfaces act like one interface. The FortiGate unit essentially becomes a bridge — traffic coming in over any interface is broadcast back out over all the interfaces on the FortiGate unit.

In transparent mode, there is no entry for routing at the main level of the menu on the web-based manager display as there is in NAT/Route mode. Routing is instead accessed through the network menu option.

To view the routing table in transparent mode, go to **Network > Routing Table**.

When viewing or creating a static route entry in transparent mode there are only three fields available.

Destination IP / Mask	The destination of the traffic being routed. The first entry is attempted first for a match, then the next, and so on until a match is found or the last entry is reached. If no match is found, the traffic will not be routed. Use 0.0.0.0 to match all traffic destinations. This is the default route.
Gateway	Specifies the next hop for the traffic. Generally the gateway is the address of a router on the edge of your network.
Priority	The priority is used if there is more than one match for a route. This allows multiple routes to be used, with one preferred. If the preferred route is unavailable the other routes can be used instead. Valid range of priority can be from 0 to 4 294 967 295. If more than one route matches and they have the same priority it becomes an ECMP situation and traffic is shared among those routes. See Transparent mode static routing on page 364.

When configuring routing on a FortiGate unit in transparent mode, remember that all interfaces must be connected to the same subnet. That means all traffic will be coming from and leaving on the same subnet. This is important because it limits your static routing options to only the gateways attached to this subnet. For example, if you only have one router connecting your network to the Internet then all static routing on the FortiGate unit will use that gateway. For this reason static routing on FortiGate units in transparent mode may be a bit different, but it is not as complex as routing in NAT/Route mode.

Static routing example

This is an example of a typical small network configuration that uses only static routing.

This network is in a dentist office that includes a number of dentists, assistants, and office staff. The size of the office is not expected to grow significantly in the near future, and the network usage is very stable—there are no new applications being added to the network.

The users on the network are:

- Admin staff - access to local patient records, and perform online billing
- Dentists - access and update local patient records, research online from desk
- Assistants - access and update local patient records in exam rooms

The distinction here is mainly that only the admin staff and dentist's office need access to the Internet—all the other traffic is local and doesn't need to leave the local network. Routing is only required for the outbound traffic, and the computers that have valid outbound traffic.

Configuring routing only on computers that need it acts as an additional layer of security by helping prevent malicious traffic from leaving the network.

This section includes the following topics:

- Network layout and assumptions
- General configuration steps
- Configure FortiGate unit
- Configure Admin PC and Dentist PCs
- Testing network configuration

Network layout and assumptions

The computers on the network are admin staff computers, dentist office computers, and dental exam room computers. While there are other devices on the local network such as printers, they do not need Internet access or any routing.

This networked office equipment includes 1 admin staff PC, 3 dentist PCs, and 5 exam room PCs. There are also a network printer, and a router on the network as well.

Assumptions about these computers, and network include:

- The FortiGate unit is a model with interfaces labeled port1 and port2.
- The FortiGate unit has been installed and is configured in NAT/Route mode.
- VDOMs are not enabled.
- The computers on the network are running MS Windows software.
- Any hubs required in the network are not shown in the network diagram.
- The network administrator has access to the ISP IP addresses, and is the super_admin administrator on the FortiGate unit.

Static routing example device names, IP addresses, and level of access

Device Name(s)	IP address	Need external access?
Router	192.168.10.1	YES
Admin	192.168.10.11	YES
Dentist1-3	192.168.10.21-23	YES
Exam1-5	192.168.10.31-35	NO
Printer	192.168.10.41	NO

General configuration steps

The steps to configuring routing on this network are:

1. Get your ISP information such as DNS, gateway, etc.
2. Configure FortiGate unit
3. Configure Admin PC and Dentist PCs
4. Testing network configuration

Get your ISP information such as DNS, gateway, etc.

Your local network connects to the Internet through your Internet Service Provider (ISP). They have IP addresses that you need to configure your network and routing.

The addresses needed for routing are your assigned IP address, DNS servers, and the gateway.

Configure FortiGate unit

The FortiGate unit will have two interfaces in use—one connected to the internal network and one connected to the external network. Port1 will be the internal interface, and port2 will be the external interface.

To configure the FortiGate unit:

1. Configure the internal interface (port1)
2. Configure the external interface (port2)
3. Configure networking information
4. Configure basic security policies
5. Configure static routing

Configure the internal interface (port1)

To configure the internal interface (port1) - web based manager

1. Go to **Network > Interfaces**. Highlight **port1** and select **Edit**.
2. Enter the following:

Addressing Mode	Manual
IP/Netmask	172.100.1.1/255.255.255.0
Administrative Access	HTTPS, PING, TELNET
Description	Internal network

To configure the internal interface (port1) - CLI

```
config system interface
   edit port1
      set IP 192.168.10.1 255.255.255.0
      set allowaccess https ping telnet
      set description "internal network"
   end
end
```

Configure the external interface (port2)

The external interface connects to your ISP's network. You need to know the IP addresses in their network that you should connect to. Use their addresses when you get them, however for this example we will assume the address your ISP gave you is 172.100.20.20 will connect to the gateway at 172.100.20.5 on their network, and their DNS servers are 172.11.22.33 and 172.11.22.34.

To configure the internal interface (port2) - web based manager

1. Go to **Network > Interfaces**. Highlight **port2** and select **Edit**.
2. Enter the following:

Addressing Mode	Manual
IP/Netmask	172.100.20.20/255.255.255.0
Administrative Access	HTTPS, PING, TELNET
Description	Internal network

To configure the internal interface (port2) - CLI

```
configure system interface
   edit port2
      set IP 172.100.20.20 255.255.255.0
      set allowaccess https ping telnet
      set description "internal network"
   end
end
```

Configure networking information

Networking information includes the gateway, and DNS servers. Your FortiGate unit requires a connection to the Internet for antivirus and other periodic updates.

To configure networking information - web-based manager

1. Go to **Network > DNS**.
2. Enter the primary and secondary DNS addresses.
3. Select **Apply**.

To configure networking information - CLI

```
config system global
   set dns_1 172.11.22.33
   set dns_2 172.11.22.34
end
```

Configure basic security policies

For traffic to flow between the internal and external ports in both directions, two security policies are required as a minimum. More can be used to farther limit or direct traffic as needed, but will not be included here.

Before configuring the security policies, a firewall address group is configured for the PCs that are allowed Internet access. This prevents PC without Internet privileges from accessing the Internet.

The security policy assumptions are:

- Only the basic networking services have been listed as allowed for added security. Others can easily be added as the users require them.

- In this example to keep things simple, both incoming and outgoing security policies are the same. In a real network there are applications that are allowed out but not in, and vice versa.
- Endpoint control has been enabled to ensure that all computers on the local network are running FortiClient and those installs are up to date. This feature ensures added security on your local network without the need for the network administrator to continually bother users to update their software. The FortiGate unit can store an up to date copy of the FortiClient software and offer a URL to it for users to install it if they need to.

To configure security policies - web-based manager

1. Go to **Policy & Objects > Objects > Addresses**.
2. Create a new Firewall Address entry for each of:

PC Name	IP Address	Interface
Admin	192.168.10.11	port1
Dentist1	192.168.10.21	port1
Dentist2	192.168.10.22	port1
Dentist3	192.168.10.23	port1

3. Go to **Policy & Objects > Objects > Addresses**.
4. Select the dropdown arrow next to **Create New** and select **Address Group**.
5. Name the group Internet_PCs.
6. Add Admin, Dentist1, Dentist2, and Dentist3 as members of the group.
7. Select **OK**.
8. Go to **Policy & Objects > Policy > IPv4**.
9. Select **Create New**.
10. Enter the following: DH - port2(external) -> port1(internal)

Incoming Interface	port2
Source Address	all
Outgoing Interface	port1
Destination Address	Internet_PCs
Schedule	always
Service	Multiple. Select **DHCP, DNS,FTP, HTTP, HTTPS, NTP, POP3, SMTP, SSH.**
Action	ACCEPT
Log Allowed Traffic	Enabled

11. Select **OK**.
12. Select **Create New**.

13. Enter the following:

Incoming Interface	port1
Source Address	Internet_PCs
Outgoing Interface	port2
Destination Address	all
Schedule	always
Service	Multiple. Select **DHCP, DNS,FTP, HTTP, HTTPS, NTP, POP3, SMTP, SSH.**
Action	ACCEPT
Log Allowed Traffic	Enabled

14. Select **OK**.

To configure security policies - CLI

```
config firewall address
   edit "Admin"
      set associated-interface "port1"
      set subnet 192.168.10.11 255.255.255.255
   next
   edit "Dentist1"
      set associated-interface "port1"
      set subnet 192.168.10.21 255.255.255.255
   next
   edit "Dentist2"
      set associated-interface "port1"
      set subnet 192.168.10.22 255.255.255.255
   next
   edit "Dentist3"
      set associated-interface "port1"
      set subnet 192.168.10.23 255.255.255.255
   end
config firewall addrgrp
   edit Internet_PCs
      set member Admin Dentist1 Dentist2 Dentist3
   end
config firewall policy
   edit 1
      set srcintf port1
      set dstintf port2
      set srcaddr Internet_PCs
      set dstaddr all
      set action accept
      set schedule always
      set service "DHCP" "DNS" "FTP" "HTTP" "HTTPS" "NTP" "POP3" "SMTP" "SSH"
      set logtraffic enable
      set label "Section2"
```

```
        set endpoint-restrict-check no-av db-outdated
    next
    edit 2
        set srcintf port2
        set dstintf port1
        set srcaddr all
        set dstaddr Internet_PCs
        set action accept
        set schedule always
        set service "DHCP" "DNS" "FTP" "HTTP" "HTTPS" "NTP" "POP3" "SMTP" "SSH"
        set logtraffic enable
        set label "Section2"
        set endpoint-restrict-check no-av db-outdated
    end
end
```

Configure static routing

With the rest of the FortiGate unit configured, static routing is the last step before moving on to the rest of the local network. All traffic on the local network will be routed according to this static routing entry.

To configure Fortinet unit static routing - web-based manager

1. Go to **Network > Static Routes**.
2. Select **Edit** for the top route on the page.
3. Enter the following:

Destination IP/Mask	172.100.20.5
Device	port2
Gateway	172.100.20.5
Distance	10

4. Select **OK**.

To configure Fortinet unit static routing - CLI

```
configure routing static
    edit 1
        set gateway 172.100.20.5
        set distance 10
        set device port2
        set dst 0.0.0.0
    end
end
```

Configure Admin PC and Dentist PCs

With the router configured, next we need to configure the computers that need Internet access. These computers need routing to be configured on them. As the other computers do not require routing, they are not included here.

The procedure to configure these computers is the same. Repeat the following procedure for the corresponding PCs.

The Windows CLI procedure does not configure the DNS entries. It just adds the static routes.

To configure routing and DNS on Admin and Dentist PCs - Windows GUI

1. On PC, select **Start > Control Panel > Network Connections**.
2. Right click on the network connection to your local network that has a status of Connected, and select **Properties**.
3. Under the **General** tab, from the list select **TCP/IP**, and **Properties**.
4. Under **Gateway**, enter the FortiGate unit address (192.168.10.1).
5. Enter the primary and secondary DNS server addresses from your ISP (172.11.22.33 and 172.11.22.34).
6. Select **OK**.

To configure routing on Admin and Dentist PCs - Windows CLI

1. On PC, select **Start > Run**, enter "`cmd`", and select **OK**.
2. At the command prompt, type
   ```
   route ADD 0.0.0.0 MASK 0.0.0.0 172.100.20.5 METRIC 10
   route ADD 192.168.10.0 MASK 255.255.255.0 192.168.10.1 METRIC 5
   ```
3. Confirm these routes have been added. Type:
   ```
   route PRINT
   ```
   If you do not see the two routes you added, try adding them again paying attention to avoid spelling mistakes.
4. Test that you can communicate with other computers on the local network, and with the Internet. If there are no other computers on the local network, connect to the FortiGate unit.

Configure other PCs on the local network

The PCs on the local network without Internet access (the exam room PCs) can be configured now.

As this step does not require any routing, details have not been included.

Testing network configuration

There are three tests to run on the network to ensure proper connectivity.

- To test that PCs on the local network can communicate
- Test that Internet_PCs on the local network can access the Internet
- Test that non-Internet_PCs can not access the Internet

Test that PCs on the local network can communicate

1. Select any two PCs on the local network, such as Exam4 and Dentist3.
2. On the Exam4 PC, at the command prompt enter `ping 192.168.10.23.`
   The output from this command should appear similar to the following.
   ```
   Pinging 192.168.10.23 with 32 bytes of data:

   Reply from 192.168.10.23: bytes=32 time<1m TTL=255
   ```

```
Reply from 192.168.10.23: bytes=32 time<1m TTL=255
Reply from 192.168.10.23: bytes=32 time<1m TTL=255
```

3. At the command prompt enter `exit` to close the window.
4. On the Dentist3 PC, at the command prompt enter `ping 192.168.10.34.`
   The output from this command should appear similar to the following.

```
Pinging 192.168.10.34 with 32 bytes of data:

Reply from 192.168.10.34: bytes=32 time<1m TTL=255
Reply from 192.168.10.34: bytes=32 time<1m TTL=255
Reply from 192.168.10.34: bytes=32 time<1m TTL=255
```

5. At the command prompt enter `exit` to close the window.
6. Repeat these steps for all PCs on the local network.
   If the output does not appear similar to above, there is a problem with the network configuration between these two PCs.

To test that Internet_PCs on the local network can access the Internet

The easiest way to access the Internet is with an Internet browser. However, if that doesn't work its best to do a traceroute to see at what point the problem is. This can help determine if it is a networking problem such as cabling, or if its an access problem such as this PC not having Internet access.

1. Select any PC on the local network that is supposed to have Internet access, such as Admin.
2. On the Admin PC, open an Internet browser and attempt to access a website on the Internet such as http://www.fortinet.com.
   If this is successful, this PC has Internet access.
3. If step2 was not successful, at the command prompt on the PC enter `traceroute 22.11.22.33.`
   The output from this command should appear similar to:

```
Pinging 22.11.22.33 with 32 bytes of data:

Reply from 22.11.22.33: bytes=32 time<1m TTL=255
Reply from 22.11.22.33: bytes=32 time<1m TTL=255
Reply from 22.11.22.33: bytes=32 time<1m TTL=255
```

Dynamic Routing Overview

This section provides an overview of dynamic routing, and how it compares to static routing. For details on various dynamic routing protocols, see the following chapters for detailed information.

The following topics are included in this section:

What is dynamic routing?

Dynamic routing uses a dynamic routing protocol to automatically select the best route to put into the routing table. So instead of manually entering static routes in the routing table, dynamic routing automatically receives

routing updates, and dynamically decides which routes are best to go into the routing table. Its this intelligent and hands-off approach that makes dynamic routing so useful.

Dynamic routing protocols vary in many ways and this is reflected in the various administrative distances assigned to routes learned from dynamic routing. These variations take into account differences in reliability, speed of convergence, and other similar factors. For more information on these administrative distances, see Advanced Static Routing on page 2343.

This section includes:

- Comparing static and dynamic routing
- Dynamic routing protocols
- Minimum configuration for dynamic routing

Comparing static and dynamic routing

A common term used to describe dynamic routing is convergence. Convergence is the ability to work around network problems and outages — for the routing to come together despite obstacles. For example, if the main router between two end points goes down, convergence is the ability to find a way around that failed router and reach the destination. Static routing has zero convergence beyond trying the next route in its limited local routing table — if a network administrator doesn't fix a routing problem manually, it may never be fixed, resulting in a downed network. Dynamic routing solves this problem by involving routers along the route in the decision-making about the optimal route, and using the routing tables of these routers for potential routes around the outage. In general, dynamic routing has better scalability, robustness, and convergence. However, the cost of these added benefits include more complexity and some overhead: the routing protocol uses some bandwidth for its own administration.

Comparing static and dynamic routing

Feature	Static Routing	Dynamic Routing
Hardware support	Supported by all routing hardware	May require special, more expensive routers
Router Memory Required	Minimal	Can require considerable memory for larger tables
Complexity	Simple	Complex
Overhead	None	Varying amounts of bandwidth used for routing protocol updates
Scalability	Limited to small networks	Very scalable, better for larger networks
Robustness	None - if a route fails it has to be fixed manually	Robust - traffic routed around failures automatically
Convergence	None	Varies from good to excellent

Dynamic routing protocols

A dynamic routing protocol is an agreed-on method of routing that the sender, receiver, and all routers along the path (route) support. Typically the routing protocol involves a process running on all computers and routers along that route to enable each router to handle routes in the same way as the others. The routing protocol determines how the routing tables are populated along that route, how the data is formatted for transmission, and what information about a route is included with that route. For example RIP, and BGP use distance vector algorithms, where OSPF uses a shortest path first algorithm. Each routing protocol has different strengths and weaknesses — one protocol may have fast convergence, while another may be very reliable, and a third is very popular for certain businesses like Internet Service Providers (ISPs).

Dynamic routing protocols are different from each other in a number of ways, such as:

- Classful versus classless routing protocols
- Interior versus exterior routing protocols
- Distance vector versus link-state protocols

Classful versus classless routing protocols

Classful or classless routing refers to how the routing protocol handes the IP addresses. In classful addresses there is the specific address, and the host address of the server that address is connected to. Classless addresses use a combination of IP address and netmask.

Classless Inter-Domain Routing (CIDR) was introduced in 1993 (originally with RFC 1519 and most recently with RFC 4632) to keep routing tables from getting too large. With Classful routing, each IP address requires its own entry in the routing table. With Classless routing, a series of addresses can be combined into one entry potentially saving vast amounts of space in routing tables.

Current routing protocols that support classless routing out of necessity include RIPv2, BGP, IS-IS, and OSPF. Older protocols such as RIPv1 do not support CIDR addresses.

Interior versus exterior routing protocols

The names **interior** and **exterior** are very descriptive. Interior routing protocols are designed for use within a contained network of limited size, whereas exterior routing protocols are designed to link multiple networks together. They can be used in combination in order to simplify network administration. For example, a network can be built with only border routers of a network running the exterior routing protocol, while all the routers on the network run the interior protocol, which prevents them from connecting outside the network without passing through the border. Exterior routers in such a configuration must have both exterior and interior protocols, to communicate with the interior routers and outside the network.

Nearly all routing protocols are interior routing protocols. Only BGP is commonly used as an exterior routing protocol.

You may see interior gateway protocol (IGP) used to refer to interior routing protocols, and exterior gateway protocol (EGP) used to refer to interior routing protocols.

Distance vector versus link-state protocols

Every routing protocol determines the best route between two addresses using a different method. However, there are two main algorithms for determining the best route — Distance vector and Link-state.

Distance vector protocols

In distance vector protocols, routers are told about remote networks through neighboring routers. The distance part refers to the number of hops to the destination, and in more advanced routing protocols these hops can be weighted by factors such as available bandwidth and delay. The vector part determines which router is the next step along the path for this route. This information is passed along from neighboring routers with routing update packets that keep the routing tables up to date. Using this method, an outage along a route is reported back along to the start of that route, ideally before the outage is encountered.

On distance vector protocols, RFC 1058 which defines RIP v1 states the following:

> *Distance vector algorithms are based on the exchange of only a small amount of information. Each entity (gateway or host) that participates in the routing protocol is assumed to keep information about all of the destinations within the system. Generally, information about all entities connected to one network is summarized by a single entry, which describes the route to all destinations on that network.*

There are four main weaknesses inherent in the distance vector method. Firstly, the routing information is not discovered by the router itself, but is instead reported information that must be relied on to be accurate and up-to-date. The second weakness is that it can take a while for the information to make its way to all the routers who need the information — in other words it can have slow convergence. The third weakness is the amount of overhead involved in passing these updates all the time. The number of updates between routers in a larger network can significantly reduce the available bandwidth. The fourth weakness is that distance vector protocols can end up with routing-loops. Routing loops are when packets are routed for ever around a network, and often occur with slow convergence. The bandwidth required by these infinite loops will slow your network to a halt. There are methods of preventing these loops however, so this weakness is not as serious as it may first appear.

Link-state protocols

Link-state protocols are also known as shortest path first protocols. Where distance vector uses information passed along that may or may not be current and accurate, in link-state protocols each router passes along only information about networks and devices directly connected to it. This results in a more accurate picture of the network topology around your router, allowing it to make better routing decisions. This information is passed between routers using link-state advertisements (LSAs). To reduce the overhead, LSAs are only sent out when information changes, compared to distance vector sending updates at regular intervals even if no information has changed. The more accurate network picture in link-state protocols greatly speed up convergence and avoid problems such as routing-loops.

Minimum configuration for dynamic routing

Dynamic routing protocols do not pay attention to routing updates from other sources, unless you specifically configure them to do so using CLI redistribute commands within each routing protocol.

The minimum configuration for any dynamic routing to function is to have dynamic routing configured on one interface on the FortiGate unit, and one other router configured as well. Some protocols require larger networks to function as designed.

Minimum configuration based on dynamic protocol

	BGP	RIP	OSPF / IS-IS
Interface	yes	yes	yes
Network	yes	yes	yes
AS	local and neighbor	no	yes
Neighbors	at least one	at least one	at least one
Version	no	yes	no
Router ID	no	no	yes

Comparison of dynamic routing protocols

Each dynamic routing protocol was designed to meet a specific routing need. Each protocol does some things well, and other things not so well. For this reason, choosing the right dynamic routing protocol for your situation is not an easy task.

Features of dynamic routing protocols

Each protocol is better suited for some situations over others.

Choosing the best dynamic routing protocol depends on the size of your network, speed of convergence required, the level of network maintenance resources available, what protocols the networks you connect to are using, and so on. For more information on these dynamic routing protocols, see Routing Information Protocol (RIP) on page 2387, Border Gateway Protocol (BGP) on page 2465, Open Shortest Path First (OSPF) on page 2424, and Intermediate System to Intermediate System Protocol(IS-IS) on page 2502.

Comparing RIP, BGP, and OSPF dynamic routing protocols

Protocol	RIP	BGP	OSPF / IS-IS
Routing algorithm	Distance Vector, basic	Distance Vector, advanced	Link-state
Common uses	Small non-complex networks	Network backbone, ties multinational offices together	Common in large, complex enterprise networks

Protocol	RIP	BGP	OSPF / IS-IS
Strengths	Fast and simple to implement Near universal support Good when no redundant paths	Graceful restart BFD support Only needed on border routers Summarize routes	Fast convergence Robust Little management overhead No hop count limitation Scalable
Weakness	Frequent updates can flood network Slow convergence Maximum 15 hops may limit network configuration	Required full mesh in large networks can cause floods Route flap Load-balance multi-homed networks Not available on low-end routers	Complex No support for unequal cost multipath routing Route summary can require network changes
Authentication	Optional authentication using text string or MD5 password. (RIP v1 has no authentication)		
IPv6 Support	Only in RIPng	Only in BGP4+	Only in OSPF6 / Integrated IS-IS

Routing protocols

- **Routing Information Protocol (RIP)** uses classful routing, as well as incorporating various methods to stop incorrect route information from propagating, such as the poisoned horizon method. However, on larger networks its frequent updates can flood the network and its slow convergence can be a problem.
- **Border Gateway Protocol (BGP)** has been the core Internet backbone routing protocol since the mid 1990s, and is the most used interior gateway protocol (IGP). However, some configurations require full mesh connections which flood the network, and there can be route flap and load balancing issues for multihomed networks.
- **Open Shortest Path First (OSPF)** is commonly used in large enterprise networks. It is the protocol of choice mainly due to its fast convergence. However, it can be complicated to setup properly.
- **Intermediate System to Intermediate System (IS-IS) Protocol** allows routing of ISO's OSI protocol stack Connectionless Network Service (CLNS). IS-IS is an Interior Gateway Protocol (IGP) not intended to be used between Autonomous Systems (ASes). IS-IS is a link state protocol well-suited to smaller networks that is in widespread use and has near universal support on routing hardware.
- **Multicast** addressing is used to broadcast from one source to many destinations efficiently. Protocol Independent Multicast (PIM) is the protocol commonly used in enterprises, multimedia content delivery, and stock exchanges.

Routing algorithm

Each protocol uses a slightly different algorithm for choosing the best route between two addresses on the network. The algorithm is the “intelligent” part of a dynamic protocol because the algorithm is responsible for deciding which route is best and should be added to the local routing table. RIP and BGP use distance vector algorithms, where OSPF and IS-IS use link-state or a shortest path first algorithm.

Vector algorithms are essentially based on the number of hops between the originator and the destination in a route, possibly weighting hops based on how reliable, fast, and error-free they are.

The link-state algorithm used by OSPF and IS-IS is called the Dijkstra algorithm. Link-state treats each interface as a link, and records information about the state of the interface. The Dijkstra algorithm creates trees to find the shortest paths to the routes it needs based on the total cost of the parts of the routes in the tree.

For more information on the routing algorithm used, see Comparison of dynamic routing protocols on page 377.

Authentication

If an attacker gains access to your network, they can masquerade as a router on your network to either gain information about your network or disrupt network traffic. If you have a high quality firewall configured, it will help your network security and stop many of this type of threat. However, the main method for protecting your routing information is to use authentication in your routing protocol. Using authentication on your FortiGate unit and other routers prevents access by attackers — all routers must authenticate with passwords, such as MD5 hash passwords, to ensure they are legitimate routers.

When configuring authentication on your network, ensure you configure it the same on all devices on the network. Failure to do so will create errors and outages as those forgotten devices fail to connect to the rest of the network.

For example, to configure an MD5 key of `123` on an OSPF interface called `ospf_test`, enter the following CLI command:

```
config router ospf
   config ospf-interface
      edit ospf_test
         set authentication md5
         set md5-key 123
      end
   end
```

Convergence

Convergence is the ability of a networking protocol to re-route around network outages. Static routing cannot do this. Dynamic routing protocols can all converge, but take various amounts of time to do this. Slow convergence can cause problems such as network loops which degrade network performance.

You may also hear robustness and redundancy used to describe networking protocols. In many ways they are the same thing as convergence. Robustness is the ability to keep working even though there are problems, including configuration problems as well as network outages. Redundancy involves having duplicate parts that can continue to function in the event of some malfunction, error, or outage. It is relatively easy to configure dynamic routing protocols to have backup routers and configurations that will continue to function no matter the network problem short of a total network failure.

IPv6 Support

IPv4 addressing is in common use everywhere around the world. IPv6 has much larger addresses and it is used by many large companies and government departments. IPv6 is not as common as IPv4 yet, but more companies are adopting it.

If your network uses IPv6, your dynamic routing protocol must support it. None of the dynamic routing protocols originally supported IPv6, but they all have additions, expansions, or new versions that do support IPv6. For more information, see Routing Information Protocol (RIP) on page 2387, Border Gateway Protocol (BGP) on page 2465, Open Shortest Path First (OSPF) on page 2424, or Intermediate System to Intermediate System Protocol (IS-IS) on page 2502.

When to adopt dynamic routing

Static routing is more than enough to meet your networking needs when you have a small network. However, as your network grows, the question you need to answer is at what point do you adopt dynamic routing in your networking plan and start using it in your network? The main factors in this decision are typically:

- Budget
- Current network size and topology
- Expected network growth
- Available resources for ongoing maintenance

Budget

When making any business decision, the budget must always be considered. Static routing does not involve special hardware, fancy software, or expensive training courses.

Dynamic routing can include all of these extra expenses. Any new hardware, such as routers and switches, will need to support your chosen routing protocols. Network management software and routing protocol drivers may be necessary as well to help configure and maintain your more complex network. If the network administrators are not well versed in dynamic routing, either a training course or some hands-on learning time must be budgeted so they can administer the new network with confidence. Together, these factors can impact your budget.

Additionally, people will always account for network starting costs in the budgets, but usually leave out the ongoing cost of network maintenance. Any budget must provide for the hours that will be spent on updating the network routing equipment, and fixing any problems. Without that money in the budget, you may end up back at static routing before you know it.

Current network size and topology

As stated earlier static routing works well on small networks. At those networks get larger, routing takes longer, routing tables get very large, and general performance isn't what it could be.

Topology is a concern as well. If all your computers are in one building, its much easier to stay with static routing longer. However, connecting a number of locations will be easier with the move to dynamic routing.

If you have a network of 20 computers, you can still likely use static routing. If those computers are in two or three locations, static routing will still be a good choice for connecting them. Also, if you just connect to your ISP and don't worry about any special routing to do that, you are likely safe with just static routing.

If you have a network of 100 computers in one location, you can use static routing but it will be getting slower, more complex, and there won't be much room for expansion. If those 100 computers are spread across three or more locations, dynamic routing is the way to go.

If you have 1000 computers, you definitely need to use dynamic routing no matter how many locations you have.

Hopefully this section has given you an idea of what results you will likely experience from different sized networks using different routing protocols. Your choice of which dynamic routing protocol to use is partly determined by the network size, and topology.

Expected network growth

You may not be sure if your current network is ready for dynamic routing. However, if you are expecting rapid growth in the near future, it is a good idea to start planning for that growth now so you are ready for the coming expansion.

Static routing is very labor intensive. Each network device's routing table needs to be configured and maintained manually. If there is a large number of new computers being added to the network, they each need to have the static routing table configured and maintained. If devices are being moved around the network frequently, they must also be updated each time.

Instead, consider putting dynamic routing in place before those new computers are installed on the network. The installation issues can be worked out with a smaller and less complex network, and when those new computers or routers are added to the network there will be nowhere near the level of manual configuration required. Depending on the level of growth, this labor savings can be significant. For example, in an emergency you can drop a new router into a network or AS, wait for it to receive the routing updates from its neighbors, and then remove one of the neighbors. While the routes will not be the most effective possible, this method is much less work than static routing in the same situation, with less chance of mistakes.

Also, as your network grows and you add more routers, those new routers can help share the load in most dynamic routing configurations. For example if you have 4 OSPF routers and 20,000 external routes those few routers will be overwhelmed. But in a network with 15 OSPF routers they will better be able to handle that number of routes. Be aware though that adding more routers to your network will increase the amount of updates sent between the routers, which will use up a greater part of your bandwidth and use more bandwidth overall.

Available resources for ongoing maintenance

As touched on in the budget section, there must be resources dedicated to ongoing network maintenance, upgrades, and troubleshooting. These resources include administrator hours to configure and maintain the network, training for the administrator if needed, extra hardware and software as needed, and possible extra staff to help the administrator in emergencies. Without these resources, you will quickly find the network reverting to static routing out of necessity. This is because:

- Routing software updates will require time.
- Routing hardware updates will require time.
- Office reorganizations or significant personnel movement will require time from a networking point of view.
- Networking problems that occur, such as failed hardware, require time to locate and fix the problem.

If the resources to accomplish these tasks are not budgeted, they will either not happen or not happen at the required level to continue operation. This will result in both the network administration staff and the network users being very frustrated.

A lack of maintenance budget will also result in increasingly heavy reliance on static routing as the network administrators are forced to use quick fixes for problems that come up. This invariably involves going to static routing, and dropping the more complex and time-consuming dynamic routing.

Choosing a routing protocol

One of that hardest decisions in routing can be choosing which routing protocol to use on your network. It can be easy to decide when static routing will not meet your needs, but how can you tell which dynamic routing protocol is best for your network and situation?

Here is a brief look at the routing protocols including their strongest and weakest points. The steps to choosing your routing protocol are:

1. Answer questions about your network
2. Evaluate your chosen protocol
3. Implement your dynamic routing protocol

Answer questions about your network

Before you can decide what is best for your situation, you need to examine what the details of your situation are such as what you have for budget, equipment, and users.

The following questions will help you form a clear idea of your routing needs:

How many computers or devices are on your network?

It matters if you only have a few computers, or if you have many and if they are all at one location or not as well. All routing protocols can be run on any sized network, however it can be inefficient to run some on very small networks. However, routers and network hardware that support dynamic routing can be more expensive than more generic routers for static routing.

What applications typically run over the network?

Finding out what application your users are running will help you determine their needs and the needs of the network regarding bandwidth, quality of service, and other such issues.

What level of service do the users expect from the network?

Different network users have different expectations of the network. Its not critical for someone surfing the Internet to have 100% uptime, but it is required for a stock exchange network or a hospital.

Is there network expansion in your near future?

You may have a small network now, but if it will be growing quickly, you should plan for the expected size so you don't have to chance technologies again down the road.

What routing protocols do your networks connect to?

This is most often how routing protocol decisions are made. You need to be able to communicate easily with your service provider and neighbors, so often people simply use what everyone else is using.

Is security a major concern?

Some routing protocols have levels of authentication and other security features built in. Others do not. If security is important to you, be aware of this.

What is your budget — both initial and maintenance?

More robust and feature laden routing protocols generally mean more resources are required to keep them working well. Also more secure configurations require still more resources. This includes both set up costs, as well as ongoing maintenance costs. Ignore these costs at the risk of having to drop the adoption of the new routing protocol mid-change.

Evaluate your chosen protocol

Once you have examined the features of the routing protocols listed above and chosen the one that best meets your needs, you can set up an evaluation or test install of that protocol.

The test install is generally set up in a sandbox configuration so it will not affect critical network traffic. The aim of the test install is to prove that it will work on a larger scale on your network. So be sure that the test install mirrors your larger network well enough for you to discover any problems. If its too simplistic, these problems may not appear.

If your chosen protocol does not meet your goals choose a different protocol and repeat the evaluation process until either a protocol meets your needs, or you change your criteria.

Implement your dynamic routing protocol

You have examined your needs, selected the best matching dynamic routing protocol, tested it, and now you are ready to implement it with confidence.

This guide will help you configure your FortiGate unit to support your chosen dynamic routing protocol. Refer to the various sections in this guide as needed during your implementation to help ensure a smooth transition. Examples for each protocol have been included to show proper configurations for different types of networks.

Dynamic routing terminology

Dynamic routing is a complex subject. There are many routers on different networks and all can be configured differently. It become even more complicated when you add to this each routing protocol having slightly different names for similar features, and many configurable features for each protocol.

To better understand dynamic routing, here are some explanations of common dynamic routing terms.

- Aggregated routes and addresses
- Autonomous system (AS)
- Area border router (ABR)
- Neighbor routers
- Route maps
- Access lists
- Bi-directional forwarding detection (BFD)

For more details on a term as it applies to a dynamic routing protocol, see one of Border Gateway Protocol (BGP) on page 2465, Routing Information Protocol (RIP) on page 2387, or Open Shortest Path First (OSPF) on page 2424.

Aggregated routes and addresses

Just as an aggregate interface combines multiple interfaces into one virtual interface, an aggregate route combines multiple routes into one. This reduces the amount of space those routes require in the routing tables of

the routers along that route. The trade-off is a small amount of processing to aggregate and de-aggregate the routes at either end.

The benefit of this method is that you can combine many addresses into one, potentially reducing the routing table size immensely. The weakness of this method is if there are holes in the address range you are aggregating you need to decide if its better to break it into multiple ranges, or accept the possibility of failed routes to the missing addresses.

For information on aggregated routes in BGP, see Border Gateway Protocol (BGP) on page 2465, and Border Gateway Protocol (BGP) on page 2465.

To manually aggregate the range of IP addresses from 192.168.1.100 to 192.168.1.103

1. Convert the addresses to binary
   ```
   192.168.1.100 = 11000000 10101000 00000001 01100100
   192.168.1.101 = 11000000 10101000 00000001 01100101
   192.168.1.102 = 11000000 10101000 00000001 01100110
   192.168.1.103 = 11000000 10101000 00000001 01100111
   ```
2. Determine the maximum number of matching bits common to the addresses.
   There are 30-bits in common, with only the last 2-bits being different.
3. Record the common part of the address.
   ```
   11000000 10101000 00000001 0110010X = 192.168.1.100
   ```
4. For the netmask, assume all the bits in the netmask are 1 except those that are different which are 0.
   ```
   11111111 11111111 11111111 11111100 = 255.255.255.252
   ```
5. Combine the common address bits and the netmask.
   ```
   192.168.1.100/255.255.255.252
   ```
   Alternately the IP mask may be written as a single number:
   ```
   192.168.1.100/2
   ```
6. As required, set variables and attributes to declare the routes have been aggregated, and what router did the aggregating.

Autonomous system (AS)

An Autonomous System (AS) is one or more connected networks that use the same routing protocol, and appear to be a single unit to any externally connected networks. For example an ISP may have a number of customer networks connected to it, but to any networks connected externally to the ISP it appears as one system or AS. An AS may also be referred to as a routing domain.

It should be noted that while OSPF routing takes place within one AS, the only part of OSPF that deals with the AS is the AS border router (ASBR).

There are multiple types of AS defined by how they are connected to other ASes. A multihomed AS is connected to at least two other ASes and has the benefit of redundancy — if one of those ASes goes down, your AS can still reach the Internet through its other connection. A stub AS only has one connection, and can be useful in specific configurations where limited access is desirable.

Each AS has a number assigned to it, known as an ASN. In an internal network, you can assign any ASN you like (a private AS number), but for networks connected to the Internet (public AS) you need to have an officially

registered ASN from Internet Assigned Numbers Authority (IANA). ASNs from 1 to 64,511 are designated for public use.

NAs of January 2010, AS numbers are 4 bytes long instead of the former 2 bytes. RFC 4893 introduced 32-bit ASNs, which FortiGate units support for BGP and OSPF.

Do you need your own AS?

The main factors in deciding if you need your own AS or if you should be part of someone else's are:

- exchanging external routing information
- many prefixes should exist in one AS as long as they use the same routing policy
- when you use a different routing protocol than your border gateway peers (for example your ISP uses BGP, and you use OSPF)
- connected to multiple other AS (multi-homed)

You should not create an AS for each prefix on your network. Neither should you be forced into an AS just so someone else can make AS-based policy decisions on your traffic.

There can be only one AS for any prefix on the Internet. This is to prevent routing issues.

What AS number to use?

In addition to overseeing IP address allocation and Domain Name Systems (DNS), the Internet Assigned Numbers Authority (IANA) assigns public AS numbers. The public AS numbers are from 1 to 64,511. The ASNs 0, 54272–64511, and 65535 are reserved by the IANA. These ASNs should not be used.

ASNs are assigned in blocks by the Internet Assigned Numbers Authority (IANA) to Regional Internet Registries (RIRs) who then assign ASNs to companies within that RIRs geographic area. Usually these companies are ISPs, and to receive an ASN you must complete the application process of the local RIR and be approved before being assigned an ASN. The RIRs names and regions are:

AFRINIC	Serves the African continent
APNIC	Asia-Pacific including China, India, and Japan
ARIN	American registry including Canada and United States
LACNIC	Latin America, including Mexico, Caribbean, Central and South America
RIPE NCC	Europe, the Middle East, former USSR, and parts of Central Asia

AS numbers from 64512 to 65534 are reserved for private use. Private AS numbers can be used for any internal networks with no outside connections to the Internet such as test networks, classroom labs, or other internal-only networks that do not access the outside world. You can also configure border routers to filter out any private ASNs before routing traffic to the outside world. If you must use private ASNs with public networks, this is the only way to configure them. However, it is risky because many other private networks could be using the same ASNs and conflicts will happen. It would be very much like your local 192.168.0.0 network being made public — the resulting problems would be widespread.

In 1996, when RFC 1930 was written only 5,100 ASes had been allocated and a little under 600 ASes were actively routed in the global Internet. Since that time many more public ASNs have been assigned, leaving only a small number. For this reason 32-bit ASNs (four-octet ASNs) were defined to provide more public ASNs. RFC 4893 defines 32-bit ASNs, and FortiGate units support these larger ASNs.

Area border router (ABR)

Routers within an AS advertise updates internally and only to each other. However, routers on the edge of the AS must communicate both with routers inside their AS and with routers external to their AS, often running a different routing protocol. These routers are called Area Border Routers (ABRs) or edge routers. Often ABRs run multiple routing protocols to be able to redistribute traffic between different ASes that are running different protocols, such as the edge between an ISP's IS-IS routing network and a large company's OSPF network.

OSPF defines ABRs differently from other routers. In OSPF, an ABR is an OSPF router that connects another AS to the backbone AS, and is a member of all the areas it connects to. An OSPF ABR maintains a LSA database for each area that it is connected to. The concept of the edge router is present, but its the edge of the backbone instead of the edge of the OSPF supported ASes.

Neighbor routers

Routing involves routers communicating with each other. To do this, routers need to know information about each other. These routers are called neighbor routers, and are configured in each routing protocol. Each neighbor has custom settings since some routers may have functionality others routers lack. Neighbor routers are sometimes called peers.

Generally neighbor routers must be configured, and discovered by the rest of the network before they can be integrated to the routing calculations. This is a combination of the network administrator configuring the new router with its neighbor router addresses, and the routing network discovering the new router, such as the hello packets in OSPF. That discovery initiates communication between the new router and the rest of the network.

Route maps

Route maps are a way for the FortiGate unit to evaluate optimum routes for forwarding packets or suppressing the routing of packets to particular destinations. Compared to access lists, route maps support enhanced packet-matching criteria. In addition, route maps can be configured to permit or deny the addition of routes to the FortiGate unit routing table and make changes to routing information dynamically as defined through route-map rules.

Route maps can be used for limiting both received route updates, and sent route updates. This can include the redistribution of routes learned from other types of routing. For example if you don't want to advertise local static routes to external networks, you could use a route map to accomplish this.

The FortiGate unit compares the rules in a route map to the attributes of a route. The rules are examined in ascending order until one or more of the rules in the route map are found to match one or more of the route attributes.

As an administrator, route maps allow you to group a set of addresses together and assign them a meaningful name. Then during your configuration, you can use these route-maps to speed up configuration. The meaningful names ensure fewer mistakes during configuration as well.

The default rule in the route map (which the FortiGate unit applies last) denies all routes. For a route map to take effect, it must be called by a FortiGate unit routing process.

The syntax for route maps are:

```
config router route-map
   edit <route_map_name>
      set comments
      config rule
         edit <route_map_rule_id>
            set action
            set match-*
            set set-*
            ...
         end
```

The `match-*` commands allow you to match various parts of a route. The `set-*` commands allow you to set routing information once a route is matched.

For an example of how route maps can be used to create receiving or sending “groups” in routing, see Border Gateway Protocol (BGP) on page 2465.

Access lists

Use this command to add, edit, or delete access lists. Access lists are filters used by FortiGate unit routing processes. For an access list to take effect, it must be called by a FortiGate unit routing process (for example, a process that supports RIP or OSPF). Use `access-list6` for IPv6 routing.

Access lists can be used to filter which updates are passed between routers, or which routes are redistributed to different networks and routing protocols. You can create lists of rules that will match all routes for a specific router or group of routers.

Each rule in an access list consists of a prefix (IP address and netmask), the action to take for this prefix (permit or deny), and whether to match the prefix exactly or to match the prefix and any more specific prefix.

If you are setting a prefix of 128.0.0.0, use the format 128.0.0.0/1. The default route, 0.0.0.0/0 can not be exactly matched with an access-list. A prefix-list must be used for this purpose.

The FortiGate unit attempts to match a packet against the rules in an access list starting at the top of the list. If it finds a match for the prefix, it takes the action specified for that prefix. If no match is found the default action is deny.

The syntax for access lists is:

```
config router access-list, access-list6
   edit <access_list_name>
      set comments
      config rule
      edit <access_list_id>
         set action
         set exact-match
         set prefix
         set prefix6
         set wildcard
```

For an example of how access lists can be used to create receiving or sending “groups” in routing, see Border Gateway Protocol (BGP) on page 2465.

Bi-directional forwarding detection (BFD)

Bi-directional Forwarding Detection (BFD) is a protocol used to quickly locate hardware failures in the network. Routers running BFD send packets to each other at a negotiated rate. If packets from a BFD-protected router fail to arrive, then that router is declared down. BFD communicates this information to the routing protocol and the routing information is updated.

BFD neighbors establish if BFD is enabled in OSPF or BFP routers that establish as neighbors.

The CLI commands associated with BFD include:

```
config router bgp
   config neighbor
      set bfd
end
config router ospf
   set bfd
end
```

Per-VDOM configuration:

```
config system settings
   set bfd
   set bfd-desired-min-tx
   set bfd-required-min-rx
   set bfd-detect-mult
   set bfd-dont-enforce-src-port
end
```

Per-interface (override) configuration:

```
config system interface
   edit <interface_name>
      set bfd enable
      set bfd-desired-min-tx
      set bfd-detect-mult
      set bfd-required-min-rx
   end
```

For more information about BFD in BGP, see Border Gateway Protocol (BGP) on page 2465.

IPv6 in dynamic routing

Unless otherwise stated, routing protocols apply to IPv4 addressing. This is the standard address format used. However, IPv6 is becoming more popular and new versions of the dynamic routing protocols have been introduced.

Dynamic routing supports IPv6 on your FortiGate unit. The new versions of these protocols and the corresponding RFCs are:

- **RIP next generation (RIPng)** — RFC 2080 - Routing Information Protocol next generation (RIPng). See RIP and IPv6.
- **BGP4+** — RFC 2545, and RFC 2858 Multiprotocol Extensions for IPv6 Inter-Domain Routing, and Multiprotocol Extensions for BGP-4 (MP-BGP) respectively. See BGP and IPv6.
- **OSPFv3** — RFC 2740 Open Shortest Path First version 3 (OSPFv3) for IPv6 support. See OSPFv3 and IPv6.
- **Integrated IS-IS** — RFC 5308 for IPv6 support. See Integrated IS-IS.

As with most advanced routing features on your FortiGate unit, IPv6 settings for dynamic routing protocols must be enabled before they will be visible in the GUI. To enable IPv6 configuration in the GUI, enable it in **System >**

Feature Select. Alternatively, you can directly configure IPv6 for RIP, BGP, or OSPF protocols using CLI commands.

Routing Information Protocol (RIP)

This section describes the Routing Information Protocol (RIP).

The following topics are included in this section:

RIP background and concepts

This section contains:

- Background
- Parts and terminology of RIP
- How RIP works

Background

Routing Information Protocol (RIP) is a distance-vector routing protocol intended for small, relatively homogeneous networks. Its widespread use started when an early version of RIP was included with BSD v4.3 Linux as the routed daemon. The routing algorithm used by RIP, the Bellman–Ford algorithm, first saw widespread use as the initial routing algorithm of the ARPANET.

RIP benefits include being well suited to smaller networks, is in widespread use, near universal support on routing hardware, quick to configure, and works well if there are no redundant paths. However, RIP updates are sent out node-by-node so it can be slow to find a path around network outages. RIP also lacks good authentication, can not choose routes based on different quality of service methods, and can create network loops if you are not careful.

The FortiGate implementation of RIP supports RIP version 1 (see RFC 1058), RIP version 2 (see RFC 2453), and the IPv6 version RIPng (see RFC 2080).

RIP v1

In 1988 RIP version 1, defined in RFC 1058, was released. The RFC even states that RIP v1 is based on Linux routed due to it being a “defacto standard”.

It uses classful addressing and uses broadcasting to send out updates to router neighbors. There is no subnet information included in the routing updates in classful routing, and it does not support CIDR addressing — subnets must all be the same size. Also, route summarization is not possible.

RIP v1 has no router authentication method, so it is vulnerable to attacks through packet sniffing, and spoofing.

RIP v2

In 1993, RIP version 2 was developed to deal with the limitations of RIP v1. It was not standardized until 1998. This new version supports classless routing, and subnets of various sizes.

Router authentication was added in RIP v2 — it supports MD5. MD5 hashes are an older encryption method, but this is much improved over no security at all.

In RIP v2 the hop count limit remained at 15 to be backwards compatible with RIP v1.

RIP v2 uses multicasting to send the entire routing table to router neighbors, thereby reducing the traffic for devices that are not participating in RIP routing.

Routing tags were added as well, which allow internal routes or redistributed routes to be identified as such.

RIPng

RIPng, defined in RFC 2080, is an extension of RIP2 designed to support IPv6. However, RIPng varies from RIPv2 in that it is not fully backwards compatible with RIPv1.

- RIPng does not support RIPv1 update authentication, it relies on IPsec
- RIPng does not allow attaching tags to routes as in RIPv2
- RIPng requires specific encoding of the next hop for a set of route entries, unlike RIPv2 that encodes the next-hop into each route entry.

Parts and terminology of RIP

Before you can understand how RIP functions, you need to understand some of the main concepts and parts of RIP.

This section includes:

- RIP and IPv6
- Default information originate option
- Update, Timeout, and Garbage timers
- Authentication and key-chain
- Access Lists

RIP and IPv6

RIP Next Generation (RIPng) is a new version of RIP was released that includes support for IPv6.

The FortiGate unit command `config router ripng` is almost the same as `config router rip`, except that IPv6 addresses are used. Also if you are going to use prefix or access lists with RIPng, you must use the `config router access-list6` or `config prefix-list6` versions of those commands.

If you want to troubleshoot RIPng, it is the same as with RIP but specify the different protocol, and use IPv6 addresses. This applies to commands such as `get router info6` when you want to see the routing table, or other related information.

If you want to route IPv4 traffic over an IPv6 network, you can use the command `config system ip6-tunnel` to configure the FortiGate unit to do this. The IPv6 interface is configured under `config system interface`. All subnets between the source and destination addresses must support IPv6. This command is not supported in Transparent mode.

For example, you want to set up a tunnel on the port1 interface starting at 2002:C0A8:3201:: on your local network and tunnel it to address 2002:A0A:A01:: where it will need access to an IPv4 network again. Use the following command:

```
config system ipv6-tunnel
   edit test_tunnel
      set destination 2002:A0A:A01::
      set interface port1
      set source 2002:C0A8:3201::
```

```
    end
end
```

The CLI commands associated with RIPng include:

```
config router ripng
config router access-list6
config router prefix-list6
config system ipv6-tunnel
get router info6 *
```

Default information originate option

This is the second advanced option for RIP in the web-based manager, right after metric. Enabling default-information-originate will generate and advertise a default route into the FortiGate unit's RIP-enabled networks. The generated route may be based on routes learned through a dynamic routing protocol, routes in the routing table, or both. RIP does not create the default route unless you use the always option.

Select **Disable** if you experience any issues or if you wish to advertise your own static routes into RIP updates.

You can enable or disable default-information-originate in **Network > RIP**, under **Advanced Options**, or use the CLI.

The CLI commands associated with default information originate include:

```
config router rip
   set default-information-originate
end
```

Update, Timeout, and Garbage timers

RIP uses various timers to regulate its performance including an update timer, a timeout timer, and a garbage timer. The FortiGate unit default timer settings (30, 180, and 120 seconds respectively) are effective in most configurations — if you change these settings, ensure that the new settings are compatible with local routers and access servers.

The Timeout period should be at least three times longer than the Update period. If the Update timer is smaller than Timeout or Garbage timers, you will experience an error.

You can set the three RIP timers in **Network > RIP**, under **Advanced Options**, or use the CLI.

The CLI commands associated with garbage, timeout, and update timers include:

```
config router rip
   set timeout-timer
   set update-timer
   set garbage-timer
end
```

Update timer

The update timer determines the interval between routing updates. Generally, this value is set to 30 seconds. There is some randomness added to help prevent network traffic congestion, which could result from all routers simultaneously attempting to update their neighbors. The update timer should be at least three times smaller than the timeout timer, otherwise you will experience an error.

If you are experiencing significant RIP traffic on your network, you can increase this interval to send fewer updates per minute. However, ensure you increase the interval for all the routers on your network or you will experience time outs that will degrade your network speed.

Timeout timer

The timeout timer is the maximum amount of time (in seconds) that a route is considered reachable while no updates are received for the route. This is the maximum time the FortiGate unit will keep a reachable route in the routing table while no updates for that route are received. If the FortiGate unit receives an update for the route before the timeout period expires, the timer is restarted. The timeout period should be at least three times longer than the depute period, otherwise you will experience an error.

If you are experiencing problems with routers not responding in time to updates, increase this timer. However, remember that longer timeout intervals result in longer overall update periods — it may be considerable time before the time the FortiGate unit is done waiting for all the timers to expire on unresponsive routes.

Garbage timer

The garbage timer is the amount of time (in seconds) that the FortiGate unit will advertise a route as being unreachable before deleting the route from the routing table. If this timer is shorter, it will keep more up-to-date routes in the routing table and remove old ones faster. This will result in a smaller routing table which is useful if you have a very large network, or if your network changes frequently.

Authentication and key-chain

RIP version 2 uses authentication keys to ensure that the routing information exchanged between routers is reliable. RIP version 1 has no authentication. For authentication to work both the sending and receiving routers must be set to use authentication, and must be configured with the same keys.

The sending and receiving routers need to have their system dates and times synchronized to ensure both ends are using the same keys at the proper times. However, you can overlap the key lifetimes to ensure that a key is always available even if there is some difference in the system times.

A key chain is a list of one or more authentication keys including the send and receive lifetimes for each key. Keys are used for authenticating routing packets only during the specified lifetimes. The FortiGate unit migrates from one key to the next according to the scheduled send and receive lifetimes.

Key-chain is a CLI router command. You use this command to manage RIP version 2 authentication keys. You can add, edit or delete keys identified by the specified key number.

This example shows how to configure a key-chain with two keys that are valid sequentially in time. This example creates a key-chain called “rip_key” that has a password of “fortinet”. The accepted and send lifetimes are both set to the same values — a start time of 9:00am February 23, 2010 and an end time of 9:00am March 17, 2010. A second key is configured with a password of “my_fortigate” that is valid from March 17, 2010 9:01am to April 1 2010 9:00am. This “rip_key” keychain is then used on the port1 interface in RIP.

```
config router key-chain
   edit "rip_key"
      config key
      edit 1
         set accept-lifetime 09:00:00 23 02 2010 09:00:00 17 03 2010
         set key-string "fortinet"
         set send-lifetime 09:00:00 23 02 2010 09:00:00 17 03 2010
      next
      edit 2
```

```
      set accept-lifetime 09:01:00 17 03 2010 09:00:00 1 04 2010
      set key-string "my_fortigate"
      set send-lifetime 09:01:00 17 03 2010 09:00:00 1 04 2010
    next
    end
  end
config router rip
  config interface
    edit port1
      set auth-keychain "rip_key"
    end
  end
```

The CLI commands associated with authentication keys include:

```
config router key-chain

config router rip
  config interface
    edit <interface>
      set auth-keychain
      set auth-mode
      set auth-string
    end
  end
```

Access Lists

Access lists are filters used by FortiGate unit RIP and OSPF routing. An access list provides a list of IP addresses and the action to take for them — essentially an access list makes it easy to group addresses that will be treated the same into the same group, independent of their subnets or other matching qualities. You add a rule for each address or subnet that you want to include, specifying the action to take for it. For example if you wanted all traffic from one department to be routed a particular way, even in different buildings, you can add all the addresses to an access list and then handle that list all at once.

Each rule in an access list consists of a prefix (IP address and netmask), the action to take for this prefix (permit or deny), and whether to match the prefix exactly or to match the prefix and any more specific prefix.

The FortiGate unit attempts to match a packet against the rules in an access list starting at the top of the list. If it finds a match for the prefix, it takes the action specified for that prefix. If no match is found the default action is deny.

Access lists greatly speed up configuration and network management. When there is a problem, you can check each list instead of individual addresses. Also its easier to troubleshoot since if all addresses on one list have problems, it eliminates many possible causes right away.

If you are using the RIPng or OSPF+ IPv6 protocols you will need to use access-list6, the IPv6 version of access list. The only difference is that access-list6 uses IPv6 addresses.

For example, if you want to create an access list called `test_list` that only allows an exact match of `10.10.10.10` and `11.11.11.11`, enter the command:

```
config router access-list
  edit test_list
    config rule
      edit 1
        set prefix 10.10.10.10 255.255.255.255
        set action allow
```

```
            set exact-match enable
         next
         edit 2
            set prefix 11.11.11.11 255.255.255.255
            set action allow
            set exact-match enable
         end
      end
```

Another example is if you want to deny ranges of addresses in IPv6 that start with the IPv6 equivalents of 10.10.10.10 and 11.11.11.11, enter the command access-list6 as follows:

```
config router access-list6
   edit test_list_ip6
      config rule
         edit 1
            set prefix6 2002:A0A:A0A:0:0:0:0:0:/48
            set action deny
         next
         edit 2
            set prefix6 2002:B0B:B0B:0:0:0:0:0/48
            set action deny
         end
      end
```

To use an access_list, you must call it from a routing protocol such as RIP. The following example uses the access_list from the earlier example called test_list to match routes coming in on the port1 interface. When there is a match, it will add 3 to the hop count metric for those routes to artificially increase . Enter the following command:

```
config router rip
   config offset-list
      edit 5
         set access-list test_list
         set direction in
         set interface port1
         set offset 3
         set status enable
      end
```

If you are setting a prefix of 128.0.0.0, use the format 128.0.0.0/1. The default route, 0.0.0.0/0 can not be exactly matched with an access-list. A prefix-list must be used for this purpose

How RIP works

As one of the original modern dynamic routing protocols, RIP is straightforward. Its routing algorithm is not complex, there are some options to allow fine tuning, and it's relatively simple to configure RIP on FortiGate units.

From RFC 1058:

> *Distance vector algorithms are based on the exchange of only a small amount of information. Each entity (gateway or host) that participates in the routing protocol is assumed to keep information about all of the destinations within the system. Generally, information about all entities connected to one network is summarized by a single entry, which describes the route to all destinations on that network.*

This section includes:

- RIP versus static routing
- RIP metric — hop count
- The Bellman–Ford routing algorithm
- Passive versus active RIP interfaces
- RIP packet structure

RIP versus static routing

RIP was one of the earliest dynamic routing protocols to work with IP addresses. As such, it is not as complex as more recent protocols. However, RIP is a big step forward from simple static routing.

While RIP may be slow in response to network outages, static routing has zero response. The same is true for convergence — static routing has zero convergence. Both RIP and static routing have the limited hop count, so its not a strength or a weakness. Count to infinity can be a problem, but typically can be fixed as it happens or is the result of a network outage that would cause even worse problems on static routing network.

This compares to static routing where each time a packet needs to be routed, the FortiGate unit can only send it to the next hop towards the destination. That next hop then forwards it, and so on until it arrives at its destination. RIP keeps more routing information on each router so your FortiGate unit can send the packet farther towards its destination before it has to be routed again towards its destination. RIP reduces the amount of table lookups and therefore fewer network resources than static routing. Also since RIP is updated on neighboring routes it is aware of new routes or dead routes that static routing would not be aware of.

Overall, RIP is a large step forward when compared to static routing.

RIP metric — hop count

RIP uses hop count as the metric for choosing the best route. A hop count of 1 represents a network that is connected directly to the FortiGate unit, while a hop count of 16 represents a network that cannot be reached. Each network that a packet travels through to reach its destination usually counts as one hop. When the FortiGate unit compares two routes to the same destination, it adds the route having the lowest hop count to the routing table. As you can see in RIP packet structure on page 399, the hop count is part of a RIP v2 packet.

Similarly, when RIP is enabled on an interface, the FortiGate unit sends RIP responses to neighboring routers on a regular basis. The updates provide information about the routes in the FortiGate unit's routing table, subject to the rules that you specify for advertising those routes. You can specify how often the FortiGate unit sends updates, the period of time a route can be kept in the routing table without being updated, and for routes that are not updated regularly you can specify the period of time that the unit advertises a route as unreachable before it is removed from the routing table.

If hops are weighted higher than one, it becomes very easy to reach the upper limit. This higher weighting will effectively limit the size of your network depending on the numbers used. Merely changing from the default of 1.0 to 1.5 will lower the effective hop count from 15 to 10. This is acceptable for smaller networks, but can be a problem as your network expands over time.

In RIP, you can use the offset command to artificially increase the hop count of a route. Doing this will make this route less preferred, and in turn it will get less traffic. Offsetting routes is useful when you have network connections of different bandwidths, different levels of reliability, or different costs. In each of these situations you still want the redundancy of multiple route access, but you don't want the bulk of your traffic using these less preferred routes. For an example of RIP offset, see Access Lists on page 393.

The Bellman–Ford routing algorithm

The routing algorithm used by RIP was first used in 1967 as the initial routing algorithm of the ARPANET. The Bellman–Ford algorithm is distributed because it involves a number of nodes (routers) within an Autonomous system, and consists of the following steps:

1. Each node calculates the distances between itself and all other nodes within the AS and stores this information as a table.
2. Each node sends its table to all neighboring nodes.
3. When a node receives distance tables from its neighbors, it calculates the shortest routes to all other nodes and updates its own table to reflect any changes.

To examine how this algorithm functions let's look at a network with 4 routers — routers 1 through 4. The distance from router1 to router2 is 2 hops, 1 to 3 is 3 hops, and 2 to 3 is 4 hops. Router4 is only connected to routers 2 and 3, each distance being 2 hops.

1. Router1 finds all the distance to the other three routers — router 2 is 2, router 3 is 3. Router1 doesn't have a route to router 4.
2. Routers 2 through 4 do the same calculations from their point of views.
3. Once router 1 gets an update from router 2 or 3, it will get their route to router 4. At that point it now has a route to router 4 and installs that in its local table.
4. If router1 gets an update from router3 first, it has a hop count of 5 to reach router4. But when router2 sends its update, router1 will go with router2's shorter 4 hops to reach router4. Future updates don't change this unless they are shorter than 4 hops, or the routing table route goes down.

RIP algorithm example in 4 steps

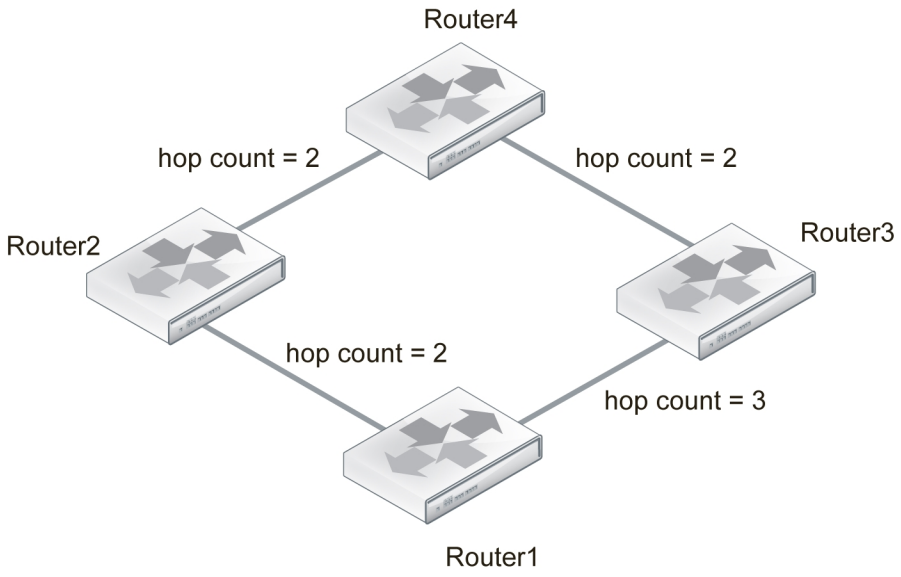
Step 1

Router1 finds the distance to other routers in the network.

It currently has no route to Router4.

Router1 routing table:

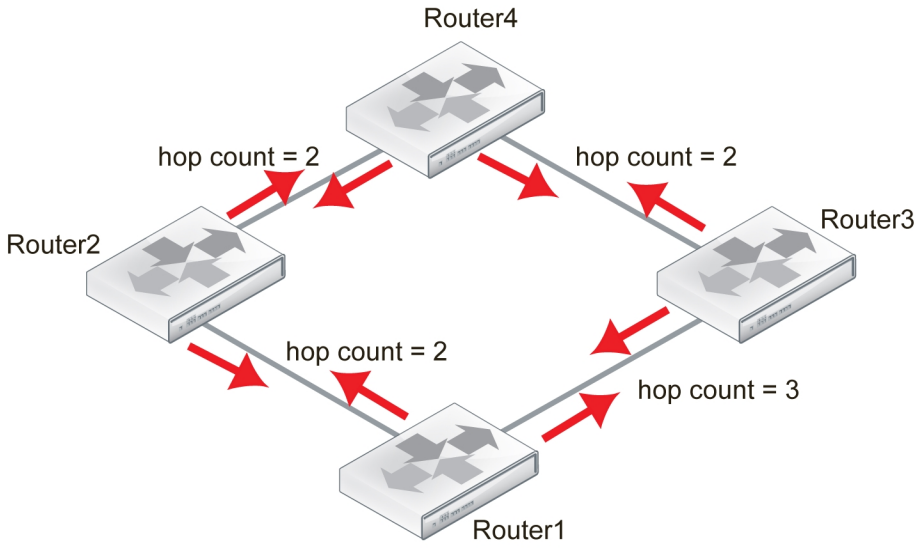
- Distance to Router2 = 2 hops.
- Distance to Router3 = 3 hops.



Step 2

All routers do the same as Router1, and send out updates containing their routing table.

Note that Router1 and Router4 do not update each other, but rely on Router2 and Router3 to pass along accurate updates.

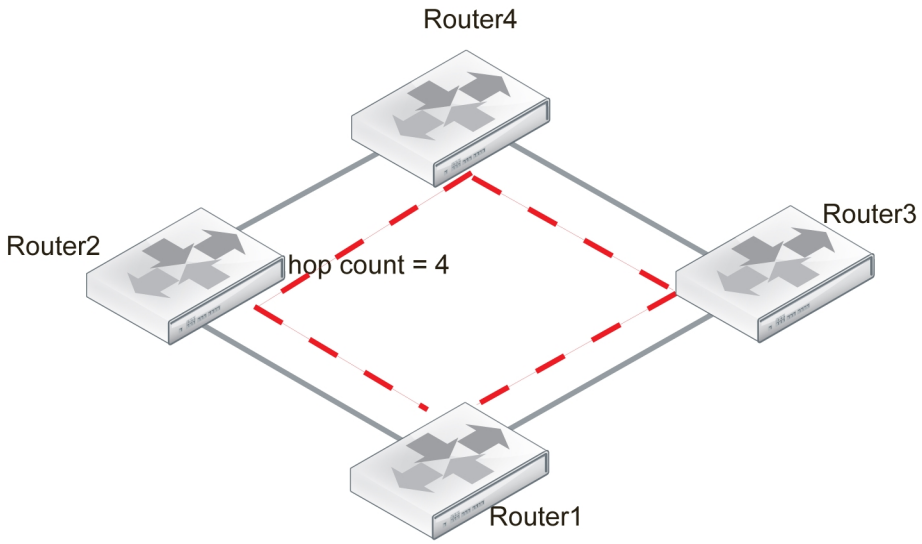


Step 3

Each router looks at the updates it has received, and adds any new or shorter routes to its table.

Router1 updated table:

- Distance to Router2 = 2 hops.
- Distance to Router3 = 3 hops.
- Distance to Router4 = 4 or 5 hops.

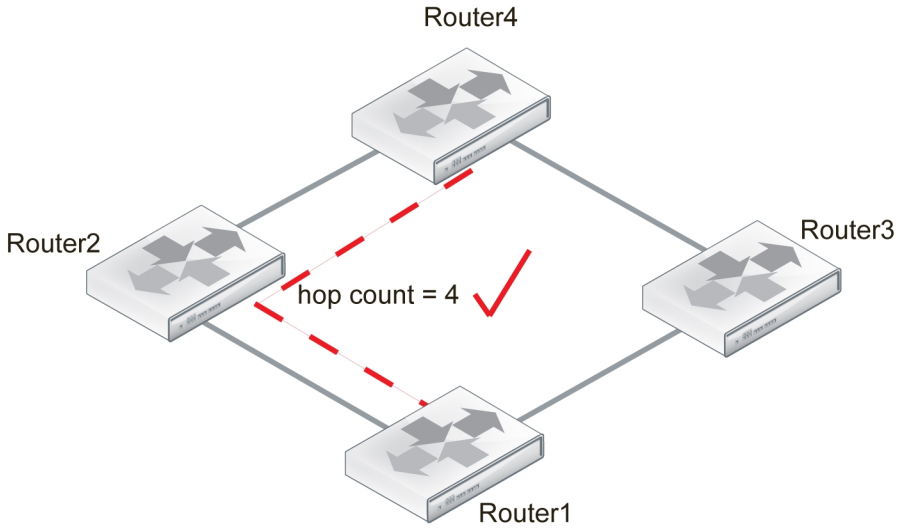


Step 4

Router1 installs the shortest route to Router4, and the other routes to it are removed from the routing table.

Router1 complete table:

- Distance to Router2 = 2 hops.
- Distance to Router3 = 3 hops.
- Distance to Router4 = 4 hops.



The good part about the Bellman-Ford algorithm in RIP is that the router only uses the information it needs from the update. If there are no newer, better routes than the ones the router already has in its routing table, there is no need to change its routing table. And no change means no additional update, so less traffic. But even when there is update traffic, the RIP packets are very small so it takes many updates to affect overall network bandwidth. For more information about RIP packets, see RIP packet structure on page 399.

The main disadvantage of the Bellman–Ford algorithm in RIP is that it doesn't take weightings into consideration. While it is possible to assign different weights to routes in RIP, doing so severely limits the effective network size

by reducing the hop count limit. Also other dynamic routing protocols can take route qualities, such as reliability or delay, into consideration to provide not only the physically shortest but also the fastest or more reliable routes as you choose.

Another disadvantage of the Bellman-Ford algorithm is due to the slow updates passed from one RIP router to the next. This results in a slow response to changes in the network topology, which in turn results in more attempts to use routes that are down, which wastes time and network resources.

Passive versus active RIP interfaces

Normally the FortiGate unit's routing table is kept up to date by periodically asking the neighbors for routes, and sending your routing updates out. This has the downside of generating a lot of extra traffic for large networks. The solution to this problem is passive interfaces.

An standard interface that supports RIP is active by default — it both sends and receives updates by actively communicating with its neighbors. A passive RIP interface does not send out updates — it just listens to the updates of other routers. This is useful in reducing network traffic, and if there are redundant routers in the network that would be sending out essentially the same updates all the time.

The following example shows how to create a passive RIP v2 interface on port1, using MD5 authentication and a key-chain called `passiveRIPv2` that has already been configured. Note that in the CLI, you enable passive by disabling `send-version2-broadcast`.

To create a passive RIP interface - web-based manager

1. Go to **Network > RIP**.
2. Next to **Interfaces**, select **Create**.
3. Select port1 as the **Interface**.
4. Select 2 as both the **Send Version** and **Receive Version**.
5. Select MD5 for **Authentication**.
6. Select the `passiveRIPv2` **Key-chain**.
7. Select **Passive Interface**.
8. Select **OK** to accept this configuration, and return to the main RIP display page.

To create a passive RIP v2 interface on port1 using MD5 authentication- CLI

```
config router rip
   config interface
      edit port1
         set send-version2-broadcast disable
         set auth-keychain "passiveRIPv2"
         set auth-mode md5
         set receive-version 2
         set send-version 2
      end
   end
```

RIP packet structure

It is hard to fully understand a routing protocol without knowing what information is carried in its packets. Knowing what information is exchanged between routers and how will help you better understand the RIP protocol, and better configure your network for it.

This section provides information on the contents of RIP 1 and RIP 2 packets.

RIP version 1

RIP version 1, or RIP IP packets are 24 bytes in length, with some empty areas left for future expansion.

RIP IP packets

1-byte command	1-byte version	2-byte zero field	2-byte AFI	2-byte zero field
4-byte IP address	4-byte zero field	4-byte zero field	4-byte metric	

A RIP 1 packet contains the following fields:

- **Command** — Indicates whether the packet is a request or a response. The request asks that a router send all or part of its routing table. The response can be an unsolicited regular routing update or a reply to a request. Responses contain routing table entries. Multiple RIP packets are used to convey information from large routing tables.
- **Version** — Specifies the RIP version used. This field can signal different potentially incompatible versions.
- **Zero field** — This field defaults to zero, and is not used by RFC 1058 RIP.
- **Address-family identifier (AFI)** — Specifies the address family used. RIP is designed to carry routing information for several different protocols. Each entry has an address-family identifier to indicate the type of address being specified. The AFI for IP is 2.
- **IP Address** — Specifies the IP address for the entry.
- **Metric** — This is the number of hops or routers traversed along the route on its trip to the destination. The metric is between 1 and 15 for that number of hops. If the route is unreachable the metric is 16.

RIP version 2

RIP version 2 has more features than RIP 1, which is reflected in its packets which carry more information. All but one of the empty zero fields in RIP 1 packets are used in RIP 2.

RIP 2 packets

1-byte command	1-byte version	2-byte unused	2-byte AFI	2-byte route tag
4-byte IP address	4-byte subnet	4-byte next hop	4-byte metric	

A RIP 2 packet contains fields described above in RIP 1, as well as the following:

- **Unused** — Has a value set to zero, and is intended for future use
- **Route tag** — Provides a method for distinguishing between internal routes learned by RIP and external routes learned from other protocols.
- **Subnet mask** — Contains the subnet mask for the entry. If this field is zero, no subnet mask has been specified for the entry.
- **Next hop** — Indicates the IP address of the next hop to which packets for the entry should be forwarded.

Troubleshooting RIP

This section is about troubleshooting RIP. For general troubleshooting information, see the FortiOS Handbook Troubleshooting chapter.

This section includes:

- Routing Loops
- Holddowns and Triggers for updates
- Split horizon and Poison reverse updates
- Debugging IPv6 on RIPng

Routing Loops

Normally in routing, a path between two addresses is chosen and traffic is routed along that path from one address to the other. When there is a routing loop, that normal path doubles back on itself creating a loop. When there are loops, the network has problems getting information to its destination and also prevents it from returning to the source to report the inaccessible destination.

A routing loop happens when a normally functioning network has an outage, and one or more routers are offline. When packets encounter this, an alternate route is attempted to maneuver around the outage. During this phase it is possible for a route to be attempted that involves going back a hop, and trying a different hop forward. If that hop forward is blocked by the outage as well, a hop back and possibly the original hop forward may be selected. You can see if this continues, how it can consume not only network bandwidth but also many resources on those routers affected. The worst part is this situation will continue until the network administrator changes the router settings, or the downed routers come back online.

Routing loops' effect on the network

In addition to this "traffic jam" of routed packets, every time the routing table for a router changes that router sends an update out to all of the RIP routers connected to it. In a network loop, its possible for a router to change its routes very quickly as it tries and fails along these new routes. This can quickly result in a flood of updates being sent out, which can effectively grind the network to a halt until the problem is fixed.

How can you spot a routing loop

Any time network traffic slows down, you will be asking yourself if it is a network loop or not. Often slowdowns are normal, they are not a full stoppage, and normal traffic resumes in a short period of time.

If the slow down is a full halt of traffic or a major slowdown does not return to normal quickly, you need to do serious troubleshooting quickly.

If you aren't running SNMP, dead gateway detection, or you have non-Fortinet routers in your network, you can use networking tools such as ping and traceroute to define the outage on your network and begin to fix it. Ping, traceroute, and other basic troubleshooting tools are largely the same between static and dynamic, and are covered in Advanced Static Routing on page 2343.

Check your logs

If your routers log events to a central location, it can be easy to check the logs for your network for any outages.

On your FortiGate unit, go to **Log & Report**. You will want to look at both event logs and traffic logs. Events to look for will generally fall under CPU and memory usage, interfaces going offline (due to dead gateway detection), and other similar system events.

Once you have found and fixed your network problem, you can go back to the logs and create a report to better see how things developed during the problem. This type of forensics analysis can better help you prepare for next time.

Use SNMP network monitoring

If your network had no problems one minute and slows to a halt the next, chances are something changed to cause that problem. Most of the time an offline router is the cause, and once you find that router and bring it back online, things will return to normal.

If you can enable a hardware monitoring system such as SNMP or sFlow on your routers, you can be notified of the outage and where it is exactly as soon as it happens.

Ideally you can configure SNMP on all your FortiGate routers and be alerted to all outages as they occur.

To use SNMP to detect potential routing loops

1. Go to **System > SNMP**.
2. Enable **SMTP Agent** and select **Apply**.
   Optionally enter the **Description**, **Location**, and **Contact** information for this device for easier location of the problem report.
3. Under **SNMP v1/v2** or **SNMP v3** as appropriate, select **Create New**.
   SNMP v3

User Name	Enter the SNMP user ID.
Security Level	Select authentication or privacy as desired. Select the authentication or privacy algorithms to use and enter the required passwords.
Notification Host	Enter the IP addresses of up to 16 hosts to notify.
Enable Query	Select. The **Port** should be 161. Ensure that your security policies allow ports 161 and 162 (SNMP queries and traps) to pass.

   SNMP v1/v2

Hosts	Enter the IP addresses of up to 8 hosts to notify. You can also specify the network **Interface**, or leave it as **ANY**.
Queries	Enable **v1** and/or **v2** as needed. The **Port** should be 161. Ensure that your security policies allow port 161 to pass.
Traps	Enable v1 and/or v2 as needed. The Port should be 162. Ensure that your security policies allow port 162 to pass.

4. Select the events for which you want notification. For routing loops this should include **CPU usage is high**, **Memory is low**, and possibly **Log disk space is low**.If there are problems the log will be filling up quickly, and the FortiGate unit's resources will be overused.

5. Configure SNMP host (manager) software on your administration computer. This will monitor the SNMP information sent out by the FortiGate unit. Typically you can configure this software to alert you to outages or CPU spikes that may indicate a routing loop.

Use Link Health Monitor and e-mail alerts

Another tool available to you on FortiGate units is the Link Health Monitor, useful in dead gateway detection. This feature allows the FortiGate unit to ping a gateway at regular intervals to ensure it is online and working. When the gateway is not accessible, that interface is marked as down.

To detect possible routing loops with Link Health Monitor and e-mail alerts

Use the following command to configure dead gateway detection:

```
config system link-monitor
   edit "test"
      set srcintf "internal4"
      set server "8.8.8.8"
      set interval 5
      set failtime 1
   end
```

Set the `Interval` (how often to send a ping) and `failtime` (how many lost pings is considered a failure). A smaller interval and smaller number of lost pings will result in faster detection, but will create more traffic on your network.

To configure notification of failed gateways

1. Go to **Log & Report > Local Report**and enable **Email Generated Reports**.
2. Enter your email details.
3. Select **Apply**.

You might also want to log CPU and Memory usage as a network outage will cause your CPU activity to spike.

If you have VDOMs configured, you will have to enter the basic SMTP server information in the Global section, and the rest of the configuration within the VDOM that includes this interface.

After this configuration, when this interface on the FortiGate unit cannot connect to the next router, the FortiGate unit will bring down the interface and alert you with an email about the outage.

Look at the packet flow

If you want to see what is happening on your network, look at the packets travelling on the network. This is same idea as police pulling over a car and asking the driver where they have been, and what the conditions were like.

The method used in the troubleshooting sections Debugging IPv6 on RIPng on page 405 and on debugging the packet flow apply here as well. In this situation, you are looking for routes that have metrics higher than 15 as that indicates they are unreachable.

Ideally if you debug the flow of the packets, and record the routes that are unreachable, you can create an accurate picture of the network outage.

Action to take on discovering a routing loop

Once you have mapped the problem on your network, and determined it is in fact a routing loop there are a number of steps to take in correcting it.

1. Get any offline routers back online. This may be a simple reboot, or you may have to replace hardware. Often this first step will restore your network to its normal operation, once the routing tables finish being updated.
2. Change your routing configuration on the edges of the outage. Even if step 1 brought your network back online, you should consider making changes to improve your network before the next outage occurs. These changes can include configuring features like holddowns and triggers for updates, split horizon, and poison reverse updates.

Holddowns and Triggers for updates

One of the potential problems with RIP is the frequent routing table updates that are sent every time there is a change to the routing table. If your network has many RIP routers, these updates can start to slow down your network. Also if you have a particular route that has bad hardware, it might be going up and down frequently, which will generate an overload of routing table updates.

One of the most common solutions to this problem is to use holddown timers and triggers for updates. These slow down the updates that are sent out, and help prevent a potential flood.

Holddown Timers

The holddown timer activates when a route is marked down. Until the timer expires, the router does not accept any new information about that route. This is very useful if you have a flapping route because it will prevent your router from sending out updates and being part of the problem in flooding the network. The potential down side is if the route comes back up while the timer has not expired, that route will be unavailable for that period of time. This is only a problem if this is a major route used by the majority of your traffic. Otherwise, this is a minor problem as traffic can be re-routed around the outage.

Triggers

Triggered RIP is an alternate update structure that is based around limiting updates to only specific circumstances. The most basic difference is that the routing table will only be updated when a specific request is sent to update, as opposed to every time the routing table changes. Updates are also triggered when a unit is ‘powered on’, which can include addition of new interfaces or devices to the routing structure, or devices returning to being available after being unreachable.

Split horizon and Poison reverse updates

Split horizon is best explained with an example. You have three routers linked serially, let’s call them A, B, and C. A is only linked to B, C is only linked to B, and B is linked to both A and C. To get to C, A must go through B. If the link to C goes down, it is possible that B will try to use A’s route to get to C. This route is A-B-C, so it will loop endlessly between A and B.

This situation is called a split horizon because from B’s point of view the horizon stretches out in each direction, but in reality it only is on one side.

Poison reverse is the method used to prevent routes from running into split horizon problems. Poison reverse “poisons” routes away from the destination that use the current router in their route to the destination. This “poisoned” route is marked as unreachable for routers that cannot use it. In RIP this means that route is marked with a distance of 16.

Debugging IPv6 on RIPng

The debug commands are very useful to see what is happening on the network at the packet level. There are a few changes to debugging the packet flow when debugging IPv6.

The following CLI commands specify both IPv6 and RIP, so only RIPng packets will be reported. The output from these commands will show you the RIPng traffic on your FortiGate unit including RECV, SEND, and UPDATE actions.

The addresses are in IPv6 format.

```
diagnose debug enable
diagnose ipv6 router rip level info
diagnose ipv6 router rip all enable
```

These three commands will:

- turn on debugging in general
- set the debug level to information, a verbose reporting level
- turn on all rip router settings

Part of the information displayed from the debugging is the metric (hop count). If the metric is 16, then that destination is unreachable since the maximum hop count is 15.

In general, you should see an update announcement, followed by the routing table being sent out, and a received reply in response.

For more information, see Troubleshooting RIP on page 401.

Simple RIP example

This is an example of a typical medium sized network configuration using RIP routing.

Your company has 3 small local networks, one for each department. These networks are connected by RIP, and then connected to the Internet. Each subnet has more than one route, for redundancy. There are two central routers that are both connected to the Internet, and to the other networks. If one of those routers goes down, the whole network can continue to function normally.

The ISP is running RIP, so no importing or exporting routes is required on the side of the network. However, since the internal networks have static networking running those will need to be redistributed through the RIP network.

To keep the example simple, there will be no authentication of router traffic.

With RIP properly configured, if the device fails or temporarily goes offline, the routes will change and traffic will continue to flow. RIP is good for a smaller network due to its lack of complex configurations.

This section includes the following topics:

- Network layout and assumptions
- General configuration steps
- Configuring the FortiGate units system information
- Configuring other networking devices
- Testing network configuration

Network layout and assumptions

Basic network layout

Your company has 3 departments each with their own network — Sales, R&D, and Accounting. Each network has routers that are not running RIP as well as FortiGate units running RIP.

The R&D network has two RIP routers, and each is connected to both other departments as well as being connected to the Internet through the ISP router. The links to the Internet are indicated in black.

The three internal networks do not run RIP. They use static routing because they are small networks. This means the FortiGate units have to redistribute any static routes they learn so that the internal networks can communicate with each other.

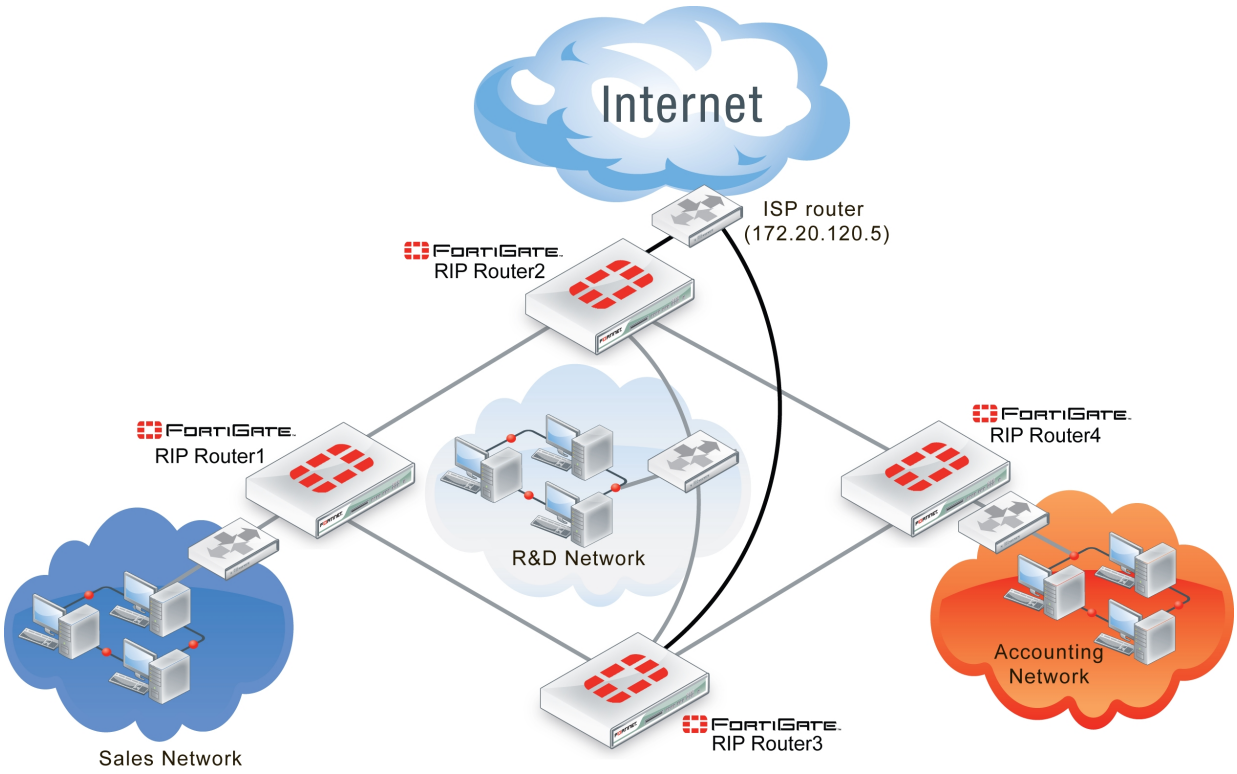
Where possible in this example, the default values will be used or the most general settings. This is intended to provide an easier configuration that will require less troubleshooting.

In this example the routers, networks, interfaces used, and IP addresses are as follows. Note that the Interfaces that connect Router2 and Router3 also connect to the R&D network.

RIP example network topology

Network	Router	Interface & Alias	IP address
Sales	Router1	port1 (internal)	10.11.101.101
		port2 (router2)	10.11.201.101
		port3 (router3)	10.11.202.101
R&D	Router2	port1 (internal)	10.12.101.102
		port2 (router1)	10.11.201.102
		port3 (router4)	10.14.201.102
		port4 (ISP)	172.20.120.102
	Router3	port1 (internal)	10.12.101.103
		port2 (router1)	10.11.201.103
		port3 (router4)	10.14.202.103
		port4 (ISP)	172.20.120.103
Accounting	Router4	port1 (internal)	10.14.101.104
		port2 (router2)	10.14.201.104
		port3 (router3)	10.14.202.104

Network topology for the simple RIP example



Assumptions

The following assumptions have been made concerning this example.

- All FortiGate units have 5.0 firmware, and are running factory default settings.
- All CLI and web-based manager navigation assumes the unit is running in NAT/Route operating mode, with VDOMs disabled.
- All FortiGate units have interfaces labelled port1 through port4 as required.
- All firewalls have been configured for each FortiGate unit to allow the required traffic to flow across interfaces.
- Only FortiGate units are running RIP on the internal networks.
- Router2 and Router3 are connected through the internal network for R&D.
- Router2 and Router3 each have their own connection to the Internet, indicated in black in the diagram above.

General configuration steps

This example is very straight forward. The only steps involved are:

- Configuring the FortiGate units system information
- Configuring FortiGate unit RIP router information
- Configuring other networking devices
- Testing network configuration

Configuring the FortiGate units system information

Each FortiGate unit needs their hostname, and interfaces configured.

For IP numbering, Router2 and Router3 use the other routers numbering where needed.

Router2 and Router3 have dead gateway detection enabled on the ISP interfaces using Ping. Remember to contact the ISP and confirm their server has ping enabled.

Configure the hostname, interfaces, and default route

To configure Router1 system information - web-based manager

1. Go to **Dashboard > System Information**.
2. Next to **Host Name** select **Change**, and enter “Router1”.
3. Go to **Network > Static Routes**.
4. Edit the default route and enter the following information:

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port2 (router2)
Gateway	172.20.120.5/255.255.255.0
Distance	40

5. Enter a second default route and enter the following information:

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port3 (router3)
Gateway	172.20.120.5/255.255.255.0
Distance	40

6. Go to **Network > Interfaces**.
7. Edit port1 (internal) interface.
8. Set the following information, and select **OK**.

Alias	internal
IP/Network Mask	10.11.101.101/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Internal sales network
Administrative Status	Up

9. Edit port2 (router2) interface.
10. Set the following information, and select **OK**.

Alias	router2

IP/Network Mask	10.11.201.101/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Link to R&D network & Internet through Router2
Administrative Status	Up

11. Edit port3 (router3) interface.
12. Set the following information, and select **OK**.

Alias	router3
IP/Network Mask	10.11.202.101/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Link to R&D network and Internet through Router3
Administrative Status	Up

To configure Router1 system information - CLI

```
config system global
   set hostname Router1
end

config router static
   edit 1
      set device "port2"
      set distance 45
      set gateway 10.11.201.102
   next
   edit 2
      set device "port3"
      set distance 45
      set gateway 10.11.202.103
   end
end

config system interface
   edit port1
      set alias internal
      set ip 10.11.101.101/255.255.255.0
      set allowaccess https ssh ping
      set description "Internal sales network"
   next
   edit port2
      set alias ISP
      set allowaccess https ssh ping
      set ip 10.11.201.101/255.255.255.0
      set description "Link to R&D network & Internet through Router2"
   next
   edit port3
      set alias router3
```

```
        set ip 10.11.202.101/255.255.255.0
        set allowaccess https ssh ping
        set description "Link to R&D network & Internet through Router2"
    end
end
```

To configure Router2 system information - web-based manager

1. Go to **Dashboard > System Information**.
2. Next to **Host Name** select **Change**, and enter “Router2”.
3. Go to **Network > Static Routes**.
4. Edit the default route and enter the following information:

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port4 (ISP)
Gateway	172.20.120.5/255.255.255.0
Distance	5

5. Go to **Network > Interfaces**.
6. Edit port1 (internal) interface.
7. Set the following information, and select **OK**.

Alias	internal
IP/Network Mask	10.12.101.102/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	R&D internal network and Router3
Administrative Status	Up

8. Edit port2 (router1) interface.
9. Set the following information, and select **OK**.

Alias	router1
IP/Network Mask	10.12.201.102/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Link to Router1 and the Sales network
Administrative Status	Up

10. Edit port3 (router4) interface.
11. Set the following information, and select **OK**.

Alias	router4
IP/Network Mask	10.12.301.102/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Link to Router4 and the accounting network
Administrative Status	Up

12. Edit port4 (ISP) interface.
13. Set the following information, and select **OK**.

Alias	ISP
IP/Network Mask	172.20.120.102/255.255.255.0
Administrative Access	HTTPS SSH PING
Detect and Identify Devices	enable
Description	Internet through ISP
Administrative Status	Up

To configure Router2 system information - CLI

```
config system global
   set hostname Router2
end
config router static
   edit 1
      set device "port4"
      set distance 5
      set gateway 172.20.130.5
   end
end
config system interface
   edit port1
      set alias internal
      set ip 10.11.101.102/255.255.255.0
      set allowaccess https ssh ping
      set description "Internal RnD network and Router3"
   next
   edit port2
      set alias router1
      set allowaccess https ssh ping
      set ip 10.11.201.102/255.255.255.0
      set description "Link to Router1"
   next
   edit port3
      set alias router3
      set ip 10.14.202.102/255.255.255.0
      set allowaccess https ssh ping
      set description "Link to Router4"
   next
```

```
    edit port4
       set alias ISP
       set ip 172.20.120.102/255.255.255.0
       set allowaccess https ssh ping
       set description "ISP and Internet"
    end
end
```

To configure Router3 system information - web-based manager

1. Go to **Dashboard > System Information**.
2. Next to **Host Name** select **Change**, and enter “Router3”.
3. Go to **Network > Static Routes**.
4. Edit the default route and enter the following information:

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port4 (ISP)
Gateway	172.20.120.5/255.255.255.0
Distance	5

5. Go to **System > Network > Interfaces**.
6. Edit port1 (internal) interface.
7. Set the following information, and select **OK**.

Alias	internal
IP/Network Mask	10.12.101.103/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	R&D internal network and Router2
Administrative Status	Up

8. Edit port2 (router1) interface.
9. Set the following information, and select **OK**.

Alias	router1
IP/Network Mask	10.13.201.103/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Link to Router1 and Sales network
Administrative Status	Up

10. Edit port3 (router4) interface.
11. Set the following information, and select **OK**.

Alias	router4
IP/Network Mask	10.13.301.103/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Link to Router4 and accounting network
Administrative Status	Up

12. Edit port4 (ISP) interface.
13. Set the following information, and select **OK**.

Alias	ISP
IP/Network Mask	172.20.120.103/255.255.255.0
Administrative Access	HTTPS SSH PING
Detect and Identify Devices	enable
Description	Internet and ISP
Administrative Status	Up

To configure Router3 system information - CLI

```
config system global
   set hostname Router3
end
config router static
   edit 1
      set device "port4"
      set distance 5
      set gateway 172.20.130.5
   end
end
config system interface
   edit port1
      set alias internal
      set ip 10.12.101.103/255.255.255.0
      set allowaccess https ssh ping
      set description “Internal RnD network and Router2”
   next
   edit port2
      set alias ISP
      set allowaccess https ssh ping
      set ip 10.11.201.103/255.255.255.0
      set description “Link to Router1”
   next
   edit port3
      set alias router3
      set ip 10.14.202.103/255.255.255.0
      set allowaccess https ssh ping
      set description “Link to Router4”
   next
```

```
    edit port4
       set alias ISP
       set ip 172.20.120.103/255.255.255.0
       set allowaccess https ssh ping
       set description "ISP and Internet"
    end
end
```

To configure Router4 system information - web-based manager

1. Go to **Dashboard > System Information**.
2. Next to **Host Name** select **Change**, and enter "Router4".
3. Go to **Network > Static Routes**.
4. Edit the default route and enter the following information:

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port2 (router2)
Gateway	172.20.120.5/255.255.255.0
Distance	40

5. Enter a second default route and enter the following information:

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port3 (router3)
Gateway	172.20.120.5/255.255.255.0
Distance	40

6. Go to **Network > Interfaces**.
7. Edit port 1 (internal) interface.
8. Set the following information, and select **OK**.

Alias	internal
IP/Network Mask	10.14.101.104/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Internal accounting network
Administrative Status	Up

9. Edit port 2 (router2) interface.
10. Set the following information, and select **OK**.

Alias	router2

IP/Network Mask	10.14.201.104/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Link to R&D network & Internet through Router2
Administrative Status	Up

11. Edit port 3 (router3) interface.
12. Set the following information, and select **OK**.

Alias	router3
IP/Network Mask	10.14.301.104/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Link to R&D network and Internet through Router3
Administrative Status	Up

To configure Router4 system information - CLI

```
config system global
   set hostname Router4
end
config router static
   edit 1
      set device "port2"
      set distance 45
      set gateway 10.14.201.102
   next
   edit 2
      set device "port3"
      set distance 45
      set gateway 10.14.202.103
   end
end
config system interface
   edit port1
      set alias internal
      set ip 10.14.101.104/255.255.255.0
      set allowaccess https ssh ping
      set description "Internal sales network"
   next
   edit port2
      set alias router2
      set allowaccess https ssh ping
      set ip 10.14.201.104/255.255.255.0
      set description "Link to R&D network & Internet through Router2"
   next
   edit port3
      set alias router3
      set ip 10.14.202.104/255.255.255.0
      set allowaccess https ssh ping
```

```
        set description "Link to R&D network & Internet through Router2"
    end
end
```

Configuring FortiGate unit RIP router information

With the interfaces configured, RIP can now be configured on the FortiGate units.

For each FortiGate unit the following steps will be taken:

- Configure RIP version used
- Redistribute static networks
- Add networks serviced by RIP
- Add interfaces that support RIP on the FortiGate unit

Router1 and Router4 are configured the same. Router2 and Router3 are configured the same. These routers will be grouped accordingly for the following procedures — repeat the procedures once for each FortiGate unit.

Configure RIP settings on Router1 and Router4 - web-based manager

1. Go to **Network > RIP**.
2. Select **2** for **RIP Version**.
3. In **Advanced Options**, under **Redistribute** enable **Static**.
4. Leave the other Advanced Options at default values.
5. Enter the following networks, and select **Add** after each:
   - 10.11.0.0/255.255.0.0
   - 10.12.0.0/255.255.0.0
   - 10.14.0.0/255.255.0.0
   - 172.20.120.0/255.255.255.0
6. For interface, select **Create** and set the following information.

Interface	port1 (internal)
Send Version	Both
Receive Version	Both
Authentication	None
Passive Interface	disabled

7. For interface, select **Create** and set the following information.

Interface	port2 (router2)
Send Version	Both
Receive Version	Both
Authentication	None
Passive Interface	disabled

8. For interface, select **Create** and set the following information.

Interface	port3 (router3)
Send Version	Both
Receive Version	Both
Authentication	None
Passive Interface	disabled

Configure RIP settings on Router1 and Router4 - CLI

```
config router rip
   set version 2
   config interface
      edit "port1"
         set receive-version 1 2
         set send-version 1 2
      next
      edit "port2"
         set receive-version 1 2
         set send-version 1 2
      next
      edit "port3"
         set receive-version 1 2
         set send-version 1 2
      end
   config network
      edit 1
         set prefix 10.11.0.0 255.255.0.0
      next
      edit 2
         set prefix 10.12.0.0 255.255.0.0
      next
      edit 3
         set prefix 10.14.0.0 255.255.0.0
      next
      edit 4
         set prefix 172.20.120.0 255.255.255.0
      end
   config redistribute "static"
      set status enable
   end
end
```

Configure RIP settings on Router2 and Router3- web-based manager

1. Go to **Network > RIP**.
2. Select **2** for **RIP Version**.
3. In **Advanced Options**, under **Redistribute** enable **Static**.
4. Leave the other Advanced Options at default values.
5. Enter the following networks, and select **Add** after each:

- 10.11.0.0/255.255.0.0
- 10.12.0.0/255.255.0.0
- 10.14.0.0/255.255.0.0
- 172.20.120.0/255.255.255.0

6. For interface, select **Create** and set the following information.

Interface	port1 (internal)
Send Version	Both
Receive Version	Both
Authentication	None
Passive Interface	disabled

7. For interface, select **Create** and set the following information.

Interface	port2 (router1)
Send Version	Both
Receive Version	Both
Authentication	None
Passive Interface	disabled

8. For interface, select **Create** and set the following information.

Interface	port3 (router4)
Send Version	Both
Receive Version	Both
Authentication	None
Passive Interface	disabled

9. For interface, select **Create** and set the following information.

Interface	port4 (ISP)
Send Version	Both
Receive Version	Both
Authentication	None
Passive Interface	disabled

Configure RIP settings on Router2 and Router3- web-based manager

```
config router rip
   set version 2
   config interface
      edit "port1"
         set receive-version 1 2
         set send-version 1 2
      next
      edit "port2"
         set receive-version 1 2
         set send-version 1 2
      next
      edit "port3"
         set receive-version 1 2
         set send-version 1 2
      end
      edit "port4"
         set receive-version 1 2
         set send-version 1 2
      end
   config network
      edit 1
         set prefix 10.11.0.0 255.255.0.0
      next
      edit 2
         set prefix 10.12.0.0 255.255.0.0
      next
      edit 3
         set prefix 10.14.0.0 255.255.0.0
      next
      edit 4
         set prefix 172.20.120.0 255.255.255.0
      end
   config redistribute "static"
      set status enable
   end
end
```

Configuring other networking devices

In this example there are two groups of other devices on the the network — internal devices, and the ISP.

The first is the internal network devices on the Sales, R&D, and Accounting networks. This includes simple static routers, computers, printers and other network devices. Once the FortiGate units are configured, the internal static routers need to be configured using the internal network IP addresses. Otherwise there should be no configuration required.

The second group of devices is the ISP. This consists of the RIP router the FortiGate routers 2 and 3 connect to. You need to contact your ISP and ensure they have your information for your network such as the IP addresses of the connecting RIP routers, what version of RIP your network supports, and what authentication (if any) is used.

Testing network configuration

Once the network has been configured, you need to test that it works as expected.

The two series of tests you need to run are to test the internal networks can communicate with each other, and that the internal networks can reach the Internet.

Use ping, traceroute, and other networking tools to run these tests.

If you encounter problems, for troubleshooting help consult Simple RIP example on page 405.

RIPng — RIP and IPv6

RIP next generation, or RIPng, is the version of RIP that supports IPv6.

This is an example of a typical small network configuration using RIPng routing.

Your internal R&D network is working on a project for a large international telecom company that uses IPv6. For this reason, you have to run IPv6 on your internal network and you have decided to use only IPv6 addresses.

Your network has two FortiGate units running the RIPng dynamic routing protocol. Both FortiGate units are connected to the ISP router and the internal network. This configuration provides some redundancy for the R&D internal network enabling it to reach the Internet at all times.

This section includes the following topics:

- Network layout and assumptions
- Configuring the FortiGate units system information
- Configuring RIPng on FortiGate units
- Configuring other network devices
- Testing the configuration

Network layout and assumptions

Basic network layout

Your internal R&D network is working on a project for a large international telecom company that uses IPv6. For this reason, you have to run IPv6 on your internal network and you have decided to use only IPv6 addresses.

Your network has two FortiGate units running the RIPng dynamic routing protocol. Both FortiGate units are connected to the ISP router and the internal network. This configuration provides some redundancy for the R&D internal network enabling it to reach the Internet at all times.

All internal computers use RIP routing, so no static routing is required. And all internal computers use IPv6 addresses.

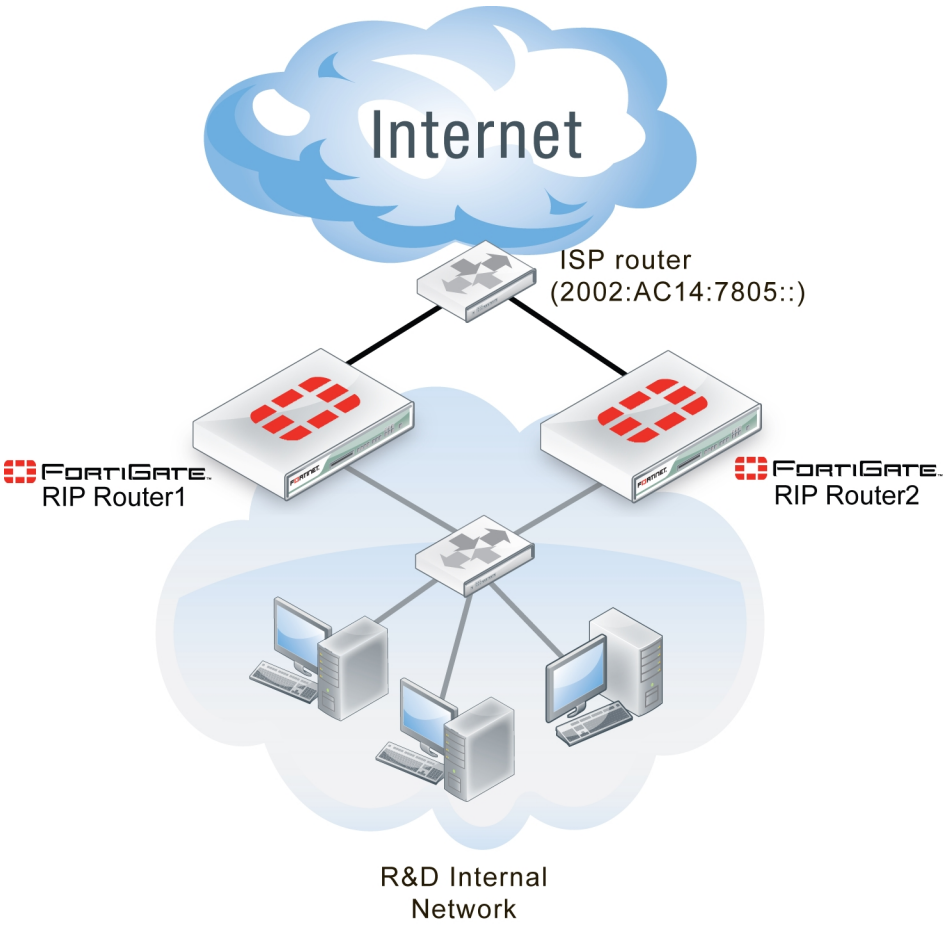
Where possible in this example, the default values will be used or the most general settings. This is intended to provide an easier configuration that will require less troubleshooting.

In this example the routers, networks, interfaces used, and IP addresses are as follows.

RIP example network topology

Network	Router	Interface & Alias	IPv6 address
R&D	Router1	port1 (internal)	2002:A0B:6565:0:0:0:0:0
		port2 (ISP)	2002:AC14:7865:0:0:0:0:0
	Router2	port1 (internal)	2002:A0B:6566:0:0:0:0:0
		port2 (ISP)	2002:AC14:7866:0:0:0:0:0

Network topology for the IPV6 RIPng example



Assumptions

The following assumptions have been made concerning this example.

- All FortiGate units have 5.0 firmware, and are running factory default settings.
- All CLI and web-based manager navigation assumes the unit is running in NAT/Route operating mode, with VDOMs disabled.
- All FortiGate units have interfaces labelled port1 and port2 as required.

- All firewalls have been configured for each FortiGate unit to allow the required traffic to flow across interfaces.
- All network devices are support IPv6 and are running RIPng.

Configuring the FortiGate units system information

Each FortiGate unit needs IPv6 enabled, a new hostname, and interfaces configured.

To configure system information on Router1 - web-based manager

1. Go to **Dashboard > System Information**.
2. For **Host name**, select **Change**.
3. Enter "Router1".
4. Go to **System > Feature Select**.
5. In **Basic Features**, enable **IPv6**, and select **Apply**.
6. Go to **Network > Interfaces**.
7. Edit port1 (internal) interface.
8. Set the following information, and select **OK**.

Alias	internal
IP/Network Mask	2002:A0B:6565::/0
Administrative Access	HTTPS SSH PING
Description	Internal RnD network
Administrative Status	Up

9. Edit port2 (ISP) interface.
10. Set the following information, and select **OK**.

Alias	ISP
IP/Network Mask	2002:AC14:7865::/0
Administrative Access	HTTPS SSH PING
Description	ISP and Internet
Administrative Status	Up

To configure system information on Router1 - CLI

```
config system global
   set hostname Router1
   set gui-ipv6 enable
end
config system interface
   edit port1
      set alias internal
      set allowaccess https ping ssh
      set description "Internal RnD network"
      config ipv6
```

```
      set ip6-address 2002:a0b:6565::/0
    end
  next
  edit port2
    set alias ISP
    set allowaccess https ping ssh
    set description "ISP and Internet"
    config ipv6
      set ip6-address 2002:AC14:7865::
    end
  end
```

To configure system information on Router2 - web-based manager

1. Go to **Dashboard > System Information**.
2. For **Host name**, select **Change**.
3. Enter "Router2".
4. Go to **System > Feature Select**.
5. In **Basic Features**, enable **IPv6**, and select **Apply**.
6. Go to **Network > Interfaces**.
7. Edit port1 (internal) interface.
8. Set the following information, and select **OK**.

Alias	internal
IP/Network Mask	2002:A0B:6566::/0
Administrative Access	HTTPS SSH PING
Description	Internal RnD network
Administrative Status	Up

9. Edit port2 (ISP) interface.
10. Set the following information, and select **OK**.

Alias	ISP
IP/Network Mask	2002:AC14:7866::/0
Administrative Access	HTTPS SSH PING
Description	ISP and Internet
Administrative Status	Up

To configure system information on Router2 - CLI

```
config system global
  set hostname Router2
  set gui-ipv6 enable
end
config system interface
```

```
edit port1
   set alias internal
   set allowaccess https ping ssh
   set description "Internal RnD network"
   config ipv6
      set ip6-address 2002:a0b:6566::/0
   end
next
edit port2
   set alias ISP
   set allowaccess https ping ssh
   set description "ISP and Internet"
   config ipv6
      set ip6-address 2002:AC14:7866::
   end
end
```

Configuring RIPng on FortiGate units

Now that the interfaces are configured, you can configure RIPng on the FortiGate units.

There are only two networks and two interfaces to include — the internal network, and the ISP network. There is no redistribution, and no authentication. In RIPng there is no specific command to include a subnet in the RIP broadcasts. There is also no information required for the interfaces beyond including their name.

As this is a CLI only configuration, configure the ISP router and the other FortiGate unit as neighbors. This was not part of the previous example as this feature is not offered in the web-based manager. Declaring neighbors in the configuration like this will reduce the discovery traffic when the routers start up.

Since RIPng is not supported in the web-based manager, this section will only be entered in the CLI.

To configure RIPng on Router1 - CLI

```
config router ripng
   config interface
      edit port1
      next
      edit port2
      end
   config neighbor
      edit 1
         set interface port1
         set ipv6 2002:a0b:6566::/0
      next
      edit 2
         set interface port2
         set ipv6 2002:AC14:7805::/0
      end
```

To configure RIPng on Router2 - CLI

```
config router ripng
   config interface
      edit port1
      next
      edit port2
      end
```

```
config neighbor
   edit 1
      set interface port1
      set ipv6 2002:a0b:6565::/0
   next
   edit 2
      set interface port2
      set ipv6 2002:AC14:7805::/0
   end
```

Configuring other network devices

The other devices on the internal network all support IPv6, and are running RIPng where applicable. They only need to know the internal interface network addresses of the FortiGate units.

The ISP routers need to know the FortiGate unit information such as IPv6 addresses.

Testing the configuration

In addition to normal testing of your network configuration, you must also test the IPv6 part of this example.

For troubleshooting problems with your network, see the FortiOS Handbook Troubleshooting chapter.

For troubleshooting problems with RIP, see RIPng — RIP and IPv6 on page 420.

Testing the IPv6 RIPng information

There are some commands to use when checking that your RIPng information is correct on your network. These are useful to check on your RIPng FortiGate units on your network. Comparing the output between devices will help you understand your network better, and also track down any problems.

```
diagnose ipv6 address list
```

View the local scope IPv6 addresses used as next-hops by RIPng on the FortiGate unit.

```
diagnose ipv6 route list
```

View ipv6 addresses that are installed in the routing table.

```
get router info6 routing-table
```

View the routing table. This information is almost the same as the previous command (diagnose ipv6 route list) however it is presented in an easier to read format.

```
get router info6 rip interface external
```

View brief output on the RIP information for the interface listed. The information includes if the interface is up or down, what routing protocol is being used, and whether passive interface or split horizon are enabled.

```
get router info6 neighbor-cache list
```

View the IPv6/MAC address mapping. This also displays the interface index and name associated with the address.

Border Gateway Protocol (BGP)

This section describes Border Gateway Protocol (BGP).

The following topics are included in this section:

BGP background and concepts

The border gateway protocol contains two distinct subsets — internal BGP (iBGP) and external BGP (eBGP). iBGP is intended for use within your own networks. eBGP is used to connect many different networks together, and is the main routing protocol for the Internet backbone. FortiGate units support iBGP, and eBGP only for communities.

The following topics are included in this section:

- Background
- Parts and terminology of BGP
- How BGP works

Background

BGP was first used in 1989. The current version, BGP-4, was released in 1995 and is defined in RFC 1771. That RFC has since been replaced by the more recent RFC 4271. The main benefits of BGP-4 are classless inter-domain routing, and aggregate routes. BGP is the only routing protocol to use TCP for a transport protocol. Other routing protocols use UDP.

BGP makes routing decisions based on path, network policies and rulesets instead of the hop-count metric as RIP does, or cost-factor metrics as OSPF does.

BGP-4+ supports IPv6. It was introduced in RFC 2858 and RFC 2545.

BGP is the routing protocol used on the Internet. It was designed to replace the old Exterior Gateway Protocol (EGP) which had been around since 1982, and was very limited. In doing so, BGP enabled more networks to take part in the Internet backbone to effectively decentralize it and make the Internet more robust, and less dependent on a single ISP or backbone network.

Parts and terminology of BGP

In a BGP network, there are some terms that need to be explained before going ahead. Some parts of BGP are not explained here as they are common to other dynamic routing protocols as well. When determining your network topology, note that the number of available or supported routes is not set by the configuration but depends on your FortiGate's available memory. For more information on parts of BGP that are not listed here, see Dynamic Routing Overview on page 2371.

BGP and IPv6

FortiGate units support IPv6 over BGP using the same `config router bgp` command as IPv4, but different subcommands.

The main CLI keywords have IPv6 equivalents that are identified by the "6" on the end of the keyword, such as with `config network6` or `set allowas-in6`. For more information about IPv6 BGP keywords, see the FortiGate CLI Reference.

IPv6 BGP commands include:

```
config router bgp
   set activate6 {enable | disable}
   set allowas-in6 <max_num_AS_integer>
   set allowas-in-enable6 {enable | disable}
   set as-override6 {enable | disable}
   set attribute-unchanged6 [as-path] [med] [next-hop]
   set capability-default-originate6 {enable | disable}
   set capability-graceful-restart6 {enable | disable}
   set capability-orf6 {both | none | receive | send}
   set default-originate-route-map6 <routemap_str>
   set distribute-list-in6 <access-list-name_str>
   set distribute-list-out6 <access-list-name_str>
   set filter-list-in6 <aspath-list-name_str>
   set filter-list-out6 <aspath-list-name_str>
   set maximum-prefix6 <prefix_integer>
   set maximum-prefix-threshold6 <percentage_integer>
   set maximum-prefix-warning-only6 {enable | disable}
   set next-hop-self6 {enable | disable}
   set prefix-list-in6 <prefix-list-name_str>
   set prefix-list-out6 <prefix-list-name_str>
   set remove-private-as6 {enable | disable}
   set route-map-in6 <routemap-name_str>
   set route-map-out6 <routemap-name_str>
   set route-reflector-client6 {enable | disable}
   set route-server-client6 {enable | disable}
   set send-community6 {both | disable | extended | standard}
   set soft-reconfiguration6 {enable | disable}
   set unsuppress-map6 <route-map-name_str>
   config network6
   config redistribute6
end
```

Roles of routers in BGP networks

Dynamic routing has a number of different roles routers can fill such as those covered in Dynamic Routing Overview on page 2371. BGP has a number of custom roles that routers can fill. These include:

- Speaker routers
- Peer routers or neighbors
- Route reflectors (RR)

Speaker routers

Any router configured for BGP is considered a BGP speaker. This means that a speaker router advertises BGP routes to its peers.

Any routers on the network that are not speaker routers, are not treated as BGP routers.

Peer routers or neighbors

In a BGP network, all neighboring BGP routers or peer routers are routers that are connected to your FortiGate unit. Your FortiGate unit learns about all other routers through these peers.

You need to manually configure BGP peers on your FortiGate unit as neighbors. Otherwise these routers will not be seen as peers, but instead as simply other routers on the network that don't support BGP. You can optionally use MD5 authentication to password protect BGP sessions with those neighbors. (see RFC 2385).

You can configure up to 1000 BGP neighbors on your FortiGate unit. You can clear all or some BGP neighbor connections (sessions) using the `execute router clear bgp` command.

For example, if you have 10 routes in the BGP routing table and you want to clear the specific route to IP address 10.10.10.1, enter the command:

```
execute router clear bgp ip 10.10.10.1
```

To remove all routes for AS number 650001, enter the command:

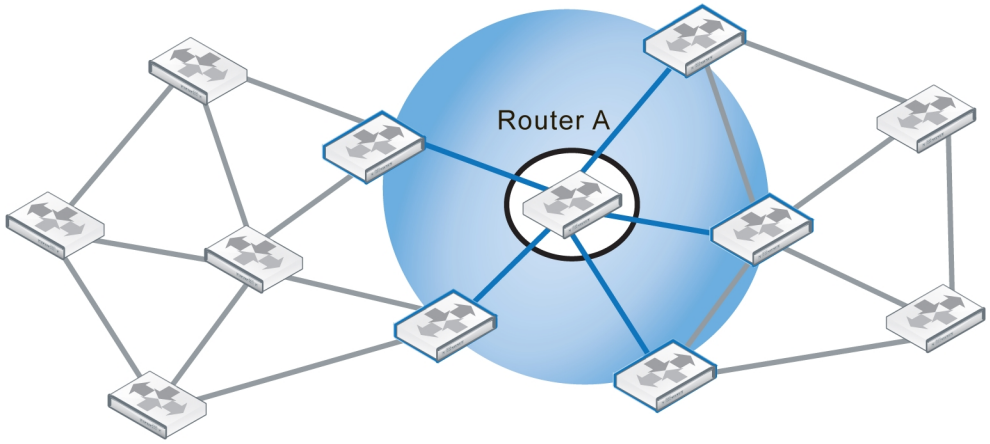
```
execute router clear bgp as 650001
```

To remove route flap dampening information for the 10.10.0.0/16 subnet, enter the command:

```
execute router clear bgp dampening 10.10.0.0/16
```

In Figure 1, Router A is directly connected to five other routers in a network that contains 12 routers overall. These routers, the ones in the blue circle, are Router A's peers or neighbors.

Router A and its 5 peer routers



As a minimum, when configuring BGP neighbors you must enter their IP address, and the AS number (remote-as). This is all the information the web-based manager interface allows you to enter for a neighbor.

The BGP commands related to neighbors are quite extensive and include:

```
config router bgp
   config neighbor
      edit <neighbor_address_ipv4>
         set activate {enable | disable}
         set advertisement-interval <seconds_integer>
         set allowas-in <max_num_AS_integer>
         set allowas-in-enable {enable | disable}
         set as-override {enable | disable}
         set attribute-unchanged [as-path] [med] [next-hop]
         set bfd {enable | disable}
         set capability-default-originate {enable | disable}
         set capability-dynamic {enable | disable}
         set capability-graceful-restart {enable | disable}
         set capability-orf {both | none | receive | send}
```

```
            set capability-route-refresh {enable | disable}
            set connect-timer <seconds_integer>
            set description <text_str>
            set distribute-list-in <access-list-name_str>
            set distribute-list-out <access-list-name_str>
            set dont-capability-negotiate {enable | disable}
            set ebgp-enforce-multihop {enable | disable}
            set ebgp-multihop {enable | disable}
            set ebgp-multihop-ttl <seconds_integer>
            set filter-list-in <aspath-list-name_str>
            set filter-list-out <aspath-list-name_str>
            set holdtime-timer <seconds_integer>
            set interface <interface-name_str>
            set keep-alive-timer <seconds_integer>
            set maximum-prefix <prefix_integer>
            set maximum-prefix-threshold <percentage_integer>
            set maximum-prefix-warning-only {enable | disable}
            set next-hop-self {enable | disable}
            set passive {enable | disable}
            set password <string>
            set prefix-list-in <prefix-list-name_str>
            set prefix-list-out <prefix-list-name_str>
            set remote-as <id_integer>
            set remove-private-as {enable | disable}
            set retain-stale-time <seconds_integer>
            set route-map-in <routemap-name_str>
            set route-map-out <routemap-name_str>
            set route-reflector-client {enable | disable}
            set route-server-client {enable | disable}
            set send-community {both | disable | extended | standard}
            set shutdown {enable | disable}
            set soft-reconfiguration {enable | disable}
            set strict-capability-match {enable | disable}
            set unsuppress-map <route-map-name_str>
            set update-source <interface-name_str>
            set weight <weight_integer>
        end
    end
end
```

Route reflectors (RR)

Route reflectors in BGP concentrate route updates so other routers need only talk to the route reflectors to get all the updates. This results in smaller routing tables, fewer connections between routers, faster responses to network topology changes, and less administration bandwidth. BGP route reflectors are defined in RFC 1966.

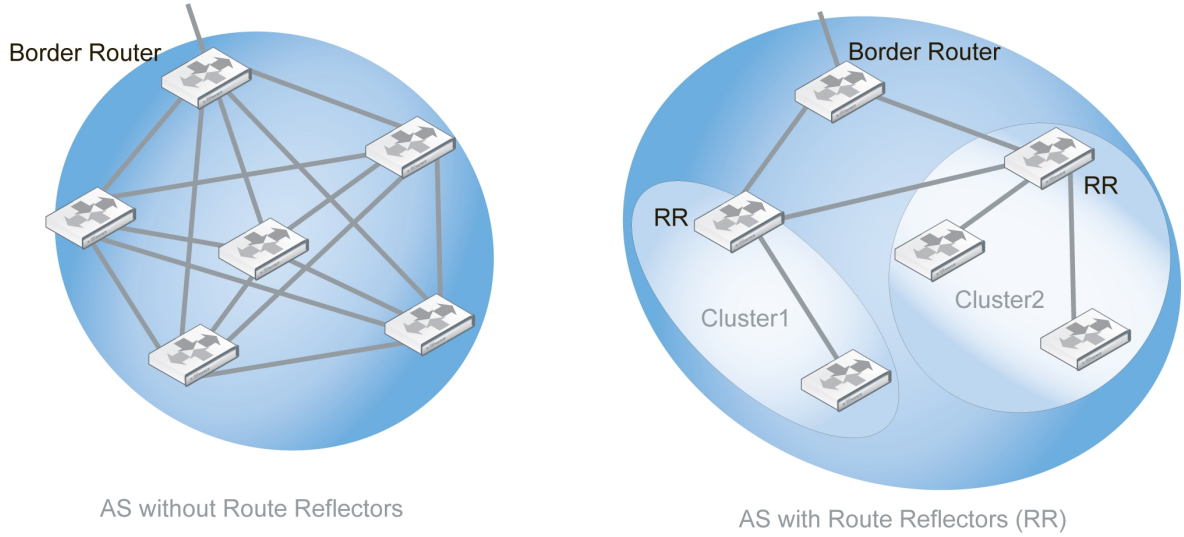
In a BGP route reflector configuration, the AS is divided into different clusters that each include client and reflector routers. The client routers supply the reflector routers with the client's route updates. The reflectors pass this information along to other route reflectors and border routers. Only the reflectors need to be configured, not the clients — the clients will find the closest reflector and communicate with it automatically. The reflectors communicate with each other as peers. FortiGate units can be configured as either reflectors or clients.

Since route reflectors are processing more than the client routers, the reflectors should have more resources to handle the extra workload.

Smaller networks running BGP typically don't require route reflectors (RR). However, RR is a useful feature for large companies, where their AS may include 100 routers or more. For example, for a full mesh 20 router configuration within an AS, there would have to be 190 unique BGP sessions — just for routing updates within the AS. The number of sessions jumps to 435 sessions for just 30 routers, or 4950 sessions for 100 routers. From these numbers, its plain that updating this many sessions will quickly consume the limited bandwidth and processing resources of the routers involved.

The following diagram illustrates how route reflectors can improve the situation when only six routers are involved. The AS without route reflectors requires 15 sessions between the routers. In the AS with route reflectors, the two route reflectors receive route updates from the reflector clients (unlabeled routers in the diagram) in their cluster as well as other route reflectors and pass them on to the border router. The RR configuration only require six sessions. This example shows a reduction of 60% in the number of required sessions.

Required sessions within an AS with and without route reflectors



The BGP commands related to route reflectors includes:

```
config router bgp
   config neighbor
      set route-reflector-client {enable | disable}
      set route-server-client {enable | disable}
   end
end
```

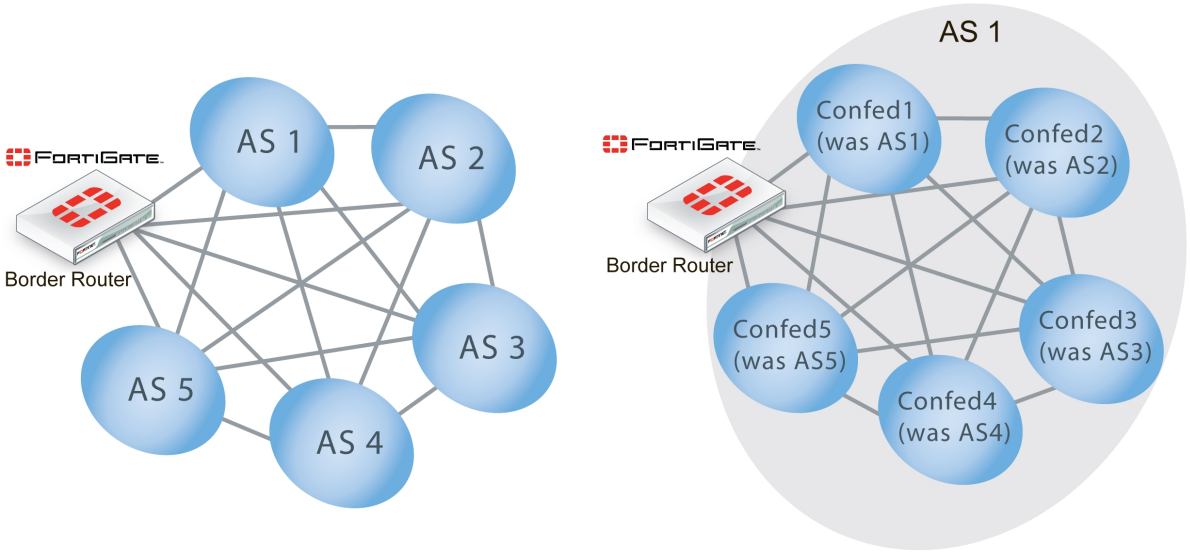
Confederations

Confederations were introduced to reduce the number of BGP advertisements on a segment of the network, and reduce the size of the routing tables. Confederations essentially break up an AS into smaller units. Confederations are defined in RFC 3065 and RFC 1965.

Within a confederation, all routers communicate with each other in a full mesh arrangement. Communications between confederations is more like inter-AS communications in that many of the attributes are changed as they would be for BGP communications leaving the AS, or eBGP.

Confederations are useful when merging ASs. Each AS being merged can easily become a confederation, requiring few changes. Any additional permanent changes can then be implemented over time as required. The figure below shows the group of ASs before merging, and the corresponding confederations afterward as part of the single AS with the addition of a new border router. It should be noted that after merging if the border router becomes a route reflector, then each confederation only needs to communicate with one other router, instead of five others.

AS merging using confederations



Multiple ASes before merging

Combined AS with confederations and new FortiGate unit border router

Confederations and route reflectors perform similar functions — they both sub-divide large ASes for more efficient operation. They differ in that route reflector clusters can include routers that are not members of a cluster, where routers in a confederation must belong to that confederation. Also, confederations place their confederation numbers in the AS_PATH attribute making it easier to trace.

It is important to note that while confederations essentially create sub-ASs, all the confederations within an AS appear as a single AS to external ASs.

Confederation related BGP commands include:

```
config router bgp
   set confederation-identifier <peerid_integer>
end
```

BGP conditional advertisements

Normally, routes are propagated regardless of the existence of a different path. The BGP conditional advertisement feature allows a route not to be advertised based on existence or non-existence of other routes. With this new feature, a child table under bgp.neighbor is introduced. Any route matched by one of the route-map specified in the table will be advertised to the peer based on the corresponding condition route-map.

You can enable and disable conditional advertisements using the CLI.

To configure BGP conditional advertisements - CLI:

```
config router bgp
   set as 3
      config neighbor
         edit "10.10.10.10"
            set remote-as 3
               config conditional-advertise
                  edit "route-map-to-match-sending"
                     set condition-routemap "route-map-to-match-condition"
                     set condition-type [exist | non-exist]
                  next
               end
            next
         end
```

BGP Neighbor Groups

The BGP Neighbor Groups feature allows a large number of neighbors to be configured automatically based on a range of neighbors' source addresses.

To configure BGP Neighbor Groups - CLI:

Start by adding a BGP neighbor group:

```
config router bgp
   config neighbor-group
      edit <neighbor-group-name>
         set remote-as 100
   ...
```

(All options for BGP neighbor are supported except `password`.)

```
end
```

Then add a BGP neighbor range:

```
config router bgp
   config neighbor-range
      edit 1
         set prefix 192.168.1.0/24
         set max-neighbor-num 100
         set neighbor-group <neighbor-group-name>
      next
   end
```

Network Layer Reachability Information (NLRI)

Network Layer Reachability Information (NLRI) is unique to BGP-4. It is sent as part of the update messages sent between BGP routers, and contains information necessary to supernet, or aggregate route, information. The NLRI includes the length and prefix that when combined are the address of the aggregated routes referred to.

There is only one NLRI entry per BGP update message.

BGP attributes

Each route in a BGP network has a set of attributes associated with it. These attributes define the route, and are modified as required along the route.

BGP can work well with mostly default settings, but if you are going to change settings you need to understand the roles of each attribute and how they affect those settings.

The BGP attributes include:

AS_PATH	A list of ASes a route has passed through. See AS_PATH on page 433.
MULTI_EXIT_DESC (MED)	Which router to use to exit an AS with more than one external connection. See MULTI_EXIT_DESC (MED) on page 434.
COMMUNITY	Used to apply attributes to a group of routes. See COMMUNITY on page 434.
NEXT_HOP	Where the IP packets should be forwarded to, like a gateway in static routing. See NEXT_HOP on page 435.
ATOMIC_AGGREGATE	Used when routes have been summarized to tell downstream routers not to de-aggregate the route. See ATOMIC_AGGREGATE on page 435.
ORIGIN	Used to determine if the route is from the local AS or not. See ORIGIN on page 435.
LOCAL_PREF	Used only within an AS to select the best route to a location (like MED)

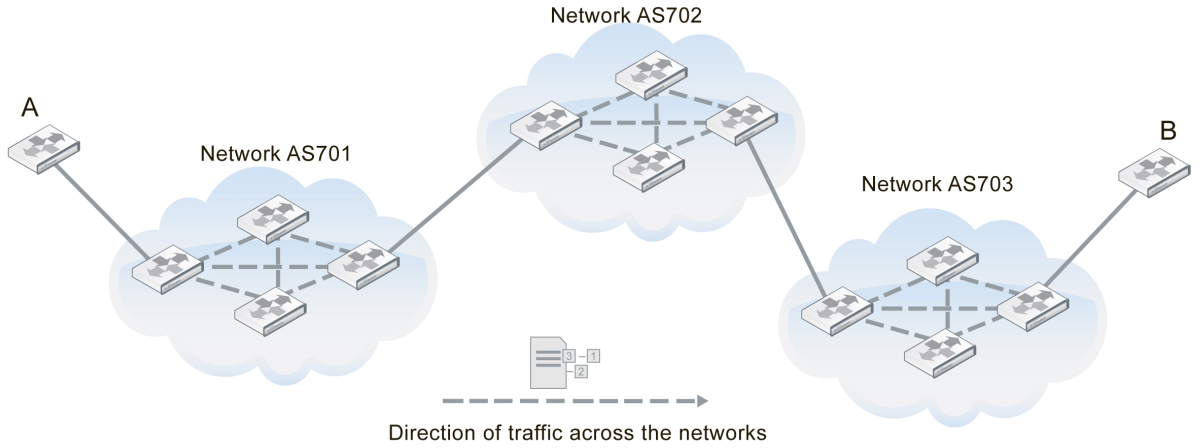
Inbound policies on FortiGate units can change the NEXT-HOP,LOCAL-PREF, MED and AS-PATH attributes of an internal BGP (iBGP) route for its local route selection purposes. However, outbound policies on the unit cannot affect these attributes.

AS_PATH

AS_PATH is the BGP attribute that keeps track of each AS a route advertisement has passed through. AS_PATH is used by confederations and by exterior BGP (EBGP) to help prevent routing loops. A router knows there is a loop if it receives an AS_PATH with that routers AS in it. The figure below shows the route between router A and router B. The AS_PATH from A to B would read 701,702,703 for each AS the route passes through.

As of the start of 2010, the industry upgraded from 2-byte to 4-byte AS_PATHs. This upgrade was due to the imminent exhaustion of 2-byte AS_PATH numbers. FortiOS supports 4-byte AS_PATHs in its BGP implementation.

AS_PATH of 701,702, 703 between routers A and B



The BGP commands related to AS_PATH include:

```
config router bgp
   set bestpath-as-path-ignore {enable | disable}
end
```

MULTI_EXIT_DESC (MED)

BGP AS systems can have one or more routers that connect them to other ASes. For ASes with more than one connecting router, the Multi-Exit Discriminator (MED) lists which router is best to use when leaving the AS. The MED is based on attributes such as delay. It is a recommendation only, as some networks may have different priorities.

BGP updates advertise the best path to a destination network. When the FortiGate unit receives a BGP update, the FortiGate unit examines the Multi-Exit Discriminator (MED) attribute of potential routes to determine the best path to a destination network before recording the path in the local FortiGate unit routing table.

FortiGate units have the option to treat any routes without an MED attribute as the worst possible routing choice. This can be useful because a lack of MED information is a lack of routing information which can be suspicious — possibly a hacking attempt or an attack on the network. At best it signifies an unreliable route to select.

The BGP commands related to MED include:

```
config router bgp
   set always-compare-med {enable | disable}
   set bestpath-med-confed {enable | disable}
   set bestpath-med-missing-as-worst {enable | disable}
   set deterministic-med {enable | disable}
   config neighbor
      set attribute-unchanged [as-path] [med] [next-hop]
   end
end
```

COMMUNITY

A community is a group of routes that have the same routing policies applied to them. This saves time and resources. A community is defined by the COMMUNITY attribute of a BGP route.

The FortiGate unit can set the COMMUNITY attribute of a route to assign the route to predefined paths (see RFC 1997). The FortiGate unit can examine the COMMUNITY attribute of learned routes to perform local filtering and/or redistribution.

The BGP commands related to COMMUNITY include:

```
config router bgp
   set send-community {both | disable | extended | standard}
end
```

NEXT_HOP

The NEXT_HOP attribute says what IP address the packets should be forwarded to next. Each time the route is advertised, this value is updated. The NEXT_HOP attribute is much like a gateway in static routing.

FortiGate units allow you to to change the advertising of the FortiGate unit's IP address (instead of the neighbor's IP address) in the NEXT_HOP information that is sent to IBGP peers. This is changed with the config neighbor, set next-hop-self command.

The BGP commands related to NEXT_HOP include:

```
config router bgp
   config neighbor
      set attribute-unchanged [as-path] [med] [next-hop]
      set next-hop-self {enable | disable}
   end
end
```

ATOMIC_AGGREGATE

The ATOMIC_AGGREGATE attribute is used when routes have been summarized. It indicates which AS and which router summarize the routes. It also tells downstream routers not to de-aggregate the route. Summarized routes are routes with similar information that have been combined, or aggregated, into one route that is easier to send in updates. When it reaches its destination, the summarized routes are split back up into the individual routes.

Your FortiGate unit doesn't specifically set this attribute in the BGP router command, but it is used in the route map command.

The commands related to ATOMIC_AGGREGATE include:

```
config router route-map
   edit <route_map_name>
      config rule
      edit <route_map_rule_id>
         set set-aggregator-as <id_integer>
         set set-aggregator-ip <address_ipv4>
         set set-atomic-aggregate {enable | disable}
      end
   end
end
```

ORIGIN

The ORIGIN attribute records where the route came from. The options can be IBGP, EBGP, or incomplete. This information is important because internal routes (IBGP) are by default higher priority than external routes (EBGP). However incomplete ORIGINs are the lowest priority of the three.

The commands related to ORIGIN include:

```
config router route-map
   edit <route_map_name>
      set comments <string>
      config rule
      edit <route_map_rule_id>
         set match-origin {egp | igp | incomplete | none}
      end
   end
end
```

How BGP works

BGP is a link-state routing protocol and keeps link-state information about the status of each network link it has connected. A BGP router receives information from its peer routers that have been defined as neighbors. BGP routers listen for updates from these configured neighboring routers on TCP port 179.

A BGP router is a finite state machine with six various states for each connection. As two BGP routers discover each other, and establish a connection they go from the idle state, through the various states until they reach the established state. An error can cause the connection to be dropped and the state of the router to be reset to either active or idle. These errors can be caused by: TCP port 179 not being open, a random TCP port above port 1023 not being open, the peer address being incorrect, or the AS number being incorrect.

When BGP routers start a connection, they negotiate which (if any) optional features will be used such as multiprotocol extensions that can include IPv6 and VPNs.

IBGP versus EBGP

When you read about BGP, often you see EBGP or IBGP mentioned. These are both BGP routing, but BGP used in different roles. Exterior BGP (EBGP) involves packets crossing multiple autonomous systems (ASes) where interior BGP (IBGP) involves packets that stay within a single AS. For example the AS_PATH attribute is only useful for EBGP where routes pass through multiple ASes.

These two modes are important because some features of BGP are only used for one of EBGP or IBGP. For example confederations are used in EBGP, and route reflectors are only used in IBGP. Also routes learned from IBGP have priority over EBGP learned routes.

FortiGate units have some commands specific to EBGP. These include:

- automatically resetting the session information to external peers if the connection goes down — `set fast-external-failover {enable | disable}`
- setting an administrative distance for all routes learned from external peers (must also configure local and internal distances if this is set) — `set distance-external <distance_integer>`
- enforcing EBGP multihops and their TTL (number of hops) — `set ebgp-enforce-multihop {enable | disable}` and `set ebgp-multihop-ttl <seconds_integer>`

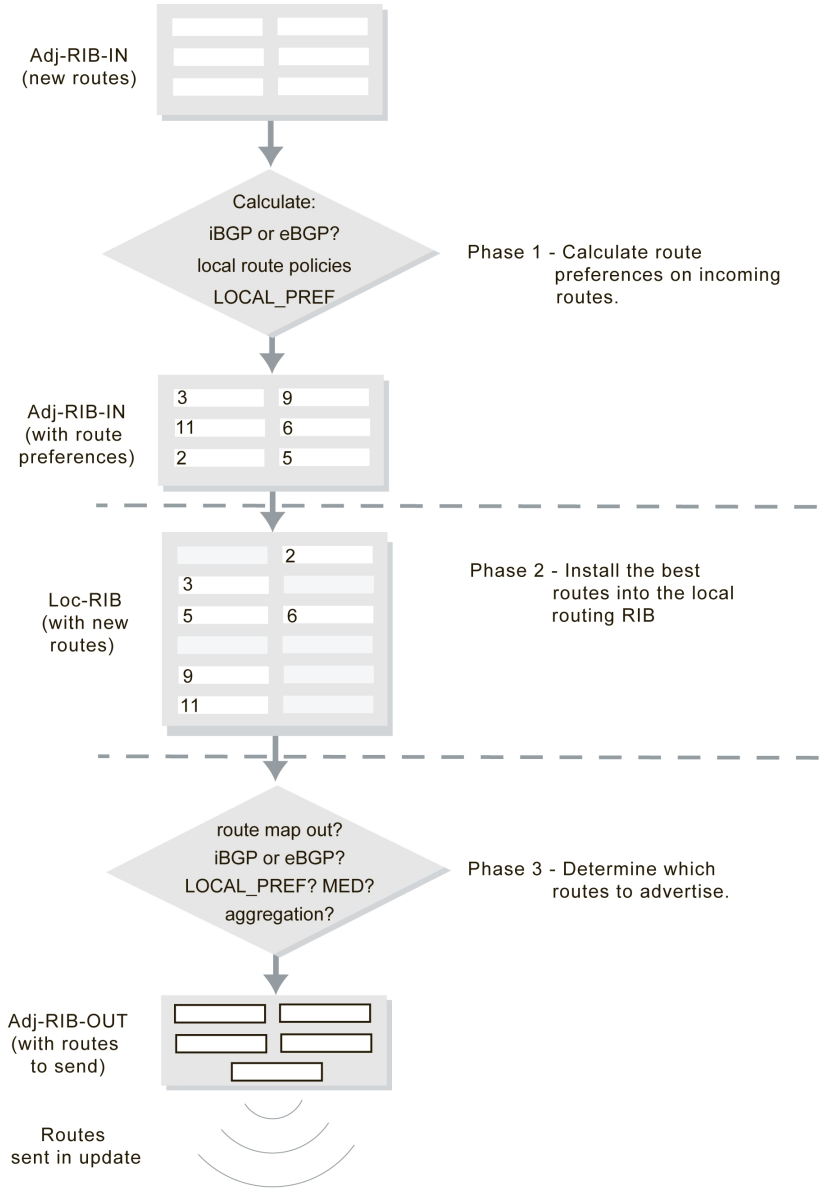
BGP path determination — which route to use

Firstly, recall that the number of available or supported routes is not set by the configuration but depends on your FortiGate's available memory. All learned routes and their attributes come into the BGP router in raw form. Before routes are installed in the routing table or are advertised to other routers, three levels of decisions must be made.

The three phases of BGP best path determination do not change. However, some manufacturers have added more information to the process, such as Cisco's WEIGHT attribute to enable an administrator to force one route's selection over another.

There is one Adj-RIB-IN and Adj-RIB-OUT for each configured neighbor. They are updated when the FortiGate unit receives BGP updates, or when the FortiGate unit sends out BGP updates.

Three phases of BGP routing decision



Decision phase 1

At this phase, the decision is to calculate how preferred each route and its NRLI are the Adjacent Routing Information Base Incoming (Adj-RIBs-In) compared to the other routes. For internal routes (IBGP), policy information or LOCAL_PREF is used. For external peer learned routes, it is based strictly on policy. These rules set up a list of which routes are most preferred going into Phase 2.

Decision phase 2

Phase 2 involves installing the best route to each destination into the local Routing Information Base (Loc-RIB). Effectively, the Loc-RIB is the master routing table. Each route from Phase 1 has their NEXT_HOP checked to ensure the destination is reachable. If it is reachable, the AS_PATH is checked for loops. After that, routes are installed based on the following decision process:

- If there is only one route to a location, it is installed.
- If multiple routes to the same location, use the most preferred route from Level 1.
- If there is a tie, break the tie based on the following in descending order of importance: shortest AS_PATH, smallest ORIGIN number, smallest MED, EBGP over IBGP, smallest metric or cost for reaching the NEXT_HOP, BGP identifier, and lowest IP address.

Note that the new routes that are installed into the Loc-RIB are in addition to any existing routes in the table. Once Phase 2 is completed the Loc-RIB will consist of the best of both the new and older routes.

Decision phase 3

Phase 3 is route distribution or dissemination. This is the process of deciding which routes the router will advertise. If there is any route aggregation or summarizing, it happens here. Also any route filtering from route maps happens here.

Once Phase 3 is complete, an update can be sent out to update the neighbor of new routes.

Aggregate routes and addresses

BGP4 allows classless routing, which uses netmasks as well as IP addresses. This classless routing enables the configuration of aggregate routes by stating the address bits the aggregated addresses have in common. For more information, see Dynamic Routing Overview on page 2371.

The ATOMIC_AGGREGATE attribute informs routers that the route has been aggregated, and should not be de-aggregated. An associated AGGREGATOR attribute include the information about the router that did the aggregating including its AS.

The BGP commands associated with aggregate routes and addresses are:

```
config router bgp
   config aggregate-address
      edit <aggr_addr_id>
      set as-set {enable | disable}
      set prefix <address_ipv4mask>
      set summary-only {enable | disable}
   end
   config aggregate-address6
      edit <aggr_addr_id>
      set as-set {enable | disable}
      set prefix6 <address_ipv6mask>
      set summary-only {enable | disable}
   end
```

Troubleshooting BGP

There are some features in BGP that are used to deal with problems that may arise. Typically the problems with a BGP network that has been configured, involve routes going offline frequently. This is called route flap and causes problems for the routers using that route.

Clearing routing table entries

To see if a new route is being properly added to the routing table, you can clear all or some BGP neighbor connections (sessions) using the `execute router clear bgp` command.

For example, if you have 10 routes in the BGP routing table and you want to clear the specific route to IP address 10.10.10.1, enter the command:

```
execute router clear bgp ip 10.10.10.1
```

To remove all routes for AS number 650001, enter the command:

```
execute router clear bgp as 650001
```

Route flap

When routers or hardware along a route go offline and back online that is called a route flap. Flapping is the term if these outages continue, especially if they occur frequently.

Route flap is a problem in BGP because each time a peer or a route goes down, all the peer routers that are connected to that out-of-service router advertise the change in their routing tables which creates a lot of administration traffic on the network. And the same traffic happens again when that router comes back online. If the problem is something like a faulty network cable that wobbles on and offline every 10 seconds, there could easily be overwhelming amounts of routing updates sent out unnecessarily.

Another possible reason for route flap occurs with multiple FortiGate units in HA mode. When an HA cluster fails over to the secondary unit, other routers on the network may see the HA cluster as being offline resulting in route flap. While this doesn't occur often, or more than once at a time, it can still result in an interruption in traffic which is unpleasant for network users. The easy solution for this problem is to increase the timers on the HA cluster, such as TTL timers, so they do not expire during the failover process. Also configuring graceful restart on the HA cluster will help with a smooth failover.

The first method of dealing with route flap should be to check your hardware. If a cable is loose or bad, it can easily be replaced and eliminate the problem. If an interface on the router is bad, either avoid using that interface or swap in a functioning router. If the power source is bad on a router, either replace the power supply or use a power conditioning backup power supply. These quick and easy fixes can save you from configuring more complex BGP options. However if the route flap is from another source, configuring BGP to deal with the outages will ensure your network users uninterrupted service.

Some methods of dealing with route flap in BGP include:

- Holddown timer
- Dampening
- Graceful restart
- Bi-directional forwarding detection (BFD)

Holddown timer

The first line of defence to a flapping route is the hold down timer. This timer reduces how frequently a route going down will cause a routing update to be broadcast.

Once activated, the holddown timer won't allow the FortiGate unit to accept any changes to that route for the duration of the timer. If the route flaps five times during the timer period, only the first outage will be recognized by the FortiGate unit — for the duration of the other outages there will be no changes because the Fortigate unit is essentially treating this router as down. After the timer expires, if the route is still flapping it will happen all over again.

Even if the route isn't flapping — if it goes down, comes up, and stays back up — the timer still counts down and the route is ignored for the duration of the timer. In this situation the route will be seen as down longer than it really is, but there will be only the one set of route updates. This is not a problem in normal operation because updates are not frequent.

Also the potential for a route to be treated as down when it is really up can be viewed as a robustness feature. Typically you do not want most of your traffic being routed over an unreliable route. So if there is route flap going on, it is best to avoid that route if you can. This is enforced by the holddown timer.

How to configure the holddown timer

There are three different route flapping situations that can occur: the route goes up and down frequently, the route goes down and back up once over a long period of time, or the route goes down and stays down for a long period of time. These can all be handled using the holddown timer.

For example, your network has two routes that you want to set the holddown timer for. One is your main route (to 10.12.101.4) that all your Internet traffic goes through, and it can't be down for long if its down. The second is a low speed connection to a custom network that is used infrequently (to 10.13.101.4). The holddown timer for the main route should be fairly short, lets say 60 seconds instead of the default 180 seconds. The second route timer can be left at the default or even longer since it is rarely used. In your BGP configuration this looks like:

```
config router bgp
   config neighbor
   edit 10.12.101.4
      set holddown-timer 60
   next
   edit 10.13.101.4
      set holddown-timer 180
   next
   end
end
```

Dampening

Dampening is a method used to limit the amount of network problems due to flapping routes. With dampening the flapping still occurs, but the peer routers pay less and less attention to that route as it flaps more often. One flap doesn't start dampening, but the second starts a timer where the router will not use that route — it is considered unstable. If the route flaps again before the timer expires, the timer continues to increase. There is a period of time called the reachability half-life after which a route flap will only be suppressed for half the time. This half-life comes into effect when a route has been stable for a while but not long enough to clear all the dampening completely. For the flapping route to be included in the routing table again, the suppression time must expire.

If the route flapping was temporary, you can clear the flapping or dampening from the FortiGate units cache by using one of the `execute router clear bgp` commands:

```
execute router clear bgp dampening {<ip_address> | <ip/netmask>}
```
or
```
execute router clear bgp flap-statistics {<ip> | <ip/netmask>}
```

For example, to remove route flap dampening information for the 10.10.0.0/16 subnet, enter the command:

```
execute router clear bgp dampening 10.10.0.0/16
```

The BGP commands related to route dampening are:

```
config router bgp
   set dampening {enable | disable}
```

```
    set dampening-max-suppress-time <minutes_integer>
    set dampening-reachability-half-life <minutes_integer>
    set dampening-reuse <reuse_integer>
    set dampening-route-map <routemap-name_str>
    set dampening-suppress <limit_integer>
    set dampening-unreachability-half-life <minutes_integer>
end
```

Graceful restart

BGP4 has the capability to gracefully restart.

In some situations, route flap is caused by routers that appear to be offline but the hardware portion of the router (control plane) can continue to function normally. One example of this is when some software is restarting or being upgraded, but the hardware can still function normally.

Graceful restart is best used for these situations where routing will not be interrupted, but the router is unresponsive to routing update advertisements. Graceful restart does not have to be supported by all routers in a network, but the network will benefit when more routers support it.

FortiGate HA clusters can benefit from graceful restart. When a failover takes place, the HA cluster will advertise it is going offline, and will not appear as a route flap. It will also enable the new HA main unit to come online with an updated and usable routing table — if there is a flap the HA cluster routing table will be out of date.

For example, your FortiGate unit is one of four BGP routers that send updates to each other. Any of those routers may support graceful starting—when a router plans to go offline, it will send out a message to its neighbors how long it expects to be before being back online. That way its neighbor routers don't remove it from their routing tables. However if that router isn't back online when expected, the routers will mark it offline. This prevents routing flap and its associated problems.

Scheduled time offline

Graceful restart is a means for a router to advertise it is going to have a scheduled shutdown for a very short period of time. When neighboring routers receive this notice, they will not remove that router from their routing table until after a set time elapses. During that time if the router comes back online, everything continues to function as normal. If that router remains offline longer than expected, then the neighboring routers will update their routing tables as they assume that router will be offline for a long time.

FortiGate units support both graceful restart of their own BGP routing software, and also neighboring BGP routers.

For example, if a neighbor of your FortiGate unit, with an IP address of 172.20.120.120, supports graceful restart, enter the command:

```
config router bgp
   config neighbor
   edit 172.20.120.120
      set capability-graceful-restart enable
   end
end
```

If you want to configure graceful restart on your FortiGate unit where you expect the Fortigate unit to be offline for no more than 2 minutes, and after 3 minutes the BGP network should consider the FortiGate unit offline, enter the command:

```
config router bgp
   set graceful-restart enable
   set graceful-restart-time 120
   set graceful-stalepath-time 180
end
```

The BGP commands related to BGP graceful restart are:

```
config router bgp
   set graceful-restart { disable| enable}
   set graceful-restart-time <seconds_integer>
   set graceful-stalepath-time <seconds_integer>
   set graceful-update-delay <seconds_integer>
   config neighbor
      set capability-graceful-restart {enable | disable}
   end
end

execute router restart
```

Before the restart, the router sends its peers a message to say it is restarting. The peers mark all the restarting router's routes as stale, but they continue to use the routes. The peers assume the router will restart and check its routes and take care of them if needed after the restart is complete. The peers also know what services the restarting router can maintain during its restart. After the router completes the restart, the router sends its peers a message to say it is done restarting.

Bi-directional forwarding detection (BFD)

Bi-directional Forwarding Detection (BFD) is a protocol used to quickly locate hardware failures in the network. Routers running BFD communicate with each other, and if a timer runs out on a connection then that router is declared down. BFD then communicates this information to the routing protocol and the routing information is updated.

While BGP can detect route failures, BFD can be configured to detect these failures more quickly allowing faster responses and improved convergence. This can be balanced with the bandwidth BFD uses in its frequent route checking.

Configurable granularity

BFD can run on the entire FortiGate unit, selected interfaces, or on BGP for all configured interfaces. The hierarchy allows each lower level to override the upper level's BFD setting. For example, if BFD was enabled for the FortiGate unit, it could be disabled only for a single interface or for BGP. For information about FortiGate-wide BFD options, see config system settings in the FortiGate CLI Reference.

BFD can only be configured through the CLI.

The BGP commands related to BFD are:

```
config system {setting | interface}
   set bfd {enable | disable | global}
   set bfd-desired-mix-tx <milliseconds>
   set bfd-detect-mult <multiplier>
   set bfd-required-mix-rx <milliseconds>
   set bfd-dont-enforce-src-port {enable | disable}

config router bgp
   config neighbor
      edit <neighbor_address_ipv4>
      set bfd {enable | disable}
```

```
    end
end

get router info bfd neighbor
execute router clear bfd session <src_ipv4> <dst_ipv4> <interface>
```

The `config system` commands allow you to configure whether BFD is enabled in a particular unit/vdom or individual interface, and how often the interface requires sending and receiving of BFD information.

The `config router bgp` commands allow you to set the addresses of the neighbor units that are also running BFD. Both units must be configured with BFD in order to make use of it.

Dual-homed BGP example

This is an example of a small network that uses BGP routing connections to two ISPs. This is a common configuration for companies that need redundant connections to the Internet for their business.

This configuration is for a small company connected to two ISPs. The company has one main office, the Head Office, and uses static routing for internal routing on that network.

Both ISPs use BGP routing, and connect to the Internet directly. They want the company to connect to the ISP networks using BGP. They also use graceful restart to prevent unneeded updates, and use smaller timer values to detect network failures faster.

As can be expected, the company wants to keep their BGP configuration relatively simple and easy to manage. The current configuration has only 3 routers to worry about — the 2 ISP border routers, and the FortiGate unit. This means the FortiGate unit will only have two neighbor routers to configure.

This configuration has the added benefit of being easy to expand if the Company wants to add a remote office in the future.

To keep the configuration simple, the Company is allowing only HTTP, HTTPS, FTP, and DNS traffic out of the local network. This will allow employees access to the Internet and their web-mail.

This section includes the following topics:

- Network layout and assumptions
- Configuring the FortiGate unit
- Configuring other networking devices
- Testing this configuration

Why dual home?

Dual homing means having two separate independent connections to the Internet. Servers in this configuration have also been called bastion hosts and can include DNS servers which require multiple connections.

Benefits of dual homing can include:

- Redundant Internet connection that essentially never fails
- Faster connections through one ISP or the other for some destinations, such as other clients of those ISPs
- Load balancing traffic to your Company network
- Easier to enable more traffic through two connections than upgrading one connection to bigger bandwidth
- Easier to create protection policies for different traffic through a specific ISP

Some companies require reliable Internet access at all times as part of their business. Consider a doctor operating remotely who has their Internet connection fail — the consequences could easily be life or death.

Dual homing is extra expense for the second ISP connection, and more work to configure and maintain the more complex network topology.

Potential dual homing issues

BGP comes with load balancing issues, and dual homing is the same category. BGP does not inherently deal well with load balancing, or getting default routes through BGP. Ideally one connect may be best for certain destinations, but it may not have that traffic routed to it making the load balancing less than perfect. This kind of fine tuning can be very time consuming, and usually results in a best effort situation.

When dual homing is not configured properly, your network may become a link between your ISPs and result in very high traffic between the ISPs that does not originate from your network. The problems with this situation are that your traffic may not have the bandwidth it needs, and you will be paying for a large volume of traffic that is not yours. This problem can be solved by not broadcasting or redistributing BGP routes between the ISPs.

If you learn your default routes from the ISPs in this example, you may run into an asymmetric routing problem where your traffic loops out one ISP and back to you through the other ISP. If you think this may be happening you can turn on asymmetric routing on the FortiGate unit (config system settings, set asymmetric enable) to verify that really is the problem. Turn this feature off once this is established since it disables many features on the FortiGate by disabling stateful inspection. Solutions for this problem can include using static routes for default routes instead of learning them through BGP, or configuring VDOMs on your FortiGate unit to provide a slightly different path back that is not a true loop.

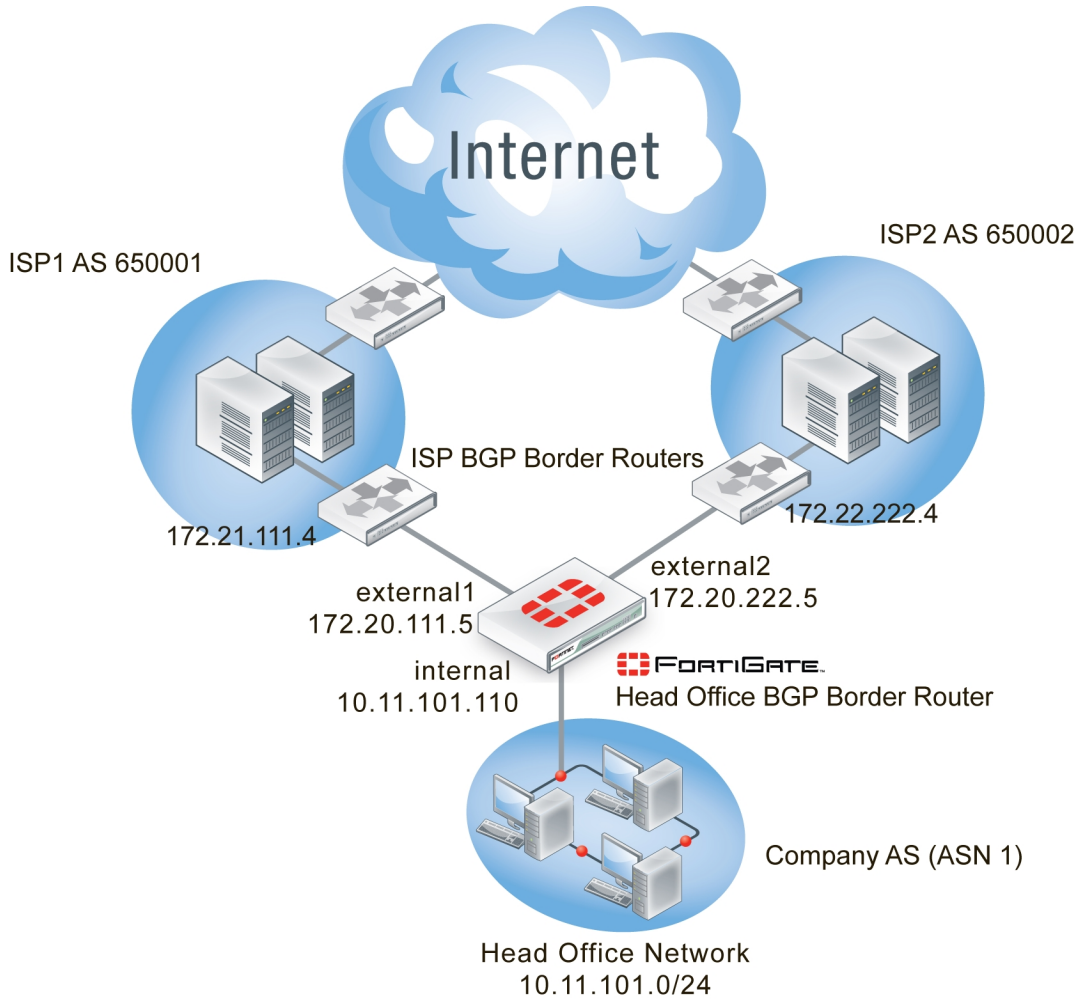
Network layout and assumptions

The network layout for the basic BGP example involves the company network being connected to both ISPs as shown below. In this configuration the FortiGate unit is the BGP border router between the Company AS, ISP1's AS, and ISP2's AS.

The components of the layout include:

- The Company AS (AS number 1) is connected to ISP1 and ISP2 through the FortiGate unit.
- The Company has one internal network — the Head Office network at 10.11.101.0/24.
- The FortiGate unit internal interface is on the the Company internal network with an IP address of 10.11.101.110.
- The FortiGate unit external1 interface is connected to ISP1's network with an IP address of 172.20.111.5, an address supplied by the ISP.
- The FortiGate unit external2 interface is connected to IPS2's network with an IP address of 172.20.222.5, an address supplied by the ISP.
- ISP1 AS has an AS number of 650001, and ISP2 has an AS number of 650002.
- Both ISPs are connected to the Internet.
- The ISP1 border router is a neighbor (peer) of the FortiGate unit. It has an address of 172.21.111.4.
- The ISP2 border router is a neighbor (peer) of the FortiGate unit. It has an address of 172.22.222.4.
- Apart from graceful restart, and shorter timers (holdtimer, and keepalive) default settings are to be used whenever possible.

Basic BGP network topology



Assumptions

The basic BGP configuration procedure follows these assumptions:

- ISP1 is the preferred route, and ISP2 is the secondary route
- All basic configuration can be completed in both GUI and CLI
- Only one AS is used for the Company

For these reasons this example configuration does not include:

- Bi-directional forwarding detection (BFD)
- Route maps
- Access lists
- Changing redistribution defaults — make link when example is set up
- IPv6

For more information on these features, see the corresponding section.

Configuring the FortiGate unit

In this topology, the FortiGate unit is the link between the Company Network and the ISP network. The FortiGate unit is the only BGP router on the Company Network, but there is at least one other BGP router on the ISP Network — there may be more but we don't have that information.

As mentioned in the general configuration steps, the ISP must be notified of the Company's BGP router configuration when complete as it will need to add the FortiGate BGP router as a neighbor router on its domain. This step is required for the FortiGate unit to receive BGP routing updates from the ISP network and outside networks.

If the ISP has any special BGP features enabled such as graceful restart, or route dampening that should be determined up front so those features can be enabled on the FortiGate unit.

To configure the FortiGate unit as a BGP router

1. Configure interfaces and default routes
2. Configure firewall services, addresses, and policies
3. Set the FortiGate BGP information
4. Add the internal network to the AS
5. Additional FortiGate BGP configuration

Configure interfaces and default routes

The FortiGate unit is connected to three networks — Company Network on the internal interface, ISP1 Network on external1interface, and ISP2 on external2 interface.

This example uses basic interface settings. Check with your ISP to determine if additional settings are required such as setting the maximum MTU size, or if gateway detection is supported.

High end FortiGate units do not have interfaces labeled Internal, or External. Instead, for clarity's sake, we are using the alias feature to name interfaces for these roles.

Default routes to both external interfaces are configured here as well. Both are needed in case one goes offline. ISP1 is the primary connection and has a smaller administrative distance so it will be preferred over ISP2. Both distances are set low so they will be preferred over any learned routes.

To configure the FortiGate interfaces - web-based manager

1. Go to **System > Network > Interface**.
2. Edit port 1 (internal) interface.
3. Set the following information, and select **OK**.

Alias	internal
IP/Network Mask	10.11.101.110/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Company internal network
Administrative Status	Up

4. Edit port 2 (external1) interface.
5. Set the following information, and select **OK**.

Alias	external1
IP/Network Mask	172.21.111.5/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	ISP1 External BGP network
Administrative Status	Up

6. Edit port 3 (external2) interface.
7. Set the following information, and select **OK**.

Alias	external2
IP/Network Mask	172.22.222.5/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	ISP2 External BGP network
Administrative Status	Up

To configure the FortiGate interfaces - CLI

```
config system interface
   edit port1
      set alias internal
      set ip 10.11.101.110 255.255.255.0
      set allowaccess http https ssh
      set description "Company internal network"
      set status up
   next
   edit port2
      set alias external1
      set ip 172.21.111.5 255.255.255.0
      set allowaccess https ssh
      set description "ISP1 External BGP network"
      set status up
   next
   edit port3
      set alias external2
      set ip 172.22.222.5 255.255.255.0
      set allowaccess https ssh
      set description "ISP2 External BGP network"
      set status up
   next
end
```

To configure default routes for both ISPs - web-based manager

1. Go to **Router > Static > Static Routes**.
2. Delete any existing routes with a IP/Mask of address of 0.0.0.0/0.0.0.0
3. Select **Create New**, and set the following information.

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port2
Gateway	172.21.111.5
Distance	10

4. Select **OK**.
5. Select **Create New**, and set the following information.

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port3
Gateway	172.22.222.5
Distance	15

6. Select **OK**.

To configure default routes for both ISPs - CLI

```
config router static
   edit 1
      set device "port2"
      set distance 10
      set gateway 172.21.111.5
   next
   edit 2
      set device "port3"
      set distance 15
      set gateway 172.22.222.5
   next
end
```

Configure firewall services, addresses, and policies

To create the security policies, first you must create the firewall services group that will include all the services that will be allowed, then you must define the addresses that will be used in the security policies, and lastly you configure the security policies themselves.

To keep the configuration simple, the Company is allowing only HTTP traffic out of the local network. This will allow employees access to the Internet and their web-mail. DNS services will also be allowed through the firewall.

The security policies will allow HTTP traffic (port 80 and port 8080), HTTPS traffic (port 443), FTP traffic (port 21), and DNS traffic (port 53 and port 953) in both directions. Also BGP (port 179) may need access through the firewall.

For added security, you may want to define a smaller range of addresses for the internal network. For example if only 20 addresses are used, only allow those addresses in the range.

In the interest of keeping things simple, a zone will be used to group the two ISP interfaces together. This will allow using one security policy to apply to both ISPs at the same time. Remember to block intra-zone traffic as this will help prevent one ISP sending traffic to the other ISP through your FortiGate unit using your bandwidth. The zone keeps configuration simple, and in the future if there is a need for separate policies for each ISP, they can be created and the zone can be deleted.

The addresses that will be used are the addresses of the FortiGate unit internal and external ports, and the internal network.

More policies or services can be added in the future as applications are added to the network. For more information on security policies, see the firewall chapter of the FortiGate Administration Guide.

When configuring security policies always enable logging to help you track and debug your traffic flow.

To create a firewall services group - web-based manager

1. Go to **Policy & Objects > Services**, select the dropdown arrow next to **Create New** and select **Service Group**.
2. For **Group Name**, enter “Basic_Services”.
3. From the **Members** dropdown, choose the following six services — BGP, FTP, FTP_GET, FTP_PUT, DNS, HTTP, and HTTPS.
4. Select **OK**.

To create a firewall services group - CLI

```
config firewall service group
   edit "Basic_Services"
      set member "BGP" "DNS" "FTP" "FTP_GET" "FTP_PUT" "HTTP" "HTTPS"
   next
end
```

To create a zone for the ISP interfaces - web-based manager

1. Go to **Network > Interfaces.**
2. Select the caret to the right of **Create New** and then select **Zone**.
3. Enter the following information.

Zone Name	ISPs
Block Intra-zone traffic	enable
interface members	port2 port3

4. Select **OK**.

To create a zone for the ISP interfaces - CLI

```
config system zone
   edit "ISPs"
      set interface "port2" "port3"
      set intrazone block
   next
end
```

To add the firewall addresses - web-based manager

1. Go to **Policy & Objects > Addresses**.
2. Select **Create New**, and set the following information.

Category	Address
Name	Internal_network
Type	Subnet / IP Range
Subnet / IP Range	10.11.101.0 255.255.255.0
Interface	port1

3. Select **OK**.

To add the firewall addresses - CLI

```
config firewall address
   edit "Internal_network"
      set associated-interface "port1"
      set subnet 10.11.101.0 255.255.255.0
   next
end
```

To add the HTTP and DNS security policies - web-based manager

1. Go to **Policy & Objects > IPv4 Policy**, and select **Create New**.
2. Set the following information.

Incoming Interface	port1(internal)
Source Address	Internal_network
Outgoing Interface	ISPs
Destination Address	All
Schedule	Always
Service	Basic_services
Action	ACCEPT

Log Allowed Traffic	Enable
Firewall / Network Options	Enable NAT
Comments	ISP1 basic services out policy

3. Select **OK**.
4. Select **Create New**, and set the following information.

Incoming Interface	ISPs
Source Address	All
Outgoing Interface	port1(internal)
Destination Address	Internal_network
Schedule	Always
Service	Basic_services
Action	ACCEPT
Log Allowed Traffic	Enable
Firewall / Network Options	Enable NAT
Comments	ISP1 basic services in policy

To add the security policies - CLI

```
config firewall policy
   edit 1
      set srcintf "port1"
      set srcaddr "Internal_network"
      set dstintf "ISPs"
      set dstaddr "all"
      set schedule "always"
      set service "Basic_services"
      set action accept
      set nat enable
      set profile-status enable
      set logtraffic enable
      set comments "ISP1 basic services out policy"
   next
   edit 2
      set srcintf "ISPs"
      set srcaddr "all"
      set dstintf "port1"
      set dstaddr "Internal_network"
      set schedule "always"
      set service "Basic_services"
      set action accept
      set nat enable
      set profile-status enable
      set logtraffic enable
```

```
      set comments "ISP1 basic services in policy"
   next
end
```

Set the FortiGate BGP information

When using the default information, there are only two fields to set to configure the FortiGate unit as a BGP router.

For this configuration the FortiGate unit will be in a stub area with one route out — the ISP BGP router. Until you configure the ISP router as a neighbor, even that route out is not available. So while after this part of the configuration is complete your FortiGate unit will be running BGP, it won't know about any other routers running BGP until the next part of the configuration is complete.

To set the BGP router information - web-based mananger

1. Go to **Network > BGP**.
2. Set the following information, and select **OK**.

Local As	1
Router ID	10.11.101.110

To set the BGP router information - CLI

```
config router BGP
   set as 1
   set router-id 10.11.101.110
end
```

Add the internal network to the AS

The Company is one AS with the FortiGate unit configured as the BGP border router connecting that AS to the two ISPs ASes. The internal network in the Company's AS must be defined. If there were other networks in the company such as regional offices, they would be added here as well.

To set the networks in the AS - web-based manager

1. Go to **Network > BGP**.
2. In **Networks**, next to **IP/Netmask**, set the following information and select **Add**.

IP/Netmask	10.11.101.0/255.255.255.0

To set the networks in the AS - CLI

```
config router bgp
   config network
   edit 1
      set prefix 10.11.101.0 255.255.255.0
   next
   end
end
```

Add BGP neighbor information

The configuration will not work unless you set **Remote AS** neighbors. This can be done in either the web-based manager or the CLI.

To configure the BGP neighbors - web-based manager

1. Go to **Network > BGP**.
2. Add a **Neighbors IP** of 172.21.111.4 with the **Remote AS** set to 650001, then click **Add/Edit**.
3. Add another **Neighbors IP** of 172.22.222.4 with the **Remote AS** set to 650002, then click **Add/Edit**.

To configure the BGP neighbors - CLI

```
config router BGP
   set as 1
      config neighbor
         edit "172.21.111.4"
            set remote-as 650001
         next
         edit "172.22.222.4"
            set remote-as 650002
         next
      end
   end
```

Additional FortiGate BGP configuration

At this point that is all the settings that can be done in both the web-based manger and the CLI. The remaining configuration must be completed in the CLI.

These additional settings are mainly determined by your ISP requirements. They will determine your timers such as keep alive timers, if extended features like BFD and graceful restart are being used, and so on. For this example, some common simply features are being used to promote faster detections of network failures which will result in better service for the Company's internal network users.

The ISPs do not require authentication between peer routers.

These commands will enable or modify the following features on the FortiGate unit, and where possible on neighboring routers as well:

- `bestpath-med-missing-as-worst` — treats a route without an MED as the worst possible available route due to expected unreliability
- `fast-external-failover` — immediately reset the session information associated with BGP external peers if the link used to reach them goes down
- `graceful-restart*` — advertise reboots to neighbors so they do not see the router as offline, wait before declaring them offline, and how long to wait when they reboot before advertising updates. These commands applies to neighbors and are part of the BGP capabilities. This prevents unneeded routing updates.
- `holdtime-timer` — how long the router will wait for a keepalive message before declaring a router offline. A shorter time will find an offline router faster.
- `keepalive-timer` — how often the router sends out keepalive messages to neighbor routers to maintain those sessions.
- `log-neighbor-changes` — log changes to neighbor routers' status. This can be useful for troubleshooting from both internal and external networks.

- `connect-timer` — how long in seconds the FortiGate unit will try to reach this neighbor before declaring it offline.
- `weight` — used to prefer routes from one neighbor over the other. In this example ISP1 is the primary connection so it is weighted higher than ISP2

To configure additional BGP options - CLI

```
config router bgp
   set bestpath-med-missing-as-worst enable
   set fast-external-failover enable
   set graceful-restart enable
   set graceful-restart-time 120
   set graceful-stalepath-time 180
   set graceful-update-delay 180
   set holdtime-timer 120
   set keepalive-timer 45
   set log-neighbor-changes enable
   config neighbor
      edit 172.21.111.4
         set connect-timer 60
         set description "ISP1"
         set holdtime-timer 120
         set keepalive-timer 45
         set weight 250
      next
      edit 172.22.222.4
         set connect-timer 60
         set description "ISP2"
         set holdtime-timer 120
         set keepalive-timer 45
         set weight 100
      next
   end
end
```

Configuring other networking devices

There are two other networking devices that need to be configured: both ISPs' BGP routers.

The ISPs' routers must add the FortiGate unit as a neighbor so route updates can be sent in both directions. Note that ISP1 is not directly connected to ISP2 that we are aware of.

Inform both of your ISPs of your FortiGate unit's BGP information. Once they have configured their router, you can test your BGP connection to the Internet.

They will require your FortiGate unit's:

- IP address of the connected interface
- The router ID
- Your Company's AS number

Testing this configuration

With the dual-homed BGP configuration in place, you should be able to send and receive traffic, send and receive routes, and not have any routing loops. Testing the networks will confirm things are working as expected.

In general for routing you need to look at the routing table on different routers to see what routes are being installed. You also need to sniff packets to see how traffic is being routed in real time. These two sources of information will normally tell you what you need to know.

Testing of this example's network configuration should be completed in two parts:

- Testing network connectivity
- Verifying the FortiGate unit's routing tables
- Verifying traffic routing
- Verifying the dual-homed side of the configuration

Testing network connectivity

A common first step in testing a new network topology is to test if you can reach the Internet and other locations as you expect you should. If not, you may be prevented be cabling issues, software or other issues.

The easiest way to test connections is to use ping, once you ensure that all the FortiGate unit's interfaces and ISP routers have ping support enabled. Also ensure that the security policies allow ping through the firewall.

Connections to test in this example are the internal network to ISP1's router or the Internet, and the same for ISP2. If you can connect on the external side of the Fortinet unit, try to ping the internal network. Those three tests should prove your basic network connections are working.

Once you have completed testing the network connectivity, turn off ping support on the external interfaces for additional security.

Verifying the FortiGate unit's routing tables

The FortiGate routing table contains the routes stored for future use. If you are expecting certain routes to be there and they are not, that is a good indicator that your configuration is not what you expected.

The CLI command `get router info routing-table details` will provide you with every route's routing protocol, destination address, gateway address, interface, weighting, and if the address is directly connected or not.

If you want to limit the display to BGP routes only, use the CLI command `get router info routing-table bgp`. If there are no BGP routes in the routing table, nothing will be displayed. In the CLI command you can replace BGP with static, or other routing protocols to only display those routes.

If you want to see the contents of the routing information database (RIB), use the CLI command `get router info routing-table database`. This will display the incoming routes that may or may not make it into the routing table.

Verifying traffic routing

Traffic may be reaching the internal network, but it may be using a different route than you think to get there.

Use a browser to try and access the Internet.

If needed, allow traceroute and other diag ports to be opened until things are working properly. Then remove access for them again.

Look for slow hops on the traceroute, or pings to a location, as they may indicate network loops that need to be fixed.

Any locations that have an unresolved traceroute or ping must be examined and fixed.

Use network packet sniffing to ensure traffic is being routed as you expect.

Verifying the dual-homed side of the configuration

Since there are two connections to the Internet in this example, theoretically you can pull the plug on one of the ISP connections, and all traffic will go through the other connection. Alternately, you may choose to remove a default route to one ISP, remove that ISP's neighbor settings, or change the weightings to prefer other other ISP. These alternate ways to test dual-homing do not change physical cabling, which may be preferred in some situations.

If this does not work as expected, things to check include:

- Default static routes — If these are wrong or don't exist, the traffic can't get out.
- BGP neighbor information — If the ISP router information is incorrect, the FortiGate unit won't be able to talk to it.

Redistributing and blocking routes in BGP

During normal BGP operation, peer routers redistribute routes from each other. However, in some specific situations it may be best to not advertise routes from one peer, such as if the peer is redundant with another peer (they share the same routes exactly), if it might be unreliable in some way, or some other reason. The FortiGate can also take routes it learns from other protocols and advertise them in BGP, for example OSPF or RIP. If your Company hosts its own web or email servers, external locations will require routes to your networks to reach those services.

In this example the Company has an internal network in an OSPF area, and is connected to a BGP AS and two BGP peers. Company goes through these two peers to reach the Internet. However, Peer 1 routes will not be advertised to Peer 2. The Company internal user and server networks are running OSPF, and will redistribute those routes to BGP so external locations can reach the web and email servers.

This section includes the following topics:

- Network layout and assumptions
- Configuring the FortiGate unit
- Testing network configuration

Network layout and assumptions

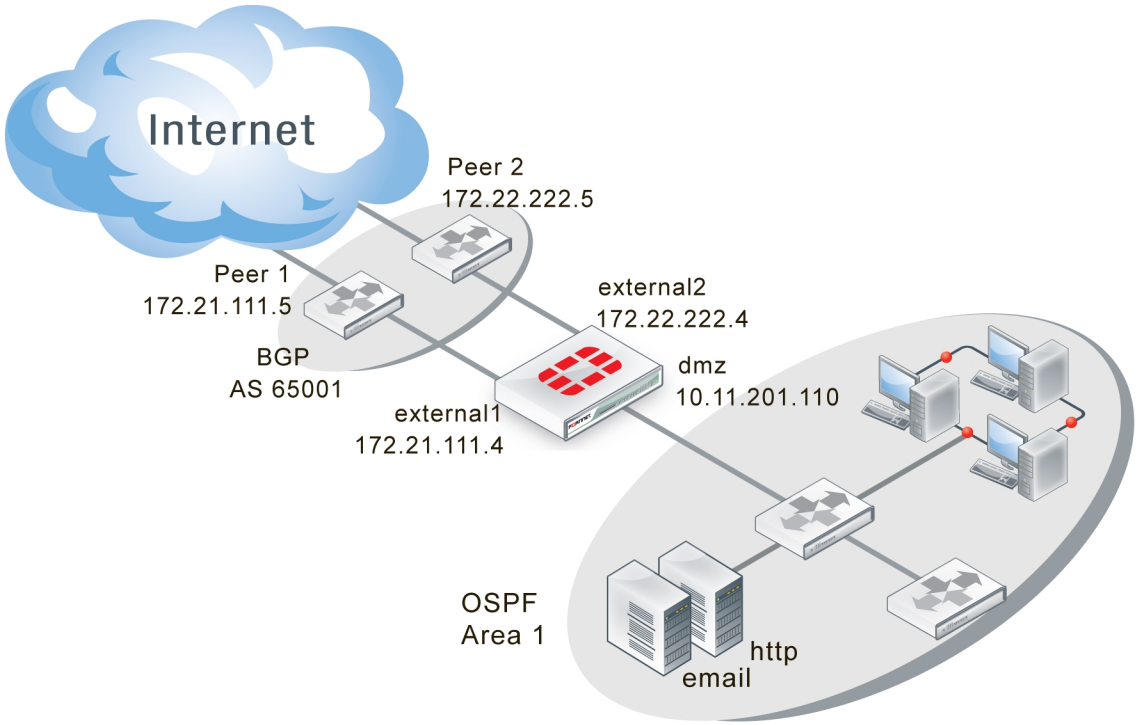
The network layout for the BGP redistributing routes example involves the company network being connected to two BGP peers as shown below. In this configuration the FortiGate unit is the BGP border router between the Company AS, and the peer routers.

The components of the layout include:

- There is only one BGP AS in this example — AS 65001, shared by the FortiGate unit and both peers.
- The Company's FortiGate unit connects to the Internet through two BGP peers.
- The Company internal networks on the dmz interface of the FortiGate unit with an IP of 10.11.201.0/24.
- The FortiGate units' interfaces are connected as follows:

  - port1 (dmz) has IP 10.11.201.110 and is the internal user and server network
  - port2 (external1) has IP 172.21.111.4 and is connected to Peer 1's network
  - port3 (external2) has IP 172.22.222.4 and is connected to Peer 2's network
- Peer 1 has IP 172.21.111.5, and Peer 2 has IP 172.22.222.5.
- OSPF Area 1 is configured on the dmz interface of the FortiGate unit, and is the routing protocol used by the internal users and servers.

BGP network topology



Assumptions

The the BGP redistributing routes configuration procedure follows these assumptions:

- The FortiGate unit has been configured following the Install Guide
- Interfaces port1, port2, and port 3 exist on the FortiGate unit
- We don't know the router manufacturers of Peer 1 and Peer 2
- We don't know what other devices are on the BGP AS or OSPF Area
- All basic configuration can be completed in both GUI and CLI
- Access lists and route maps will only be configured in CLI
- VDOMs are not enabled on the FortiGate unit

Configuring the FortiGate unit

1. Configuring the FortiGate unit — networks and firewalls
2. Configuring the FortiGate unit - BGP
3. Configuring the FortiGate unit - OSPF

4. Configuring other networking devices
5. Configuring ECMP support for BGP

Configuring the FortiGate unit — networks and firewalls

The FortiGate unit has three interfaces connected to networks — two external and one dmz.

Security policies must be in place to allow traffic to flow between these networks.

Firewall services will change depending on which routing protocol is being used on that network — either BGP or OSPF. Beyond that, all services that are allowed will be allowed in both directions due to the internal servers. The services allowed are web-server services (DNS, HTTP, HTTPS, SSH, NTP, FTP*, SYSLOG, and MYSQL), email services (POP3, IMAP, and SMTP), and general troubleshooting services (PING, TRACEROUTE). Those last two can be removed once the network is up and working properly to increase security. Other services can be added later as needed.

To configure the interfaces - GUI

1. Go to **Network > Interfaces**.
2. Edit port1 (dmz) interface.
3. Set the following information, and select **OK**.

Alias	dmz
IP/Network Mask	10.11.201.110/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	OSPF internal networks
Administrative Status	Up

4. Edit port2 (external1) interface.
5. Set the following information, and select **OK**.

Alias	external1
IP/Network Mask	172.21.111.4/255.255.255.0
Administrative Access	HTTPS SSH
Description	BGP external Peer 1
Administrative Status	Up

6. Edit port3 (external2) interface.
7. Set the following information, and select **OK**.

Alias	external2
IP/Network Mask	172.22.222.4/255.255.255.0

Administrative Access	HTTPS SSH
Description	BGP external2 Peer2
Administrative Status	Up

To configure the FortiGate interfaces (CLI)

```
config system interface
   edit port1
      set alias dmz
      set ip 10.11.201.110 255.255.255.0
      set allowaccess https ssh ping
      set description "OSPF internal networks"
      set status up
   next
   edit port2
      set alias external1
      set ip 172.21.111.5 255.255.255.0
      set allowaccess https ssh
      set description "external1 Peer 1"
      set status up
   next
   edit port3
      set alias external2
      set ip 172.22.222.5 255.255.255.0
      set allowaccess https ssh
      set description "external2 Peer 2"
      set status up
   next
end
```

To configure the firewall addresses - GUI

1. Go to **Policy & Objects > Addresses**.
2. Select **Create New**, and set the following information.

Category	Address
Name	BGP_services
Type	Subnet / IP Range
Subnet / IP Range	10.11.201.0 255.255.255.0
Interface	port1

3. Select **OK**.

To configure the firewall addresses - CLI

```
config firewall address
   edit "BGP_services"
      set associated-interface "port1"
      set subnet 10.11.201.0 255.255.255.0
```

```
    next
end
```

To configure firewall service groups - GUI

1. Go to **Policy & Objects > Services.** Under the **Create New** dropdown menu, select **Service Group**.
2. Name the group BGP_Services.
3. Add the following services to the **Members** list: BGP, DNS, FTP, FTP_GET, FTP_PUT, HTTP, HTTPS, IMAP, MYSQL, NTP, PING, POP3, SMTP, SSH, SYSLOG, and TRACEROUTE.
4. Select **OK**.
5. Create another new **Service Group**.
6. Name the group OSPF_Services.
7. Add the following services to the *Members* list: DNS, FTP, FTP_GET, FTP_PUT, HTTP, HTTPS, IMAP, MYSQL, NTP, OSPF, PING, POP3, SMTP, SSH, SYSLOG, and TRACEROUTE.
8. Select **OK**.

To configure firewall service groups - CLI

```
config firewall service group
   edit "BGP_services"
      set member "BGP", "DHCP" "DNS" "FTP" "FTP_GET" "FTP_PUT" "HTTP" "HTTPS" "IMAP"
          "MYSQL" "NTP" "PING" "POP3" "SMTP" "SSH" "TRACEROUTE" "SYSLOG"
   next
   edit "OSPF_services"
      set member "DHCP" "DNS" "FTP" "FTP_GET" "FTP_PUT" "HTTP" "HTTPS" "IMAP" "MYSQL"
          "NTP" "PING" "POP3" "SMTP" "SSH" "TRACEROUTE" "SYSLOG" "OSPF"
   next
end
```

Configuring the FortiGate unit - BGP

The only change from the standard BGP configuration for this example is configuring the blocking Peer 1's routes from being advertised to Peer 2. From the network topology you can guess that both of these peers likely share many routes in common and it makes no sense to advertise unneeded routes.

Blocking Peer 1's routes to Peer 2 is done with distribute-list-out keyword. They allow you to select which routes you will advertise to a neighbor using an access list. In this case we will block all incoming routes from Peer 1 when we send updates to Peer 2. Otherwise Peer 1 and Peer 2 are regular neighbors.

The FortiGate unit will redistribute routes learned from OSPF into BGP.

This is advanced configuration and the commands are only available in the CLI.

To create access list to block Peer 1 - CLI

```
config access-list
   edit "block_peer1"
      config rule
      edit 1
         set prefix 172.21.111.0 255.255.255.0
         set action deny
         set exact-match enable
      end
   end
```

```
end
```

To configure BGP on the FortiGate unit - CLI

```
config router bgp
   set as 65001
      set router-id 10.11.201.110
      config redistribute ospf
         set status enable
      end
      config neighbor
      edit 172.22.222.5
         set remote-as 65001
         set distribute-list-out "block_peer1"
      next
      edit 172.21.111.5
         set remote-as 65001
      end
   end
```

Configuring the FortiGate unit - OSPF

This configuration involves only one OSPF Area, so all traffic will be intra-area. If there were two or more areas with traffic going between them it would be inter-area traffic. These two types are comparable to BGP's traffic within one AS (iBGP) or between multiple ASes (eBPG). Redistributing routes from OSPF to BGP is considered external because either the start or end point is a different routing protocol.

The OSPF configuration is basic apart from redistributing BGP routes learned.

To configure OSPF on the FortiGate unit - web-based manager

1. Go to **Network > OSPF**.
2. For Router ID enter `10.11.201.110` and then select **Apply**.
3. Under **Advanced Options** > **Redistribute**, select **BGP** and set the BGP **Metric** to 1.
4. For **Areas**, select **Create New,** enter the following information and then select **OK**.

Area (IP)	`0.0.0.0`
Type	Regular
Authentication	None

5. For **Networks**, select **Create New**.
6. Enter 10.11.201.0/255.255.255.0 for **IP/Netmask**, and select **OK**.
7. For **Interfaces**, select **Create New**.
8. Enter `OSPF_dmz_network` for **Name**.
9. Select `port1(dmz)` for **Interface**, and then select **OK**.

To configure OSPF on the FortiGate unit - CLI

```
config router ospf
   set router-id 10.11.201.110
   config area
```

```
      edit 0.0.0.0
         set type regular
         set authentication none
      end
   config network
      edit 1
         set area 0.0.0.0
         set prefix 10.11.201.0 255.255.255.0
      end
   config interface
      edit "OSPF_dmz_network"
         set interface port1(dmz)
         set status enable
      end
   config redistribute bgp
      set status enable
      set metric 1
   end
end
```

Configuring other networking devices

As with all BGP configurations, the peer routers will need to be updated with the FortiGate unit's BGP information including IP address, AS number, and what capabilities are being used such as IPv6, graceful restart, BFD, and so on.

Configuring ECMP support for BGP

"ECMP" stands for "Equal Cost Multiple Path". ECMP is a mechanism that allows multiple routes to the same destination with different next-hops and load-balances routed traffic over those multiple next-hops.

- ECMP only works for routes that are sourced by the same routing protocol (that is: Static Routes, OSPF, or BGP).
- ECMP is enabled by default with 10 paths.
- ECMP with static routes is effective if the routes are configured with the same distance and same priority.

To configure ECMP support - CLI

```
config router bgp
   set ebgp-multipath disable[|enable]
   set ibgp-multipath disable[|enable]
   ...
end
```

Testing network configuration

Testing this configuration involves the standard connectivity checks, but also ensuring that routes are being passed between protocols as expected.

Check the routing table on the FortiGate unit to ensure that routes from both OSPF and BGP are present.

Check the routing table on devices on the OSPF network for routes redistributed from BGP. Also check those devices for connectivity to the Internet.

Check the routing table on Peer 2 to ensure no routes from Peer 1 are present, but routes from the internal OSPF network are present.

For help with troubleshooting, see Redistributing and blocking routes in BGP on page 456.

Open Shortest Path First (OSPF)

This section describes OSPF routing.

The following topics are included in this section:

OSPF Background and concepts

OSPF (Open Shortest Path First) is a link-state interior routing protocol, that is widely used in large enterprise organizations. It only routes packets within a single autonomous system (AS). This is different from BGP as BGP can communicate between ASes.

This section includes:

- Background
- The parts and terminology of OSPF
- How OSPF works

Background

OSPF version 2 was defined in 1998 in RFC 2328. OSPF was designed to support classless IP addressing, and variable subnet masks. This was a shortcoming of the earlier RIP protocols.

Updates to OSPF version 2 are included in OSPF version 3 defined in 2008 in RFC 5340. OSPF3 includes support for IPv6 addressing where previously OSPF2 only supports IPv4 addressing.

The main benefit of OSPF is that it detects link failures in the network quickly and within seconds has converged network traffic successfully without any networking loops. Also OSPF has many features to control which routes are propagated and which are not, maintaining smaller routing tables. OSPF can also provide better load-balancing on external links than other interior routing protocols.

The parts and terminology of OSPF

Parts and terminology of OSPF includes:

- OSPFv3 and IPv6
- Router ID
- Adjacency
- Designated router (DR) and backup router (BDR)
- Area
- Authentication
- Hello and dead intervals
- Access Lists

OSPFv3 and IPv6

OSPFv3 (OSPF version 3) includes support for IPv6. Generally, all IP addresses are in IPv6 format instead of IPv4. However, OSPFv3 area numbers use the same 32-bit numbering system as OSPFv2, as described in RFC 2740. Likewise, the router ID and area ID are in the same format as OSPFv2.

As with most advanced routing features on your FortiGate unit, IPv6 settings for dynamic routing protocols must be enabled before they will be visible in the GUI. To enable IPv6 configuration in the GUI, enable it in **System > Config > Features**.

For IPv6, the main difference in OSPFv3 is that, rather than using a network statement to enable OSPFv3 on an interface, you define OSPF6 (OSPF for IPv6) interfaces, which are bound to interface and area. This configuration must be done in the CLI, as follows (with sample interfaces and addresses):

```
config router ospf6
   config area
      edit 0.0.0.0
   next
end
config ospf6-interface
   edit "tunnel"
   set interface "to_FGT300A-7"
next
   edit "internal_lan"
   set interface "port1"
next
   set router-id 10.174.0.113
end
```

Note that OSPFv3 neighbors use link-local IPv6 addresses, but with broadcast and point-to-point network types, neighbors are automatically discovered. You only have to manually configure neighbors when using non-broadcast network types.

Router ID

In OSPF, each router has a unique 32-bit number called its Router ID. Often this 32-bit number is written the same as a 32-bit IPv4 address would be written in dotted decimal notation. However some brands of routers, such as Cisco routers, support a router ID entered as an integer instead of an IP address.

It is a good idea to not use IP address in use on the router for the router ID number. The router ID does not have to be a particular IP address on the router. By choosing a different number, it will be harder to get confused which number you are looking at. A good idea can be to use the as much of the area's number as possible. For example if you have 15 routers in area 0.0.0.0 they could be numbered from 0.0.0.1 to 0.0.0.15. If you have an area 1.1.1.1, then routers in that area could start at 1.1.1.10 for example.

You can manually set the router ID on your FortiGate unit.

To manually set an OSPF router ID of 0.0.1.1 - web-based manager

1. Go to **Network > OSPF**.
2. For **Router ID**, enter `0.0.1.1`.
3. Select **Apply**.

To manually set an OSPF router ID of 0.0.1.1 - CLI

```
config router ospf
   set router-id 0.0.1.1
end
```

Adjacency

In an OSPF routing network, when an OSPF router boots up it sends out OSPF Hello packets to find any neighbors, routers that have access to the same network as the router booting up. Once neighbors are discovered and Hello packets are exchanged, updates are sent, and the Link State databases of both neighbors are synchronized. At this point these neighbors are said to be adjacent.

For two OSPF routers to become neighbors, the following conditions must be met.

- The subnet mask used on both routers must be the same subnet.
- The subnet number derived using the subnet mask and each router's interface IP address must match.
- The Hello interval & The Dead interval must match.
- The routers must have the same OSPF area ID. If they are in different areas, they are not neighbors.
- If authentication is used, they must pass authentication checks.

If any of these parameters are different between the two routers, the routers do not become OSPF neighbors and cannot be adjacent. If the routers become neighbors, they are adjacent.

Adjacency and neighbors

Neighbor routers can be in a Two-Way state, and not be adjacent. Adjacent routers normally have a neighbor state of FULL. Neighbors only exchange Hello packets, and do not exchange routing updates. Adjacent routers exchange LSAs (LSDB information) as well as Hello packets. A good example of an adjacent pair of routers is the DR and BDR.

You can check on the state of an OSPF neighbor using the CLI command `get router info ospf neighbor all`. See OSPF Background and concepts on page 463.

Why adjacency is important

It is important to have adjacent pairs of routers in the OSPF routing domain because routing protocol packets are only passed between adjacent routers. This means adjacency is required for two OSPF routers to exchange routes.

If there is no adjacency between two routers, such as one on the 172.20.120.0 network and another on the 10.11.101.0 network, the routers do not exchange routes. This makes sense because if all OSPF routers on the OSPF domain exchanged updates it would flood the network.

Also, it is better for updates to progress through adjacent routers to ensure there are no outages along the way. Otherwise, updates could skip over routers that are potentially offline, causing longer routing outages and delays while the OSPF domain learns of this outage later on.

If the OSPF network has multiple border routers and multiple connections to external networks, the designated router (DR) determines which router pairs become adjacent. The DR can accomplish this because it maintains the complete topology of the OSPF domain, including which router pairs are adjacent.

The BDR also has this information in case the DR goes offline.

Designated router (DR) and backup router (BDR)

In OSPF a router can have a number of different roles to play.

A designated router (DR) is the designated broadcasting router interface for an AS. It looks after all the initial contact and other routing administration traffic. Having only one router do all this greatly reduces the network traffic and collisions.

If something happens and the designated router goes offline, the backup designated router (BDR) takes over. An OSPF FortiGate unit interface can become either a DR or BDR. Both the DR and the BDR cover the same area, and are elected at the same time. The election process doesn't have many rules, but the exceptions can become complex.

Benefits

The OSPF concept of the designated router is a big step above RIP. With all RIP routers doing their own updates all the time, RIP suffers from frequent and sometimes unnecessary updates that can slow down your network. With OSPF, not only do routing changes only happen when a link-state changes instead of any tiny change to the routing table, but the designated router reduces this overhead traffic even more.

However, smaller network topologies may only have a couple routers besides the designated router. This may seem excessive, but it maintains the proper OSPF form and it will still reduce the administration traffic but to a lesser extent than on a large network. Also, your network topology will be ready whenever you choose to expand your network.

DR and BDR election

An election chooses the DR and BDR from all the available routers. The election is primarily based on the priority setting of the routers—the highest priority becomes the DR, and the second highest becomes BDR. To resolve any ties, the router with the highest router ID wins. For example 192.168.0.1 would win over 10.1.1.2.

The router priority can vary from 0 to 255, but at 0 a router will never become a DR or BDR. If a router with a higher priority comes on line after the election, it must wait until after the DR and BDR go offline before it would become the DR.

If the original DR goes offline, but then is available when the BDR goes offline later on, the original DR will be promoted back to DR without an election leaving the new BDR as it is.

With your FortiGate unit, to configure the port1 interface to be a potential OSPF designated router or backup designed router called `ospf_DR` on the network, you need to raise the priority of the router to a very high number such as 250 out of 255. This will ensure the interface has a chance to be a DR, but will not guarantee that it will be one. Give the interface a low numbered IP address—such as 10.1.1.1 instead of 192.168.1.1—to help ensure it becomes a DR, but that is not part of this example. Enter the following command:

```
config router ospf
   config ospf-interface
   edit "ospf_DR"
      set priority 250
   end
end
```

Area

An OSPF area is a smaller part of the larger OSPF AS. Areas are used to limit the link-state updates that are sent out. The flooding used for these updates would overwhelm a large network, so it is divided into these smaller areas for manageability.

Within an area if there are two or more routers that are viable, there will always be a designated router (DR) and a backup DR (BDR). For more on these router roles, see Designated router (DR) and backup router (BDR) on page 465.

Defining a private OSPF area, involves:

- Assigning a 32-bit number to the area that is unique on your network
- Defining the characteristics of one or more OSPF areas
- Creating associations between the OSPF areas that you defined and the local networks to include in the OSPF area
- If required, adjusting the settings of OSPF-enabled interfaces.

IPv6 OSPF area numbers use the same 32-bit number notation as IPv4 OSPF.

If you are using the web-based manager to perform these tasks, follow the procedures summarized below.

FortiGate units support the four main types of OSPF area:

- Backbone area
- Stub area
- NSSA
- Regular area

Backbone area

Every OSPF network has at least one AS, and every OSPF network has a backbone area. The backbone is the main area, or possibly the only area. All other OSPF areas are connected to a backbone area. This means if two areas want to pass routing information back and forth, that routing information will go through the backbone on its way between those areas. For this reason the backbone not only has to connect to all other areas in the network, but also be uninterrupted to be able to pass traffic to all points of the network.

The backbone area is referred to as area 0 because it has an IP address of 0.0.0.0.

Stub area

A stub area is an OSPF area that receives no outside routes advertised into it, and all routing in it is based on a default route. This essentially isolates it from outside areas.

Stub areas are useful for small networks that are part of a larger organization, especially if the networking equipment can't handle routing large amounts of traffic passing through, or there are other reasons to prevent outside traffic, such as security. For example most organizations don't want their accounting department to be the center of their network with everyone's traffic passing through there. It would increase the security risks, slow down their network, and it generally doesn't make sense.

A variation on the stub area is the totally stubby area. It is a stub area that does not allow summarized routes.

NSSA

A not-so-stubby-area (NSSA) is a stub area that allows for external routes to be injected into it. While it still does not allow routes from external areas, it is not limited to only using he default route for internal routing.

Regular area

A regular area is what all the other ASes are, all the non-backbone, non-stub, non-NSSA areas. A regular area generally has a connection to the backbone, does receive advertisements of outside routes, and does not have an area number of 0.0.0.0.

Authentication

In the OSPF packet header are two authentication related fields —AuType, and Authentication.

All OSPF packet traffic is authenticated. Multiple types of authentication are supported in OSPFv2. However in OSPFv3, there is no authentication built-in but it is assumed that IPsec will be used for authentication instead.

Packets that fail authentication are discarded.

Null authentication

Null authentication indicates there is no authentication being used. In this case the 16-byte Authentication field is not checked, and can be any value. However checksumming is still used to locate errors. On your FortiGate this is the `none` option for authentication.

Simple Password authentication

Simple password refers to a standard plain text string of characters. The same password is used for all transactions on a network. The main use of this type of authentication is to prevent routers from accidently joining the network. Simple password authentication is vulnerable to many forms of attack, and is not recommended as a secure form of authentication.

Cryptographic authentication

Cryptographic authentication involves the use of a shared secret key to authenticate all router traffic on a network. The key is never sent over the network in the clear—a packet is sent and a condensed and encrypted form of the packet is appended to the end of the packet. A non-repeating sequence number is included in the OSPF packet to protect against replay attacks that could try to use already sent packets to disrupt the network. When a packet is accepted as authentic the authentication sequence number is set to the packet sequence number. If a replay attack is attempted, the packet sent will be out of sequence and ignored.

Your FortiGate unit supports all three levels of authentication through the authentication keyword associated with creating an OSPF interface .

For example to create an OSPF interface called `Accounting` on the port1 interface that is a broadcast interface, has a hello interval of 10 seconds, has a dead interval of 40 seconds, uses text authentication (simple password) with a password of “ospf_test”, enter the command:

```
config router ospf
   config ospf-interface
   edit Accounting
      set interface port1
      set network-type broadcast
      set hello-interval 10
      set dead-interval 40
      set authentication text
      set authentication-key "ospf_test"
   end
end
```

Hello and dead intervals

The OSPF Hello protocol is used to discover and maintain communications with neighboring routers.

Hello packets are sent out at a regular interval for this purpose. The DR sends out the Hello packets. In a broadcast network, the multicast address of 224.0.0.5 is used to send out Hello packets. New routers on the network listen for and reply to these packets to join the OSPF area. If a new router never receives a Hello packet, other routers will not know it is there and will not communicate with it. However, once a new router is discovered the DR adds it to the list of routers in that area and it is integrated into the routing calculations.

Dead interval is the time other routers will wait before declaring a neighbor dead (offline). Setting a reasonable dead interval is very important. If this interval is too short, routers will be declared offline when they are just slow or momentarily inaccessible, and link-state updates will happen more than they need to, using more bandwidth. If the dead interval is too long, it will slow down network traffic overall if online routers attempt to contact offline ones instead of re-routing traffic.

FortiOS also supports OSPF fast-hello, which provides a way of sending multiple Hello packets per second. This is achieved by setting a dead-interval to one second. The hello-multiplier, which can be any number between 4 and 10, determines the number of Hello packets that will be sent every second. The CLI syntax for OSPF fast-hello follows:

```
config ospf-interface
   edit ospf1
      set interface port1
      set network-type broadcast
      set dead-interval 1
      set hello-multiplier 4
end
```

Access Lists

Access lists are filters used by FortiGate unit OSPF routing. An access list provides a list of IP addresses and the action to take for them — essentially an access list makes it easy to group addresses that will be treated the same into the same group, independent of their subnets or other matching qualities. You add a rule for each address or subnet that you want to include, specifying the action to take for it. For example if you wanted all traffic from one department to be routed a particular way, even in different buildings, you can add all the addresses to an access list and then handle that list all at once.

Each rule in an access list consists of a prefix (IP address and netmask), the action to take for this prefix (permit or deny), and whether to match the prefix exactly or to match the prefix and any more specific prefix.

The FortiGate unit attempts to match a packet against the rules in an access list starting at the top of the list. If it finds a match for the prefix, it takes the action specified for that prefix. If no match is found the default action is deny.

Access lists greatly speed up configuration and network management. When there is a problem, you can check each list instead of individual addresses. Also, it eases troubleshooting since if all addresses on one list have problems, it eliminates many possible causes right away.

If you are using the OSPF+ IPv6 protocols you will need to use access-list6, the IPv6 version of access list. The only difference is that access-list6 uses IPv6 addresses.

For example, if you want to create an access list called `test_list` that only allows an exact match of `10.10.10.10` and `11.11.11.11`, enter the command:

```
config router access-list
   edit test_list
```

```
config rule
   edit 1
      set prefix 10.10.10.10 255.255.255.255
      set action allow
      set exact-match enable
   next
   edit 2
      set prefix 11.11.11.11 255.255.255.255
      set action allow
      set exact-match enable
   end
end
```

Another example is if you want to deny ranges of addresses in IPv6 that start with the IPv6 equivalents of 10.10.10.10 and 11.11.11.11, enter the command access-list6 as follows:

```
config router access-list6
   edit test_list_ip6
      config rule
         edit 1
            set prefix6 2002:A0A:A0A:0:0:0:0:0:/48
            set action deny
         next
         edit 2
            set prefix6 2002:B0B:B0B:0:0:0:0:0/48
            set action deny
         end
```

To use an access_list, you must call it from a routing protocol such as RIP. The following example uses the access_list from the earlier example called test_list to match routes coming in on the port1 interface. When there is a match, it will add 3 to the hop count metric for those routes to artificially decrease their priority. Enter the following command:

```
config router ospf
   config distribute-list
      edit 5
         set access-list test_list
         set protocol connected
      end
```

If you are setting a prefix of 128.0.0.0, use the format 128.0.0.0/1. The default route 0.0.0.0/0 can not be exactly matched with an access-list. A prefix-list must be used for this purpose.

How OSPF works

An OSPF installation consists of one or more areas. An OSPF area is typically divided into logical areas linked by Area Border Routers. A group of contiguous networks form an area. An Area Border Router (ABR) links one or more areas to the OSPF network backbone (area ID 0). See Dynamic Routing Overview on page 2371.

OSPF is an interior routing protocol. It includes a backbone AS, and possibly additional ASes. The DR and BDR are elected from potential routers with the highest priorities. The DR handles much of the administration to lower the network traffic required. New routers are discovered through hello packets sent from the DR using the multicast address of 224.0.0.5. If the DR goes offline at any time, the BDR has a complete table of routes that is uses when it takes over as the DR router.

OSPF does not use UDP or TCP, but is encapsulated directly in IP datagrams as protocol 89. This is in contrast to RIP, or BGP. OSPF handles its own error detection and correction functions.

The OSPF protocol, when running on IPv4, can operate securely between routers, optionally using a variety of authentication methods to allow only trusted routers to participate in routing. OSPFv3, running on IPv6, no longer supports protocol-internal authentication. Instead, it relies on IPv6 protocol security (IPsec).

Other important parts of how OSPF works includes:

- OSPF router discovery
- How OSPF works on FortiGate units
- External routes
- Link-state Database (LSDB) and route updates
- OSPF packets

OSPF router discovery

OSPF-enabled routers generate Link-State Advertisements (LSA) and send them to their neighbors whenever the status of a neighbor changes or a new neighbor comes online. As long as the OSPF network is stable, LSAs between OSPF neighbors do not occur. An LSA identifies the interfaces of all OSPF-enabled routers in an area, and provides information that enables OSPF-enabled routers to select the shortest path to a destination. All LSA exchanges between OSPF-enabled routers are authenticated.

When a network of OSPF routers comes online, the follow steps occur.

1. When OSPF routers come online, they send out Hello packets to find other OSPF routers on their network segment.
2. When they discover other routers on their network segment, generally they become adjacent. Adjacent routers can exchange routing updates. See Adjacency on page 465.
3. A DR and BDR are elected from the available routers using priority settings, and router ID. See Designated router (DR) and backup router (BDR) on page 465, and OSPF Background and concepts on page 463.
4. Link state updates are sent between adjacent routers to map the topology of the OSPF area.
5. Once complete, the DR floods the network with the updates to ensure all OSPF routers in the area have the same OSPF route database. After the initial update, there are very few required updates if the network is stable.

How OSPF works on FortiGate units

When a FortiGate unit interface is connected to an OSPF area, that unit can participate in OSPF communications. FortiGate units use the OSPF Hello protocol to acquire neighbors in an area. A neighbor is any router that is directly connected to the same area as the FortiGate unit, and ideally is adjacent with a state of Full. After initial contact, the FortiGate unit exchanges Hello packets with its OSPF neighbors regularly to confirm that the neighbors can be reached.

The number of routes that a FortiGate unit can learn through OSPF depends on the network topology. A single unit can support tens of thousands of routes if the OSPF network is configured properly.

External routes

OSPF is an internal routing protocol. OSPF external routes are routes where the destination using a routing protocol other than OSPF. OSPF handles external routes by adjusting the cost of the route to include the cost of the other routing protocol. There are two methods of calculating this cost, used for OSPF E1 and OSPF E2.

OSPF external1 (E1)

In OSPF E1 the destination is outside of the OSPF domain. This requires a different metric to be used beyond the normal OSPF metrics. The new metric of a redistributed route is calculated by adding the external cost and the OSPF cost together.

OSPF external2 (E2)

OSPF E2 is the default external type when routes are redistributed outside of OSPF. With OSPF E2, the metric of the redistributed route is equivalent to the external cost only, expressed as an OSPF cost. Dropping the OSPF portion can be useful in a number of situations, on border routers that have no OSPF portion for example or where the OSPF routing cost is negligible compared to the external routing cost.

Comparing E1 and E2

The best way to understand OSPF E1 and E2 routes is to check routing tables on OSPF routers. If you look at the routes on an OSPF border router, the redistributed routes will have an associated cost that represents only the external route, as there is no OSPF cost to the route due to it already being on the edge of the OSPF domain. However, if you look at that same route on a different OSPF router inside the OSPF routing domain, it will have a higher associated cost - essentially the external cost plus the cost over the OSPF domain to that border router. The border router uses OSPF E2, where the internal OSPF router uses OSPF E1 for the same route.

Viewing external routes

When you are trying to determine the costs for routes in your network to predict how traffic will be routed, you need to see the external OSPF routes and their associated costs. On your FortiGate unit, you find this information through your CLI.

To view external routes - CLI

You can view the whole routing table using `get router info routing-table all` to see all the routes including the OSPF external routes, or for a shorter list you can use the command `get router info routing-table ospf`. The letter at the left will be either E1 or E2 for external OSPF routes. The output of will look similar to the following, depending on what routes are in your routing table.

```
FGT620B# get router info routing-table all
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
O - OSPF, IA - OSPF inter area
N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
E1 - OSPF external type 1, E2 - OSPF external type 2
i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
* - candidate default

O*E2   0.0.0.0/0 [110/10] via 10.1.1.3, tunnel_wan2, 00:02:11
O      10.0.0.1/32 [110/300] via 10.1.1.3, tunnel_wan2, 00:02:11
S      0.0.0.0/0 [10/0] via 192.168.183.254, port2
S      1.0.0.0/8 [10/0] via 192.168.183.254, port2
```

Link-state Database (LSDB) and route updates

OSPF is based on links. The links between adjacent neighbor routers allow updates to be passed along the network. Network links allow the DR to flood the area with Link-state database (LSDB) updates. External links

allow the OSPF area to connect to destinations outside the OSPF autonomous system. Information about these links is passed throughout the OSPF network as link-state updates.

The LSDB contains the information that defines the complete OSPF area, but the LSDB is not the routing table. It contains the information from all the link-state updates passed along the network. When there are no more changes required, and the network is stable then the LSDB on each router in the network will be the same. The DR will flood the LSDB to the area to ensure each router has the same LSDB.

To calculate the best route (shortest path) to a destination, the FortiGate unit applies the Shortest Path First (SPF) algorithm, based on Dijkstra's algorithm, to the accumulated link-state information. OSPF uses relative path cost metric for choosing the best route. The path cost can be any metric, but is typically the bandwidth of the path, how fast traffic will get from one point to another.

The path cost, similar to "distance" for RIP, imposes a penalty on the outgoing direction of a FortiGate unit interface. The path cost of a route is calculated by adding together all of the costs associated with the outgoing interfaces along the path to the destination. The lowest overall path cost indicates the best route, and generally the fastest route. Some brands of OSPF routers, such as Cisco, implement cost as a direct result of bandwidth between the routers. Generally this is a good cost metric because larger bandwidth means more traffic can travel without slowing down. To achieve this type of cost metric on FortiGate units, you need to set the cost for each interface manually in the CLI.

The inter-area routes may not be calculated when a Cisco type ABR has no fully adjacent neighbor in the backbone area. In this situation, the router considers summary-LSAs from all Actively summary-LSAs from all Actively Attached areas (RFC 3509).

The FortiGate unit dynamically updates its routing table based on the results of the SPF calculation to ensure that an OSPF packet will be routed using the shortest path to its destination. Depending on the network topology, the entries in the FortiGate unit routing table may include:

- The addresses of networks in the local OSPF area (to which packets are sent directly)
- Routes to OSPF area border routers (to which packets destined for another area are sent)
- If the network contains OSPF areas and non-OSPF domains, routes to area boundary routers, which reside on the OSPF network backbone and are configured to forward packets to destinations outside the OSPF AS.

OSPF Route updates

Once the OSPF domain is established, there should be few updates required on a stable network. When updates occur and a decision is required concerning a new route, this is the general procedure.

Our router gets a new route, and needs to decide if it should go in the routing table.

The router has an up to date LSDB of the entire area, containing information about each router, the next hop to it, and most importantly the cost to get there.

Our router, turns the LSDB into a shortest path first (SPF) tree using Dijkstra's algorithm. It doesn't matter if there is more than one path to a router on the network, the SPF tree only cares about the shortest path to that router.

Once the SPF tree has been created, and shows the shortest paths to all the OSPF routers on the network, the work is done. If the new route is the best route, it will be part of that tree. If it is not the shortest route, it will not be included in the LSDB.

If there has been a change from the initial LSDB to the new SPF tree, a link state update will be sent out to let the other routers know about the change so they can update their LSDBs as well. This is vital since all routers on the OSPF area must have the same LSDB.

If there was no change between the LSDB and the SPF tree, no action is taken.

OSPF packets

Every OSPF packet starts with a standard 24-byte header, and another 24 bytes of information or more. The header contains all the information necessary to determine whether the packet should be accepted for further processing.

OSPF packet

1-byte Version field	1-byte Type field	2-byte Packet length	3-byte Router ID
4-byte Area ID	2-byte Checksum	2-byte Auth Type	8-byte Authentication
4-byte Network Mask	2-byte Hello interval	1-byte Options field	1-byte Router Priority
4-byte Dead Router interval	4-byte DR field	4-byte BDR field	4-byte Neighbor ID

The following descriptions summarize the OSPF packet header fields.

Version field — The OSPF version number. This specification documents version 2 of the protocol.

Type field — There are 5 OSPF packet types. From one to five, respectively, they are Hello, Database Description, Link State Request, Link State Update, and Link State Acknowledgment.

Packet length — The length of the OSPF protocol packet in bytes. This length includes the standard OSPF 24-byte header, so all OSPF packets are at 24-bytes long.

Router ID — The Router ID of the packet's source.

Area ID — A 32-bit number identifying the area that this packet belongs to. All OSPF packets are associated with a single area. Most travel a single hop only. Packets travelling over a virtual link are labelled with the backbone Area ID of 0.0.0.0.

Checksum — The standard IP checksum of the entire contents of the packet, starting with the OSPF packet header but excluding the 64-bit authentication field. This checksum is calculated as the 16-bit one's complement of the one's complement sum of all the 16-bit words in the packet, excepting the authentication field. If the packet's length is not an integral number of 16-bit words, the packet is padded with a byte of zero before checksumming. The checksum is considered to be part of the packet authentication procedure; for some authentication types the checksum calculation is omitted.

Auth Type — Identifies the authentication procedure to be used for the packet. Authentication types include Null authentication (0), Simple password (1), Cryptographic authentication (2), and all others are reserved for future use.

Authentication — A 64-bit field for use by the authentication scheme. When AuType indicates no authentication is being used, the Authentication fields is not checked and can be any value. When AuType is set to 2 (Cryptographic authentication), the 64-bit authentication field is split into the following four fields: Zero field, Key ID field, Authentication data length field, and Cryptographic sequence field.

The Key ID field indicates the key and algorithm used to create the message digest appended to the packet. The authentication data length field indicates how many bytes long the message digest is, and the cryptographic sequence number is at non-decreasing number that is set when the packet is received and authenticated to prevent replay attacks.

Network Mask — The subnet where this packet is valid.

Hello interval — The period of time between sending out Hello packets. See Hello and dead intervals on page 469.

Options field — The OSPF protocol defines several optional capabilities. A router indicates the optional capabilities that it supports in its OSPF Hello packets, Database Description packets and in its LSAs. This enables routers supporting a mix of optional capabilities to coexist in a single Autonomous System.

Router priority — The priority between 0 and 255 that determines which routers become the DR and BDR. See Designated router (DR) and backup router (BDR) on page 465.

Dead router interval — The period of time when there is no response from a router before it is declared dead. See Hello and dead intervals on page 469.

DR and BDR fields — The DR and BDR fields each list the router that fills that role on this network, generally the routers with the highest priorities. See Designated router (DR) and backup router (BDR) on page 465.

Neighbor ID — The ID number of a neighboring router. This ID is used to discover new routers and respond to them.

Troubleshooting OSPF

As with other dynamic routing protocols, OSPF has some issues that may need troubleshooting from time to time. For basic troubleshooting, see the FortiOS Handbook Troubleshooting chapter.

The more common issues include:

- Clearing OSPF routes from the routing table
- Checking the state of OSPF neighbors
- Passive interface problems
- Timer problems
- Bi-directional Forwarding Detection (BFD)
- Authentication issues
- DR and BDR election issues

Clearing OSPF routes from the routing table

If you think the wrong route has been added to your routing table and you want to check it out, you first have to remove that route from your table before seeing if it is added back in or not. You can clear all or some OSPF neighbor connections (sessions) using the `execute router clear ospf` command. The exec router clear command is much more limiting for OSPF than it is for BGP. See Border Gateway Protocol (BGP) on page 2465.

For example, if you have routes in the OSPF routing table and you want to clear the specific route to IP address 10.10.10.1, you will have to clear all the OSPF entries. Enter the command:

```
execute router clear ospf process
```

Checking the state of OSPF neighbors

In OSPF each router sends out link state advertisements to find other routers on its network segment, and to create adjacencies with some of those routers. This is important because routing updates are only passed between adjacent routers. If two routers you believe to be adjacent are not, that can be the source of routing failures.

To identify this problem, you need to check the state of the OSPF neighbors of your FortiGate unit. Use the CLI command `get router info ospf neighbor all` to see all the neighbors for your FortiGate unit. You will see output in the form of:

```
FGT1 # get router info ospf neighbor
OSPF process 0:
Neighbor ID  Pri  State    Dead Time Address Interface
10.0.0.2     1    Full/ -  00:00:39 10.1.1.2 tunnel_wan1
10.0.0.2     1    Full/ -  00:00:34 10.1.1.4 tunnel_wan2
```

The important information here is the `State` column. Any neighbors that are not adjacent to your FortiGate unit will be reported in this column as something other than `Full`. If the state is `Down`, that router is offline.

Passive interface problems

A passive OSPF interface doesn't send out any updates. This means it can't be a DR, BDR, or an area border router among other things. It will depend on other neighbor routers to update its link-state table.

Passive interfaces can cause problems when they aren't receiving the routing updates you expect from their neighbors. This will result in the passive OSPF FortiGate unit interface having an incomplete or out-of-date link-state database, and it will not be able to properly route its traffic. It is possible that the passive interface is causing a hole in the network where no routers are passing updates to each other, however this is a rare situation.

If a passive interface is causing problems, there are simple methods to determine it is the cause. The easiest method is to make it an active interface, and if the issues disappear, then that was the cause. Another method is to examine the OSPF routing table and related information to see if it is incomplete compared to other neighbor routers. If this is the case, you can clear the routing table, reset the device and allow it to repopulate the table.

If you cannot make the interface active for some reason, you will have to change your network to fix the "hole" by adding more routers, or changing the relationship between the passive router's neighbors to provide better coverage.

Timer problems

A timer mismatch is when two routers have different values set for the same timer. For example if one router declares a router dead after 45 seconds and another waits for 4 minutes that difference in time will result in those two routers being out of synch for that period of time—one will still see that offline router as being online.

The easiest method to check the timers is to check the configuration on each router. Another method is to sniff some packets, and read the timer values in the packets themselves from different routers. Each packet contains the hello interval, and dead interval periods, so you can compare them easily enough.

Bi-directional Forwarding Detection (BFD)

Bi-directional Forwarding Detection (BFD) is a protocol used to quickly locate hardware failures in the network. Routers running BFD communicate with each other, and if a timer runs out on a connection then that router is declared down. BFD then communicates this information to the routing protocol and the routing information is updated.

Authentication issues

OSPF has a number of authentication methods you can choose from. You may encounter problems with routers not authenticating as you expect. This will likely appear simply as one or more routers that have a blind spot in their routing - they won't acknowledge a router. This can be a problem if that router connects areas to the backbone as it will appear to be offline and unusable.

To confirm this is the issue, the easiest method is to turn off authentication on the neighboring routers. With no authentication between any routers, everything should flow normally.

Another method to confirm that authentication is the problem is to sniff packets, and look at their contents. The authentication type and password are right in the packets which makes it easy to confirm they are what you expect during real time. Its possible one or more routers is not configured as you expect and may be using the wrong authentication. This method is especially useful if there are a group of routers with these problems—it may only be one router causing the problem that is seen in multiple routers.

Once you have confirmed the problem is authentication related, you can decide how to handle it. You can turn off authentication and take your time to determine how to get your preferred authentication type back online. You can try another type of authentication, such as text instead of md5, which may have more success and still provide some level of protection. The important part is that once you confirm the problem, you can decide how to fix it properly.

DR and BDR election issues

You can force a particular router to become the DR and BDR by setting their priorities higher than any other OSPF routers in the area. This is a good idea when those routers have more resources to handle the traffic and extra work of the DR and BDR roles, since not all routers may be able to handle all that traffic.

However, if you set all the other routers to not have a chance at being elected, a priority of zero, you can run into problems if the DR and BDR go offline. The good part is that you will have some warning generally as the DR goes offline and the BDR is promoted to the DR position. But if the network segment with both the DR and BDR goes down, your network will have no way to send hello packets, send updates, or the other tasks the DR performs.

The solution to this is to always allow routers to have a chance at being promoted, even if you set their priority to one. In that case they would be the last choice, but if there are no other candidates you want that router to become the DR. Most networks would have already alerted you to the equipment problems, so this would be a temporary measure to keep the network traffic moving until you can find and fix the problem to get the real DR back online.

Basic OSPF example

This example sets up an OSPF network at a small office. There are 3 routers, all running OSPF v2. The border router connects to a BGP network.

All three routers in this example are FortiGate units. Router1 will be the designated router (DR) and router2 will be the backup DR (BDR) due to their priorities. Router3 will not be considered for either the DR or BDR elections. Instead, Router3 is the area border router (ASBR) routing all traffic to the ISP's BGP router on its way to the Internet.

Router2 has a modem connected that provides dialup access to the Internet as well, at a reduced bandwidth. This is a PPPoE connection to a DSL modem. This provides an alternate route to the Internet if the other route goes down. The DSL connection is slow, and is charged by the amount of traffic. For these reasons OSPF will highly favor Router3's Internet access.

The DSL connection connects to an OSPF network with the ISP, so no redistribution of routes is required. The ISP network does have to be added to that router's configuration however.

This section includes the following topics:

- Network layout and assumptions
- Configuring the FortiGate units
- Configuring OSPF on the FortiGate units
- Configuring other networking devices
- Testing network configuration

Network layout and assumptions

There are three FortiGate units acting as OSPF v2 routers on the network—Router1, Router2, and Router3. Router1 will be the designated router (DR), and Router 2 the BDR. Router3 is the area border router (ASBR) that connects to the external ISP router running BGP. Router2 has a PPPoE DSL connection that can access the Internet.

The Head Office network is connected to Router1 and Router2 on the 10.11.101.0 subnet.

Router1 and Router3 are connected over the 10.11.103.0 subnet.

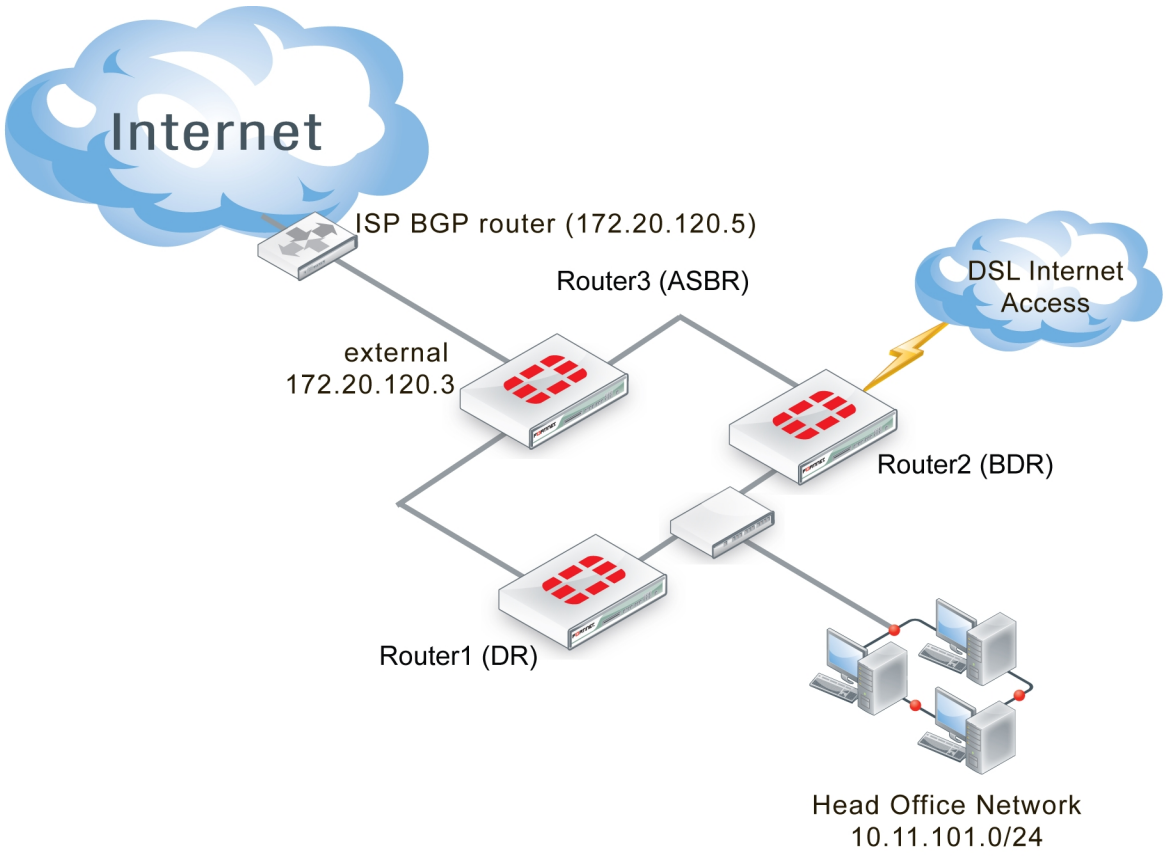
Router2 and Router3 are connected over the 10.11.102.0 subnet.

The following table lists the router, interface, address, and role it is assigned.

Routers, interfaces, and IP addresses for basic OSPF example network

Router name	Interface	IP address	Interface is connected to:
Router1 (DR)	Internal (port1)	10.11.101.1	Head office network, and Router2
	External (port2)	10.11.102.1	Router3
Router2 (BDR)	Internal (port1)	10.11.101.2	Head office network, and Router1
	External (port2)	10.11.103.2	Router3
	DSL (port3)	10.12.101.2	PPPoE DSL access
	Internal1 (port1)	10.11.102.3	Router1
Router3 (ASBR)	Internal2 (port2)	10.11.103.3	Router2
	External (port3)	172.20.120.3	ISP's BGP network

Basic OSPF network topology



Note that other subnets can be added to the internal interfaces without changing the configuration.

Assumptions

- The FortiGate units used in this example have interfaces named port1, port2, and port3.
- All FortiGate units in this example have factory default configuration with FortiOS 4.0 MR2 firmware installed, and are in NAT/Route operation mode.
- Basic firewalls are in place to allow unfiltered traffic between all connected interfaces in both directions.
- This OSPF network is not connected to any other OSPF networks.
- Both Internet connections are always available.
- The modem connection is very slow and expensive.
- Other devices may be on the network, but do not affect this basic configuration.
- Router3 is responsible for redistributing all routes into and out of the OSPF AS.

Configuring the FortiGate units

Each FortiGate unit needs the interfaces, and basic system information such as hostname configured.

This section includes:

- Configuring Router1
- Configuring Router2

- Configuring Router3

Configuring Router1

Router1 has two interfaces connected to the network—internal (port1) and external (port2). Its host name must be changed to Router1.

To configure Router1 interfaces - web-based manager

1. Go to **Dashboard > System Information**.
2. Beside the host name, select **Change**.
3. Enter a hostname of `Router1`, and select **OK**.
4. Go to **Network > Interfaces**, edit port1, set the following information, and select **OK**.

Alias	internal
IP/Network Mask	10.11.101.1/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Head office and Router2
Administrative Status	Up

5. Edit port2, set the following information, and select **OK**.

Alias	External
IP/Network Mask	10.11.102.1/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Router3
Administrative Status	Up

Configuring Router2

Router2 configuration is the same as Router1, except Router2 also has the DSL interface to configure.

The DSL interface is configured with a username of “user1” and a password of “ospf_example”. The default gateway will be retrieved from the ISP, and the defaults will be used for the rest of the PPPoE settings.

To configure Router2 interfaces - web-based manager

1. Go to **Dashboard > System Information**.
2. Beside the host name, select **Change**.
3. Enter a hostname of `Router2`, and select **OK**.
4. Go to **Network > Interfaces**, edit port1, set the following information, and select **OK**.

Alias	internal

IP/Network Mask	10.11.101.2/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Head office and Router1
Administrative Status	Up

5. Edit port2, set the following information, and select **OK**.

Alias	External
IP/Network Mask	10.11.103.2/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Router3
Administrative Status	Up

6. Edit DSL (port3), set the following information, and select **OK**.

Alias	DSL
Addressing Mode	PPPoE
Username	user1
Password	ospf_example
Unnumbered IP	10.12.101.2/255.255.255.0
Retrieve default gateway from server	Enable
Administrative Access	HTTPS SSH PING
Description	DSL
Administrative Status	Up

Configuring Router3

Router3 is similar to Router1 and Router2 configurations. The main difference is the External (port3) interface connected to the ISP BGP network which has no administration access enabled for security reasons.

To configure Router3 interfaces - web-based manager

1. Go to **Dashboard > System Information**.
2. Next to hostname, select **Change**.
3. Enter a hostname of `Router3`, and select **OK**.
4. Go to **Network > Interfaces, e**dit port1, set the following information, and select **OK**.

Alias	internal
IP/Network Mask	10.11.102.3/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Router1
Administrative Status	Up

5. Edit port2, set the following information, and select **OK**.

Alias	Internal2
IP/Network Mask	10.11.103.3/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Router2
Administrative Status	Up

6. Edit port3, set the following information, and select **OK**.

Alias	External
IP/Network Mask	172.20.120.3/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	ISP BGP
Administrative Status	Up

Configuring OSPF on the FortiGate units

With the interfaces configured, now the FortiGate units can be configured for OSPF on those interfaces. All routers are part of the backbone 0.0.0.0 area, so there is no inter-area communications needed.

For a simple configuration there will be no authentication, no graceful restart or other advanced features, and timers will be left at their defaults. Also the costs for all interfaces will be left at 10, except for the modem and ISP interfaces where cost will be used to load balance traffic. Nearly all advanced features of OSPF are only available from the CLI.

The network that is defined covers all the subnets used in this example - 10.11.101.0, 10.11.102.0, and 10.11.103.0. All routes for these subnets will be advertised. If there are other interfaces on the FortiGate units that you do not want included in the OSPF routes, ensure those interfaces use a different subnet outside of the 10.11.0.0 network. If you want all interfaces to be advertised you can use an OSPF network of 0.0.0.0 .

Each router will configure:

- Router ID
- Area
- Network

- Two or three interfaces depending on the router
- Priority for DR (Router1) and BDR (Router2)
- Redistribute for ASBR (Router3)

This section includes:

- Configuring OSPF on Router1
- Configuring OSPF on Router2
- Configuring OSPF on Router3

Configuring OSPF on Router1

Router1 has a very high priority to ensure it becomes the DR for this area. Also Router1 has the lowest IP address to help ensure it will win in case there is a tie at some point. Otherwise it is a standard OSPF configuration. Setting the priority can only be done in the CLI, and it is for a specific OSPF interface.

To configure OSPF on Router1 - web-based manager

1. Go to **Network > OSPF**.
2. Set **Router ID** to `10.11.101.1` and select **Apply**.
3. In **Areas**, select **Create New,** set the following information, and select **OK**.

Area	0.0.0.0
Type	Regular
Authentication	none

4. In **Networks**, select **Create New**, set the following information, and select **OK**.

IP/Netmask	10.11.0.0/255.255.0.0
Area	0.0.0.0

5. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

Name		Router1-Internal-DR
Interface		port1 (Internal)
IP		0.0.0.0
Authentication		none
Timers (seconds)		
	Hello Interval	10
	Dead Interval	40

6. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

Name		Router1-External
Interface		port2 (External)
IP		0.0.0.0
Authentication		none
Timers (seconds)		
	Hello Interval	10
	Dead Interval	40

7. Using the CLI, enter the following commands to set the priority for the Router1-Internal OSPF interface to maximum, ensuring this interface becomes the DR.

```
config router ospf
   config ospf-interface
      edit Router1-Internal-DR
         set priority 255
      end
```

To configure OSPF on Router1 - CLI

```
config router ospf
   set router-id 10.11.101.1
   config area
      edit 0.0.0.0
      next
   end
   config network
      edit 1
         set prefix 10.11.0.0/255.255.255.0
      next
   end
   config ospf-interface
      edit "Router1-Internal"
         set interface "port1"
         set priority 255
      next
      edit "Router1-External"
         set interface "port2"
      next
   end
end
```

Configuring OSPF on Router2

Router2 has a high priority to ensure it becomes the BDR for this area, and configures the DSL interface slightly differently—assume this will be a slower connection resulting in the need for longer timers, and a higher cost for this route.

Otherwise it is a standard OSPF configuration.

To configure OSPF on Router2 - web-based manager

1. Go to **Network > OSPF**.
2. Set **Router ID** to `10.11.101.2` and select **Apply**.
3. In **Areas**, select **Create New**, set the following information, and select **OK**.

Area	0.0.0.0
Type	Regular
Authentication	none

4. In **Networks**, select **Create New**, set the following information, and select **OK**.

IP/Netmask	10.11.0.0/255.255.0.0
Area	0.0.0.0

5. In **Interfaces**, select **Create New,** set the following information, and select **OK**.

Name	Router2-Internal
Interface	port1 (Internal)
IP	0.0.0.0
Authentication	none
Timers (seconds)	
Hello Interval	10
Dead Interval	40

6. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

Name	Router2-External
Interface	port2 (External)
IP	0.0.0.0
Authentication	none
Timers (seconds)	
Hello Interval	10
Dead Interval	40

7. In **Interfaces**, select **Create New,** set the following information, and select **OK**.

Name		Router2-DSL
Interface		port3 (DSL)
IP		0.0.0.0
Authentication		none
Cost		50
Timers (seconds)		
	Hello Interval	20
	Dead Interval	80

8. Using the CLI, enter the following commands to set the priority for the Router2-Internal OSPF interface to ensure this interface will become the BDR:

```
config router ospf
   config ospf-interface
      edit Router2-Internal
         set priority 250
      next
   end
```

To configure OSPF on Router2 - CLI

```
config router ospf
   set router-id 10.11.101.2
   config area
      edit 0.0.0.0
      next
   end
   config network
      edit 1
         set prefix 10.11.0.0/255.255.0.0
      next
   end
   config ospf-interface
      edit "Router2-Internal"
         set interface "port1"
         set priority 255
      next
      edit "Router2-External"
         set interface "port2"
      next
      edit "Router2-DSL"
         set interface "port3"
         set cost 50
      next
   end
end
```

Configuring OSPF on Router3

Router3 is more complex than the other two routers. The interfaces are straightforward, but this router has to import and export routes between OSPF and BGP. That requirement makes Router3 a border router or ASBR. Also Router3 needs a lower cost on its route to encourage all traffic to the Internet to route through it.

In the advanced OSPF options, Redistribute is enabled for Router3. It allows different types of routes, learned outside of OSPF, to be used in OSPF. Different metrics are assigned to these other types of routes to make them more or less preferred to regular OSPF routes.

To configure OSPF on Router3 - web-based manager

1. Go to **Network > OSPF**.
2. Set **Router ID** to `10.11.101.2` and select **Apply**.
3. Expand **Advanced Options**.
4. In **Redistribute**, set the following information, and select **OK**.

Route type	Redistribute	Metric
Connected	Enable	15
Static	Enable	15
RIP	Disable	n/a
BGP	Enable	5

5. In **Areas**, select **Create New**, set the following information, and select **OK**.

Area	0.0.0.0
Type	Regular
Authentication	none

6. In **Networks**, select **Create New**, set the following information, and select **OK**.

IP/Netmask	10.11.0.0/255.255.0.0
Area	0.0.0.0

7. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

Name	Router3-Internal
Interface	port1 (Internal)
IP	0.0.0.0
Authentication	none

Timers (seconds)		
	Hello Interval	10
	Dead Interval	40

8. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

Name	Router3-Internal2
Interface	port2 (Internal2)
IP	0.0.0.0
Authentication	none
Timers (seconds)	
Hello Interval	10
Dead Interval	40

9. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

Name	Router3-ISP-BGP
Interface	port3 (ISP-BGP)
IP	0.0.0.0
Authentication	none
Cost	2
Timers (seconds)	
Hello Interval	20
Dead Interval	80

10. Using the CLI, enter the following commands to set the priority for the Router3-Internal OSPF interface to ensure this interface will become the BDR.

```
config router ospf
   config ospf-interface
   edit Router3-Internal
      set priority 250
   next
end
```

To configure OSPF on Router3 - CLI

```
config router ospf
   set router-id 10.11.102.3
   config area
      edit 0.0.0.0
```

```
      next
    end
    config network
      edit 1
        set prefix 10.11.0.0/255.255.255.0
      next
      edit 2
        set prefix 172.20.120.0/255.255.255.0
      next
    end
    config ospf-interface
      edit "Router3-Internal"
        set interface "port1"
        set priority 255
      next
      edit "Router3-External"
        set interface "port2"
      next
      edit "Router3-ISP-BGP"
        set interface "port3"
        set cost 2
      next
    end
  end
```

Configuring other networking devices

The other networking devices required in this configuration are on the two ISP networks, the BGP network for the main Internet connection, and the DSL backup connection.

In both cases, the ISPs need to be notified of the OSPF network settings including router IP addresses, timer settings, and so on. The ISP will use this information to configure its routers that connect to this OSPF network.

Testing network configuration

Testing the network configuration involves two parts: testing the network connectivity, and testing the OSPF routing.

To test the network connectivity use ping, traceroute, and other network tools.

To test the OSPF routing in this example, refer to the troubleshooting outlined in Basic OSPF example on page 477.

Advanced inter-area OSPF example

This example sets up an OSPF network at a large office. There are three areas, each with two routers. Typically OSPF areas would not be this small, and if they were the areas would be combined into one bigger area. However, the stub area services the accounting department which is very sensitive about their network and do not want any of their network information broadcast through the rest of the company. The backbone area contains the bulk of the company network devices. The regular area was established for various reasons such as hosting the company servers on a separate area with extra security.

One area is a small stub area that has no independent Internet connection, and only one connection to the backbone area. That connection between the stub area and the backbone area is only through a default route. No routes outside the stub area are advertised into that area. Another area is the backbone, which is connected to

the other two areas. The third area has the Internet connection, and all traffic to and from the Internet must use that area's connection. If that traffic comes from the stub area, then that traffic is treating the backbone like a transit area that only uses it to get to another area.

In the stub area, a subnet of computers is running the RIP routing protocol and those routes must be redistributed into the OSPF areas.

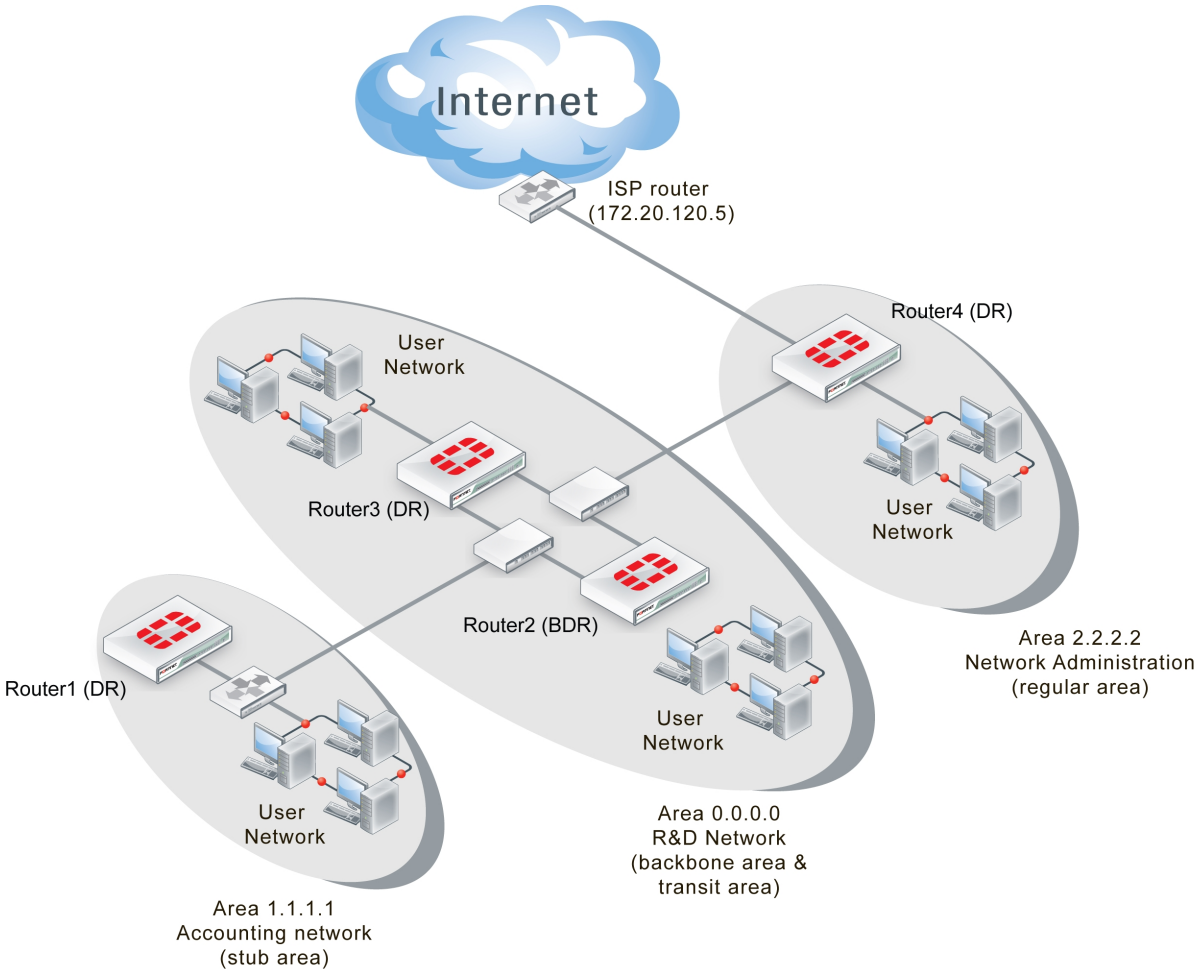
This section includes the following topics:

- Network layout and assumptions
- Configuring the FortiGate units
- Configuring OSPF on the FortiGate units
- Configuring other networking devices
- Testing network configuration

Network layout and assumptions

There are four FortiGate units in this network topology acting as OSPF routers:

Advanced inter-area OSPF network topology



Area 1.1.1.1 is a stub area with one FortiGate unit OSPF router called Router1 (DR). Its only access outside of that area is a default route to the backbone area, which is how it accesses the Internet. Traffic must go from the stub area, through the backbone, to the third area to reach the Internet. The backbone area in this configuration is called a transit area. Also in area 1.1.1.1 there is a RIP router that will be providing routes to the OSPF area through redistribution.

Area 0.0.0.0 is the backbone area, and has two FortiGate unit routers named Router2 (BDR) and Router3 (DR).

Area 2.2.2.2 is a regular area that has an Internet connection accessed by both the other two OSPF areas. There is only one FortiGate unit router in this area called Router4 (DR). This area is more secure and requires MD5 authentication by routers.

All areas have user networks connected, but they are not important for configuring the network layout for this example.

Internal interfaces are connected to internal user networks only. External1 interfaces are connected to the 10.11.110.0 network, joining Area 1.1.1.1 and Area 0.0.0.0.

External2 interfaces are connected to the 10.11.111.0 network, joining Area 0.0.0.0 and Area 2.2.2.2. The ISP interface is called ISP.

Routers, areas, interfaces, IP addresses for advanced OSPF network

Router name	Area number and type	Interface	IP address
Router1 (DR)	1.1.1.1 - stub area (Accounting)	port1 (internal)	10.11.101.1
		port2 (external1)	10.11.110.1
Router2 (BDR)	0.0.0.0 - backbone area (R&D Network)	port1 (internal)	10.11.102.2
		port2 (external1)	10.11.110.2
		port3 (external2)	10.11.111.2
Router3 (DR)	0.0.0.0 - backbone area (R&D Network)	port1 (internal)	10.11.103.3
		port2 (external1)	10.11.110.3
		port3 (external2)	10.11.111.3
Router4 (DR)	2.2.2.2 - regular area (Network Admin)	port1 (internal)	10.11.104.4
		port2 (external2)	10.11.111.4
		port3 (ISP)	172.20.120.4

Note that other subnets can be added to the internal interfaces without changing the configuration.

Assumptions

- The FortiGate units used in this example have interfaces named port1, port2, and port3.
- All FortiGate units in this example have factory default configuration with FortiOS 4.0 MR2 firmware installed, and are in NAT/Route operation mode.
- During configuration, if settings are not directly referred to they will be left at default settings.
- Basic firewalls are in place to allow unfiltered traffic between all connected interfaces in both directions.
- This OSPF network is not connected to any other OSPF areas outside of this example.
- The Internet connection is always available.
- Other devices may be on the network, but do not affect this configuration.

Configuring the FortiGate units

This section configures the basic settings on the FortiGate units to be OSPF routers. These configurations include multiple interface settings, and hostname.

There are four FortiGate units in this example. The two units in the backbone area can be configured exactly the same except for IP addresses, so only router3 (the DR) configuration will be given with notes indicating router2 (the BDR) IP addresses.

Configuring the FortiGate units includes:

- Configuring Router1
- Configuring Router2
- Configuring Router3
- Configuring Router4

Configuring Router1

Router1 is part of the Accounting network stub area (1.1.1.1).

To configure Router1 interfaces - web-based manager

1. Go to **Dashboard > System Information**.
2. Next to hostname, select **Change**.
3. Enter a hostname of `Router1`, and select **OK**.
4. Go to **Network > Interfaces,** edit port1, set the following information, and select **OK**.

Alias	internal
IP/Network Mask	10.11.101.1/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Accounting network
Administrative Status	Up

5. Edit port2, set the following information, and select **OK**.

Alias	External1
IP/Network Mask	10.11.110.1/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Backbone network and Internet
Administrative Status	Up

Configuring Router2

Router2 is part of the R&D network backbone area (0.0.0.0). Router2 and Router3 are in this area. They provide a redundant connection between area 1.1.1.1 and area 2.2.2.2.

Router2 has three interfaces configured; one to the internal network, and two to Router3 for redundancy.

To configure Router2 interfaces - web-based manager

1. Go to **Dashboard > System Information**.
2. Next to hostname, select **Change**.
3. Enter a hostname of `Router2`, and select **OK**.
4. Go to **Network > Interfaces**, edit port1 (internal), set the following information, and select **OK**.

Alias	internal
IP/Network Mask	10.11.102.2/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Internal RnD network
Administrative Status	Up

5. Edit port2 (external1), set the following information, and select **OK**.

Alias	external1
IP/Network Mask	10.11.110.2/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Router3 first connection
Administrative Status	Up

6. Edit port3 (external2), set the following information, and select **OK**.

Alias	external2
IP/Network Mask	10.11.111.2/255.255.255.0

Administrative Access	HTTPS SSH PING
Description	Router3 second connection
Administrative Status	Up

Configuring Router3

Router3 is part of the R&D network backbone area (0.0.0.0). Router2 and Router3 are in this area. They provide a redundant connection between area 1.1.1.1 and area 2.2.2.2.

To configure Router3 interfaces - web-based manager

1. Go to **Dashboard > System Information**.
2. Next to hostname, select **Change**.
3. Enter a hostname of `Router3`, and select **OK**.
4. Go to **Network > Interfaces**, edit port1 (internal), set the following information, and select **OK**.

Alias	internal
IP/Network Mask	10.11.103.3/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Internal RnD network
Administrative Status	Up

5. Edit port2 (external1), set the following information, and select **OK**.

Alias	external1
IP/Network Mask	10.11.110.3/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Router2 first connection
Administrative Status	Up

6. Edit port3 (external2), set the following information, and select **OK**.

Alias	external2
IP/Network Mask	10.11.111.3/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Router2 second connection
Administrative Status	Up

Configuring Router4

Router4 is part of the Network Administration regular area (2.2.2.2). This area provides Internet access for both area 1.1.1.1 and the backbone area.

This section configures interfaces and hostname.

To configure Router4 interfaces - web-based manager

1. Go to **Dashboard > System Information**.
2. Next to hostname, select **Change**.
3. Enter a hostname of `Router4`, and select **OK**.
4. Go to **Network > Interfaces**.
5. Edit port1 (internal).
6. Set the following information, and select **OK**.

Alias	internal
IP/Network Mask	10.11.101.4/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Accounting network
Administrative Status	Up

7. Edit port2 (external2).
8. Set the following information, and select **OK**.

Alias	external2
IP/Network Mask	10.11.110.4/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Backbone and Accounting network
Administrative Status	Up

9. Edit port3 (ISP).
10. Set the following information, and select **OK**.

Alias	ISP
IP/Network Mask	172.20.120.4/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	ISP and Internet
Administrative Status	Up

Configuring OSPF on the FortiGate units

Three of the routers are designated routers (DR) and one is a backup DR (BDR). This is achieved through the lowest router ID numbers, or OSPF priority settings.

Also each area needs to be configured as each respective type of area - stub, backbone, or regular. This affects how routes are advertised into the area.

To configure OSPF on Router1 - web-based manager

1. Go to **Network > OSPF**.
2. Enter `10.11.101.1` for the **Router ID** and select **Apply**.
3. In **Areas**, select **Create New,** set the following information, and select **OK**.

Area	1.1.1.1
Type	Stub
Authentication	None

4. In **Networks**, select **Create New,** set the following information, and select **OK**.

IP/Netmask	10.11.101.0/255.255.255.0
Area	1.1.1.1

5. In **Interfaces**, select **Create New,** set the following information, and select **OK**.

Name	Accounting
Interface	port1 (internal)
IP	10.11.101.1
Authentication	None

6. In **Interfaces**, select **Create New,** set the following information, and select **OK**.

Name	Backbone1
Interface	port2 (external1)
IP	10.11.110.1
Authentication	None

To configure OSPF on Router2 - web-based manager

1. Go to **Network > OSPF**.
2. Enter `10.11.102.2` for the **Router ID** and select **Apply**.
3. In **Areas**, select **Create New,** set the following information, and select **OK**.

Area	0.0.0.0
Type	Regular
Authentication	None

4. In **Networks**, select **Create New,** set the following information, and select **OK**.

IP/Netmask	10.11.102.2/255.255.255.0
Area	0.0.0.0

5. In **Networks**, select **Create New,** set the following information, and select **OK**.

IP/Netmask	10.11.110.2/255.255.255.0
Area	0.0.0.0

6. In **Networks**, select **Create New,** set the following information, and select **OK**.

IP/Netmask	10.11.111.2/255.255.255.0
Area	0.0.0.0

7. In **Interfaces**, select **Create New,** set the following information, and select **OK**.

Name	RnD network
Interface	port1 (internal)
IP	10.11.102.2
Authentication	None

8. In **Interfaces**, select **Create New,** set the following information, and select **OK**.

Name	Backbone1
Interface	port2 (external1)
IP	10.11.110.2
Authentication	None

9. In **Interfaces**, select **Create New,** set the following information, and select **OK**.

Name	Backbone2
Interface	port3 (external2)

IP	10.11.111.2
Authentication	None

To configure OSPF on Router3 - web-based manager

1. Go to **Network > OSPF**.
2. Enter `10.11.103.3` for the **Router ID** and then select **Apply**.
3. In **Areas**, select **Create New, s**et the following information, and then select **OK**.

Area	0.0.0.0
Type	Regular
Authentication	None

4. In **Networks**, select **Create New,** set the following information, and select **OK**.

IP/Netmask	10.11.102.3/255.255.255.0
Area	0.0.0.0

5. In **Networks**, select **Create New,** set the following information, and select **OK**.

IP/Netmask	10.11.110.3/255.255.255.0
Area	0.0.0.0

6. In **Networks**, select **Create New,** set the following information, and select **OK**.

IP/Netmask	10.11.111.3/255.255.255.0
Area	0.0.0.0

7. In **Interfaces**, select **Create New,** set the following information, and select **OK**.

Name	RnD network
Interface	port1 (internal)
IP	10.11.103.3
Authentication	None

8. In **Interfaces**, select **Create New,** set the following information, and select **OK**.

Name	Backbone1
Interface	port2 (external1)

IP	10.11.110.3
Authentication	None

9. In **Interfaces**, select **Create New,** set the following information, and select **OK**.

Name	Backbone2
Interface	port3 (external2)
IP	10.11.111.3
Authentication	None

To configure OSPF on Router4 - web-based manager

1. Go to **Network > OSPF**.
2. Enter `10.11.104.4` for the **Router ID** and then select **Apply**.
3. In **Areas**, select **Create New**.
4. Set the following information, and select **OK**.

Area	2.2.2.2
Type	Regular
Authentication	None

5. In **Networks**, select **Create New,** set the following information, and select **OK**.

IP/Netmask	10.11.104.0/255.255.255.0
Area	0.0.0.0

6. In **Networks**, select **Create New**, set the following information, and select **OK**.

IP/Netmask	10.11.111.0/255.255.255.0
Area	0.0.0.0

7. In **Networks**, select **Create New**, set the following information, and select **OK**.

IP/Netmask	172.20.120.0/255.255.255.0
Area	0.0.0.0

8. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

Name	Network Admin network

Interface	port1 (internal)
IP	10.11.104.4
Authentication	None

9. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

Name	Backbone2
Interface	port2 (external2)
IP	10.11.111.4
Authentication	None

10. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

Name	ISP
Interface	port3 (ISP)
IP	172.20.120.4
Authentication	None

Configuring other networking devices

All network devices on this network are running OSPF routing. The user networks (Accounting, R&D, and Network Administration) are part of one of the three areas.

The ISP needs to be notified of your network configuration for area 2.2.2.2. Your ISP will not advertise your areas externally as they are intended as internal areas. External areas have assigned unique numbers. The area numbers used in this example are similar to the 10.0.0.0 and 192.168.0.0 subnets used in internal networking.

Testing network configuration

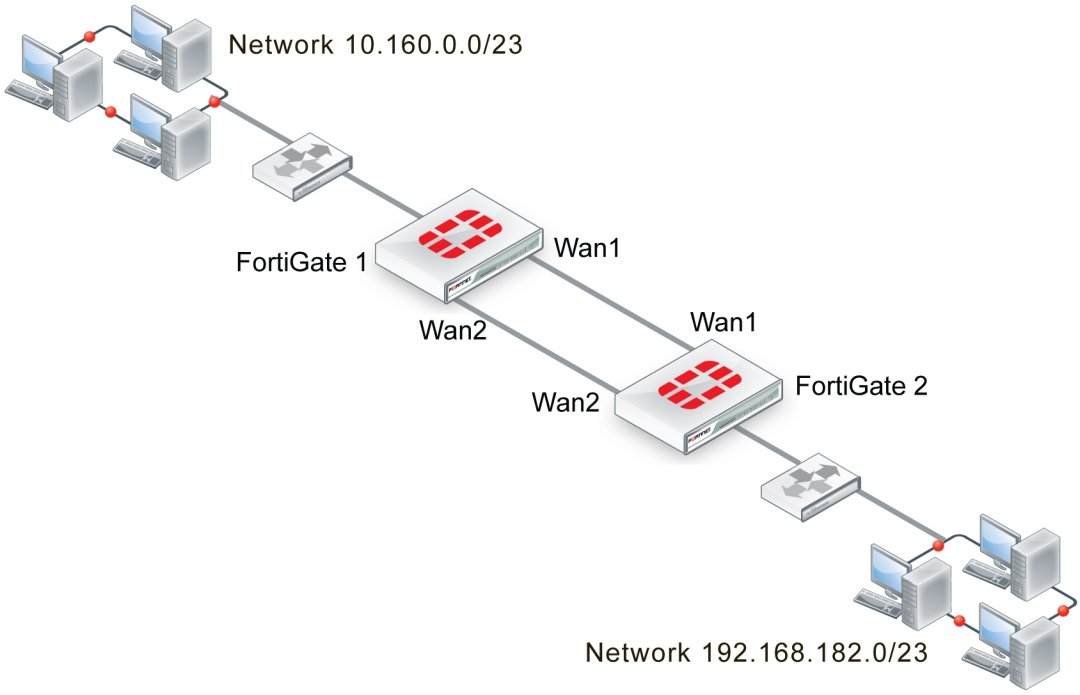
There are two main areas to test in this network configuration; network connectivity, and OSPF routing.

To test the network connectivity, see if computers on the Accounting or R&D networks can access the Internet. If you need to troubleshoot network connectivity, see the FortiOS Handbook Troubleshooting chapter.

To test the OSPF routing, check the routing tables on the FortiGate units to ensure the expected OSPF routes are present. If you need help troubleshooting OSPF routing, see Advanced inter-area OSPF example on page 489.

Controlling redundant links by cost

In this scenario, two FortiGate units have redundant links: one link between their WAN1 interfaces and another between their WAN2 interfaces.



FortiGate 1 should learn the route to network 192.168.182.0 and FortiGate 2 should learn the route to network 10.160.0.0. Under normal conditions, they should learn these routes through the WAN1 link. The WAN2 link should be used only as a backup.

With the default settings, each FortiGate unit learns these routes from both WAN1 and WAN2.

FortiGate 1:

```
FGT1 # get router info ospf neighbor
OSPF process 0:
Neighbor ID Pri State Dead Time Address Interface
10.2.2.2 1 Full/Backup 00:00:33 10.182.0.187 wan1
10.2.2.2 1 Full/Backup 00:00:31 10.183.0.187 wan2
FGT1 # get router info routing-table ospf
O*E2 0.0.0.0/0 [110/10] via 10.183.0.187, wan2, 00:00:01
[110/10] via 10.182.0.187, wan1, 00:00:01
O 192.168.182.0/23 [110/20] via 10.183.0.187, wan2, 00:02:04
[110/20] via 10.182.0.187, wan1, 00:02:04
```

FortiGate 2:

```
FGT2 # get router info ospf neighbor
OSPF process 0:
Neighbor ID Pri State Dead Time Address Interface
10.1.1.1 1 Full/DR 00:00:38 10.182.0.57 wan1
10.1.1.1 1 Full/DR 00:00:38 10.183.0.57 wan2
FGT2 # get router info routing-table ospf
O 10.160.0.0/23 [110/20] via 10.183.0.57, wan2, 00:00:39
[110/20] via 10.182.0.57, wan1, 00:00:39
```

Adjusting the route costs

On both FortiGate units, the cost of the route through WAN2 is adjusted higher so that this route will only be used if the route through WAN1 is unavailable. The default cost is 10. The WAN2 route will be changed to a cost of 200.

On both FortiGate units:

```
config router ospf
   config ospf-interface
      edit "WAN2_higher_cost"
         set cost 200
         set interface "wan2"
      end
```

Now both FortiGate units use only the WAN1 route:

FortiGate 1:

```
FGT1 # get router info routing-table ospf
O*E2 0.0.0.0/0 [110/10] via 10.182.0.187, wan1, 00:00:40
O 192.168.182.0/23 [110/20] via 10.182.0.187, wan1, 00:00:40
```

FortiGate 2:

```
FGT2 # get router info routing-table ospf
O 10.160.0.0/23 [110/20] via 10.182.0.57, wan1, 00:09:37
```

LSDB check on FortiGate 1:

```
FGT1 # get router info ospf database router lsa
Router Link States (Area 0.0.0.0)

   TOS 0 Metric: 200

   Link connected to: a Transit Network
   (Link ID) Designated Router address: 10.182.0.57
   (Link Data) Router Interface address: 10.182.0.187
   Number of TOS metrics: 0
   TOS 0 Metric: 10
```

Verifying route redundancy

Bring down WAN1 and then check the routes on the two FortiGate units.

FortiGate 1:

```
FGT1 # get router info routing-table ospf
FGT1 # get router info routing-table ospf
O*E2 0.0.0.0/0 [110/10] via 10.183.0.187, wan2, 00:00:06
O 192.168.182.0/23 [110/210] via 10.183.0.187, wan2, 00:00:06
```

FortiGate 2:

```
FGT2 # get router info routing-table ospf
O 10.160.0.0/23 [110/210] via 10.183.0.57, wan2, 00:00:14
```

The WAN2 interface is now in use on both units.

Intermediate System to Intermediate System Protocol (IS-IS)

This section describes the Intermediate System to Intermediate System Protocol (IS-IS).

The following topics are included in this section:

IS-IS background and concepts

Intermediate System to Intermediate System Protocol (IS-IS) allows routing of ISO's OSI protocol stack Connectionless Network Service (CLNS). IS-IS is an Interior Gateway Protocol (IGP) not intended to be used between Autonomous Systems (ASes).

Background

IS-IS was developed by Digital Equipment Corporation and later standardized by ISO in 1992 as ISO 19589 (see RFC 1142—note this RFC is different from the ISO version). At roughly the same time, the Internet Engineering Task Force developed OSPF (see Open Shortest Path First (OSPF) on page 2424). After the initial version, IP support was added to IS-IS and this version was called Integrated IS-IS (see RFC 1195). Its widespread use started when an early version of IS-IS was included with BSD v4.3 Linux as the routed daemon. The routing algorithm used by IS-IS, the Bellman–Ford algorithm, first saw widespread use as the initial routing algorithm of the ARPANET.

IS-IS is a link state protocol well-suited to smaller networks that is in widespread use and has near universal support on routing hardware. It is quick to configure, and works well if there are no redundant paths. However, IS-IS updates are sent out node-by-node, so it can be slow to find a path around network outages. IS-IS also lacks good authentication, can not choose routes based on different quality of service methods, and can create network loops if you are not careful. IS-IS uses Djikstra's algorithm to find the best path, like OSPF.

While OSPF is more widely known, IS-IS is a viable alternative to OSPF in enterprise networks and ISP infrastructures, largely due to its native support for IPv6 and its non-disruptive methods for splitting, merging, migrating, and renumbering network areas.

The FortiGate implementation supports IS-IS for IPv4 (see RFCs 1142 and 1162), but does not support IS-IS for IPv6 (although this technically can be achieved using the ZebOS routing module).

How IS-IS works

As one of the original modern dynamic routing protocols, IS-IS is straightforward. Its routing algorithm is not complex, there are some options to allow fine tuning, and it is straightforward to configure IS-IS on FortiGate units.

From RFC 1142:

> *The routing algorithm used by the Decision Process is a shortest path first (SPF) algorithm. Instances of the algorithm are run independently and concurrently by all intermediate systems in a routing domain. IntraDomain routing of a PDU occurs on a hop-by-hop basis: that is, the algorithm determines only the next hop, not the complete path, that a data PDU will take to reach its destination.*

IS-IS versus static routing

IS-IS was one of the earliest dynamic routing protocols to work with IP addresses. As such, it is not as complex as more recent protocols. However, IS-IS is a big step forward from simple static routing.

While IS-IS may be slow in response to network outages, static routing has zero response. The same is true for convergence—static routing has zero convergence. Both IS-IS and static routing have the limited hop count, so it is neither a strength nor a weakness.

TLV

IS-IS uses *type-length-variable (TLV)* parameters to carry information in Link-State PDUs (LSPs). Each IS-IS LSP consists of a variable-length header to which TLVs are appended in order to extend IS-IS for IP routing. The TLV field consists of one octet of type (T), one octet of length (L), and "L" octets of Value (V). They are included in all of the IS-IS Packet types. For a complete breakdown of the LSP, see LSP structure on page 505.

In IS-IS, TLVs are used to determine route-leaking and authentication, and are also used for IPv4 and IPv6 awareness and reachability.

- To determine which TLVs are responsible for route-leaking, see Default routing on page 507.
- To determine which TLVs are responsible for authentication, see Authentication on page 509.

For a complete list of reserved TLV codepoints, refer to RFC 3359.

LSP structure

It is difficult to fully understand a routing protocol without knowing what information is carried in its packets. Knowing how routers exchange each type of information will help you better understand the IS-IS protocol and will allow you to configure your network more appropriatey.

This section provides information on the contents of the IS-IS LSP. LSPs describe the network topology and can include IP routes and checksums.

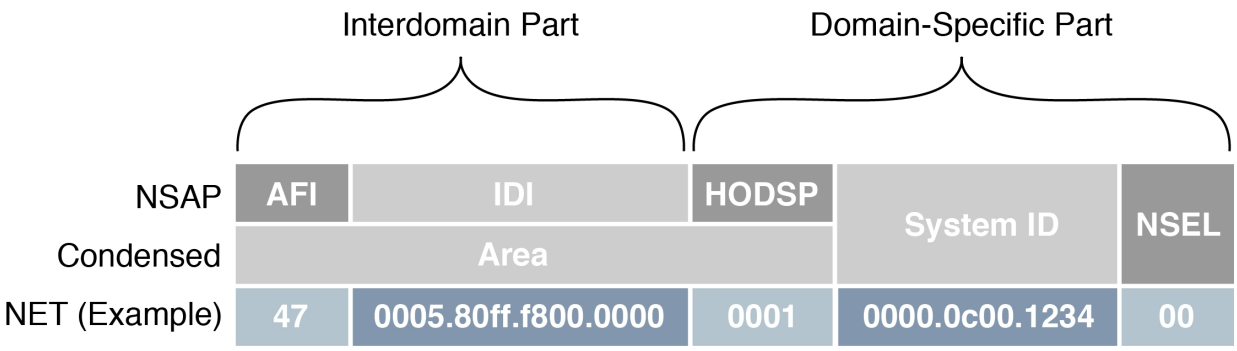
NSAP and NET

IS-IS routing protocol utilizes ISO network addressing to identify network interfaces. The addresses are known as Network Service Access Points (NSAPs). In general, IS-IS routers consist of only one NSAP, whereas IP addressing requires one IP address per interface.

In IS-IS, the NSAP address is translated into a Network Entity Title (NET), which is the same as the NSAP but can differentiate end systems by way of a byte called the *n-selector* (NSEL). In order for adjacencies to form in IS-IS, the NSEL must necessarily be set to zero, to indicate "this system". The total NET can be anywhere between 8 and 20 bytes long due to the support for variable length area addressing.

The following diagram identifies the individual parts of the NSAP, with explanations below.

NSAP and NET example



AFI — The *Authority and Format Identifier (AFI)* specifies the format of the addressing family used. IS-IS is designed to carry routing information for several different protocols. Each entry has an address family identifier that identifies the globally unique Interdomain Part (IDP). For example, 49 is the AFI for private addresses, whereas 47 is the AFI for international organizations.

IDI — The *Initial Domain Identifier (IDI)* identifies the routing domain within an interconnected network. The length of the IDI is typically determined by the AFI. If you are using an AFI of 49, you do not need to specify an IDI, since the network is private.

HODSP — The *High Order Domain-Specific Part (HODSP)* identifies the unique address within a specific routing domain. Together, the AFI, IDI, and HODSP define the area address. All of the nodes within an area must have the same area address.

System ID — The *System ID* represents the 6-8 byte router identifier. The ID could be Media Access Control (MAC) format, as in the example above, or a static length IP address expressed in binary-coded decimal (BCD) format.

NSEL — The *n-selector (NSEL)*, as previously described, identifies the network layer transport service and must always be set to zero for IS-IS NETs.

Parts and terminology of IS-IS

Before you can understand how IS-IS functions, you need to understand some of the main concepts and parts of IS-IS.

This section includes:

- DIS election and pseudonode LSP
- Packet types
- Default routing
- Timer options
- Authentication

DIS election and pseudonode LSP

In IS-IS routing protocol, a single router is chosen to be the designated intermediate system (DIS). The election of the DIS is determined automatically and dynamically on the LAN depending on highest interface priority and the subnetwork point of attachment (SNPA). The FortiGate is typically the DIS, and each router in its LAN is an intermediate system (IS).

Unlike OSPF, which elects a designated router (DR) and backup designated router (BDR), the DIS has no backup and determines the election of a new DIS whenever a router is added to the LAN or whenever the current DIS drops. A backup DIS is irrelevant since all of the routers on an IS-IS system are synchronized, and the short Hello interval used by the DIS quickly detects failures and the subsequent replacement of the DIS.

Synchronization of all the nodes in an IS-IS area could prove troublesome when updating the network infrastructure, and would demand ever-increasing resources each time a new router is added (at an exponential scale). For this purpose the DIS creates a pseudonode, which is essentially a virtual, logical node representing the LAN. The pseudonode requests adjacency status from all the routers in a multi-access network by sending IS-IS Hello (IIH) PDUs to Level 1 and Level 2 routers (where Level 1 routers share the same address as the DIS and Level 2 routers do not). Using a pseudonode to alter the representation of the LAN in the link-state database (LSD) greatly reduces the amount of adjacencies that area routers have to report. In essence, a pseudonode *collapses* a LAN topology, which allows a more linear scale to link-state advertising.

In order to maintain the database synchronization, the DIS periodically sends complete sequence number packets (CSNPs) to all participating routers.

Packet types

Four general packet types (PDUs) are communicated through IS-IS, appearing at both Level 1 and Level 2. They are described below.

Intermediate System-to-Intermediate System Hello (IIH) PDU — As mentioned previously, the IIH PDU, or Hello packet, detects neighboring routers and indicates to the pseudonode the area's adjacency mesh. The Hello packet, flooded to the multicast address, contains the system ID of the sending router, the holding time, the circuit type of the interface on which the PDU was sent, the PDU length, the DIS identifier, and the interface priority (used in DIS election). The Hello packet also informs its area routers that it is the DIS.

Hello packets are padded to the maximum IS-IS PDU size of 1492 bytes (the full MTU size) to assist in the detection of transmission errors with large frames or with MTU mismatches between adjacencies.

The DIS typically floods Hello packets to the entire LAN every three seconds.

Link-state PDU (LSP) — The LSP contains information about each router in an area and its connected interfaces. LSPs are refreshed periodically and acknowledged on the network by way of sequence number PDUs. If new LSP information is found, based on the most recent complete sequence number PDU (CSNP), then out-of-date entries in the link-state database (LSDB) are removed and the LSDB is updated.

For a more detailed breakdown of the LSP, see LSP structure on page 505.

Complete sequence number PDU (CSNP) — CSNPs contain a list of all LSPs in the current LSDB. The CSNP informs other area routers of missing or outdated links in the adjacency mesh. The receiving routers then use this information to update their own database to ensure that all area routers converge.

In contrast to Hello packets, CSNPs are sent every ten seconds and only between neighbors. In other words, they are never flooded.

Partial sequence number PDU (PSNP) — PSNPs are used to request and acknowledge LSP information from an adjacency. When a router compares a CSNP with its local database and determines a discrepancy, the router requests an updated LSP using a PSNP. Once received, the router stores the LSP in its local database and responds to the DIS with acknowledgement.

Default routing

The default route is used if either there are no other routes in the routing table or if none of the other routes apply to a destination. Including the gateway in the default route gives all traffic a next-hop address to use when leaving the local network. The gateway address is normally another router on the edge of the local network.

FortiGate units come with a default static route with an IPv4 address of 0.0.0.0, an administration distance of 10, and a gateway IPv4 address. Beginner administrators can use the default route settings until a more advanced configuration is warranted.

By default, all routes are displayed in the Routing Monitor list. To display the routes in the routing table, go to **Monitor > Routing Monitor**.

Route leaking

Route leaking is the term used to describe the bi-directional flow of information between internal and external routing interfaces. By default, IS-IS leaks routing information from a Level 1 area into a Level 2 area. In order to

leak Level 2 routing information into a Level 1 area, you must configure an export policy. Whether or not a route is leaked is determined by the ATT bit, using TLV 128 (for internal IP reachability) and TLV 130 (for external IP address information). For more information on TLVs, see Troubleshooting IS-IS on page 510.

To configure IS-IS route leaking, use the following CLI commands.

1. On a Level 1-2 router:
```
config router isis
   set redistribute-l2 enable
end
```
2. You can use the following commands to show the results
```
get router info routing-table isis
get router info isis route
```

Default information originate option

Enabling default-information-originate generates and advertises a default route into the FortiGate unit's IS-IS-enabled networks. The generated route may be based on routes learned through a dynamic routing protocol, routes in the routing table, or both. IS-IS does not create the default route unless you use the `always` option.

Select **Disable** if you experience any issues or if you wish to advertise your own static routes into IS-IS updates.

The CLI commands associated with default information originate include:

```
config router isis
   set default-originate
end
```

Timer options

IS-IS uses various timers to regulate its performance including a garbage timer, update timer, and timeout timer. The FortiGate unit default timer settings (30, 180, and 120 seconds respectively) are effective in most configurations—if you change these settings, ensure that the new settings are compatible with local routers and access servers.

You can configure the three IS-IS timers in the CLI, using the following commands:

```
config router isis
   set garbage-timer
   set update-timer
   set timeout-timer
end
```

You will find more information on each timer below.

Update timer

The update timer determines the interval between routing updates. Generally, this value is set to 30 seconds. There is some randomness added to help prevent network traffic congestion, which could result from all routers simultaneously attempting to update their neighbors. The update timer should be at least three times smaller than the timeout timer, otherwise you will experience an error.

If you are experiencing significant traffic on your network, you can increase this interval to send fewer updates per minute. However, ensure you increase the interval for all the routers on your network or you will experience timeouts that will degrade your network speed.

Timeout timer

The timeout timer is the maximum amount of time (in seconds) that a route is considered reachable while no updates are received for the route. This is the maximum time the DIS will keep a reachable route in the routing table while no updates for that route are received. If the DIS receives an update for the route before the timeout period expires, the timer is restarted. The timeout period should be at least three times longer than the update period, otherwise you will experience an error.

If you are experiencing problems with routers not responding in time to updates, increase this timer. However, remember that longer timeout intervals result in longer overall update periods — it may be considerable time before the DIS is done waiting for all the timers to expire on unresponsive routes.

Garbage timer

The garbage timer is the amount of time (in seconds) that the DIS will advertise a route as being unreachable before deleting the route from the routing table. If this timer is shorter, it will keep more up-to-date routes in the routing table and remove old ones faster. This results in a smaller routing table which is useful if you have a very large network, or if your network changes frequently.

Authentication

In routing protocols, it is typically desireable to establish authentication rules that prevent malicious and otherwise unwanted information from being injected into the routing table. IS-IS routing protocol utilizes TLV 10 to establish authentication. For more information on TLVs, see TLV on page 505.

Initially, IS-IS used plain Clear Text to navigate the authentication rules, but this was found to be insecure since the Clear Text packets were unencrypted and could be exposed to packet sniffers. As per RFC 3567, HMAC-MD5 and Enhanced Clear Text authentication features were introduced to IS-IS, both of which encrypt authentication data, making them considerably more secure than using plain Clear Text authentication.

HMAC-MD5 authentication

Hashed Message Authentication Codes - Message Digest 5 (HMAC-MD5) is a mechanism for applying a cryptographic hash function to the message authentication process. It is applied at both Level 1 and Level 2 routing. In IS-IS, an HMAC-MD5 can be applied to each type of LSP, on different interfaces, and with different passwords.

Authentication data is hashed using an AH (Authentication Header) key. From RFC 2085:

> *The "AH Key" is used as a shared secret between two communicating parties. The Key is not a "cryptographic key" as used in a traditional sense. Instead, the AH key (shared secret) is hashed with the transmitted data and thus, assures that an intervening party cannot duplicate the authentication data. [...] Implementation should, and as frequently as possible, change the AH key. Keys need to be chosen at random, or generated using a cryptographically strong pseudo-random generator seeded with a random seed."*

Clear Text authentication uses the configuration commands `area-password` and `domain-password` for authentication, but when migrating from Clear Text authentication to HMAC-MD5, these command settings are automatically overwritten.

By the year 2005, the MD5 hash function had been identified as vulnerable to collision search attacks and various weaknesses. While such vulnerabilities do not compromise the use of MD5 within HMAC, administrators need to be aware of potential developments in cryptanalysis and cryptographic hash functions in the likely event that the underlying hash function needs to be replaced.

Enhanced Clear Text authentication

Enhanced Clear Text authentication is an extension to Clear Text authentication that allows the encryption of passwords as they are displayed in the configuration. It includes a series of authentication mode commands and an authentican key chain, and allows for more simple password modification and password management. Enhanced Clear Text authentication also provides for smoother migration to and from changing authentication types. Intermediate systems continue to use the original authentication method until all the area routers are updated to use the new method.

Authentication key chain

A key chain is a list of one or more authentication keys including the send and receive lifetimes for each key. Keys are used for authenticating routing packets only during the specified lifetimes. A router migrates from one key to the next according to the scheduled send and receive lifetimes. If an active key is unavailable, then the PDU is automatically discarded.

From RFC 5310:

> *It should be noted that the cryptographic strength of the HMAC depends upon the cryptographic strength of the underlying hash function and on the size and quality of the key.*

Troubleshooting IS-IS

This section includes:

- Routing loops
- Split horizon and Poison reverse updates

Routing loops

Normally in routing, a path between two addresses is chosen and traffic is routed along that path from one address to the other. When there is a routing loop, that normal path doubles back on itself creating a loop. When there are loops, the network has problems.

A routing loop happens when a normally functioning network has an outage, and one or more routers are offline. When packets encounter this, an alternate route is attempted to maneuver around the outage. During this phase it is possible for a route to be attempted that involves going back a hop, and trying a different hop forward. If that hop forward is blocked by the outage as well, a hop back and possibly the original hop forward may be selected. You can see if this continues, how it can consume not only network bandwidth but also many resources on those routers affected. The worst part is this situation will continue until the network administrator changes the router settings, or the downed routers come back online.

Routing loop effect on the network

In addition to this “traffic jam” of routed packets, every time the routing table for a router changes that router sends an update out to all of the IS-IS routers connected to it. In a network loop, its possible for a router to change its routes very quickly as it tries and fails along these new routes. This can quickly result in a flood of updates being sent out, which can effectively grind the network to a halt until the problem is fixed.

How can you spot a routing loop

Any time network traffic slows down, you will be asking yourself if it is a network loop or not. Often slowdowns are normal, they are not a full stoppage, and normal traffic resumes in a short period of time.

If the slow down is a full halt of traffic or a major slowdown does not return to normal quickly, you need to do serious troubleshooting quickly.

Some methods to troubleshoot your outage include:

- Checking your logs
- Using SNMP network monitoring
- Using Link Health Monitor and e-mail alerts
- Looking at the packet flow

If you aren't running SNMP, dead gateway detection, or you have non-Fortinet routers in your network, you can use networking tools such as ping and traceroute to define the outage on your network and begin to fix it.

Checking your logs

If your routers log events to a central location, it can be easy to check the logs for your network for any outages.

On your FortiGate unit, go to **Log & Report > Log & Archive Access**. You will want to look at both event logs and traffic logs. Events to look for will generally fall under CPU and memory usage, interfaces going offline (due to dead gateway detection), and other similar system events.

Once you have found and fixed your network problem, you can go back to the logs and create a report to better see how things developed during the problem. This type of forensics analysis can better help you prepare for next time.

Using SNMP network monitoring

If your network had no problems one minute and slows to a halt the next, chances are something changed to cause that problem. Most of the time an offline router is the cause, and once you find that router and bring it back online, things will return to normal.

If you can enable a hardware monitoring system such as SNMP or sFlow on your routers, you can be notified of the outage and where it is exactly as soon as it happens.

Ideally you can configure SNMP on all your FortiGate routers and be alerted to all outages as they occur.

To use SNMP to detect potential routing loops

1. Go to **System > SNMP**.
2. Enable **SNMP Agent**.
3. Optionally enter the **Description**, **Location**, and **Contact** information for this device for easier location of the problem report.
4. In either **SNMP v1/v2c** section or **SNMP v3** section, as appropriate, select **Create New**.
5. Enter the **Community Name** that you want to use.
6. In **Hosts**, select Add to add an IP address where you will be monitoring the FortiGate unit. You can add up to 8 different addresses.
7. Ensure that ports 161 and 162 (SNMP queries and traps) are allowed through your security policies.
8. In **SNMP Event**, select the events you want to be notified of. For routing loops this should include **CPU Overusage**, **Memory Low**, and possibly **Log disk space low**. If there are problems, the log will be filling up quickly, and the FortiGate unit's resources will be overused.
9. Select **OK**.

10. Configure SNMP host (manager) software on your administration computer. This will monitor the SNMP information sent out by the FortiGate unit. Typically you can configure this software to alert you to outages or CPU spikes that may indicate a routing loop.

Using Link Health Monitor and e-mail alerts

Another tool available to you on FortiGate units is the Link Health Monitor, useful for dead gateway detection. This feature allows the FortiGate unit to ping a gateway at regular intervals to ensure it is online and working. When the gateway is not accessible, that interface is marked as down.

To detect possible routing loops with Link Health Monitor

Use the following command to configure dead gateway detection:

```
config system link-monitor
   edit "test"
      set srcintf "internal4"
      set server "8.8.8.8"
      set interval 5
      set failtime 1
   end
```

Set the `Interval` (how often to send a ping) and `failtime` (how many lost pings is considered a failure). A smaller interval and smaller number of lost pings will result in faster detection, but will create more traffic on your network.

You may also want to log CPU and Memory usage as a network outage will cause your CPU activity to spike.

If you have VDOMs configured, you will have to enter the basic SMTP server information in the Global section, and the rest of the configuration within the VDOM that includes this interface.

After this configuration, when this interface on the FortiGate unit cannot connect to the next router, the FortiGate unit will bring down the interface and alert you with an email to the outage.

Looking at the packet flow

If you want to see what is happening on your network, look at the packets travelling on the network. In this situation, you are looking for routes that have metrics higher than 15 as that indicates they are unreachable. Ideally if you debug the flow of the packets, and record the routes that are unreachable, you can create an accurate picture of the network outage.

Action to take on discovering a routing loop

Once you have mapped the problem on your network, and determined it is in fact a routing loop there are a number of steps to take in correcting it.

1. Get any offline routers back online. This may be a simple reboot, or you may have to replace hardware. Often this first step will restore your network to its normal operation, once the routing tables finish being updated.
2. Change your routing configuration on the edges of the outage. Even if step 1 brought your network back online, you should consider making changes to improve your network before the next outage occurs. These changes can include configuring features like holddowns and triggers for updates, split horizon, and poison reverse updates.

Split horizon and Poison reverse updates

Split horizon is best explained with an example. You have three routers linked serially, let's call them A, B, and C. A is only linked to B, C is only linked to B, and B is linked to both A and C. To get to C, A must go through B. If the link to C goes down, it is possible that B will try to use A's route to get to C. This route is A-B-C, so it will not work. However, if B tries to use it this begins an endless loop.

This situation is called a split horizon because from B's point of view the horizon stretches out in each direction, but in reality it only is on one side.

Poison reverse is the method used to prevent routes from running into split horizon problems. Poison reverse "poisons" routes away from the destination that use the current router in their route to the destination. This "poisoned" route is marked as unreachable for routers that cannot use it. In IS-IS this means that route is marked with a distance of 16.

Simple IS-IS example

This is an example of a typical medium-sized network configuration using IS-IS routing.

Imagine a company with four FortiGate devices connected to one another. A FortiGate at one end of the network connects to two routers, each with its own local subnet; one of these routers uses OSPF and the other uses RIP.

Your task is to configure the four FortiGates to route traffic and process network updates using IS-IS, such that the farthest FortiGate (see 'FGT4' in Network layout and assumptions on page 514) receives route updates for the two routers at the opposite end of the network. Furthermore, FGT4 has been given a loopback subnet that must be identified by the router running RIP.

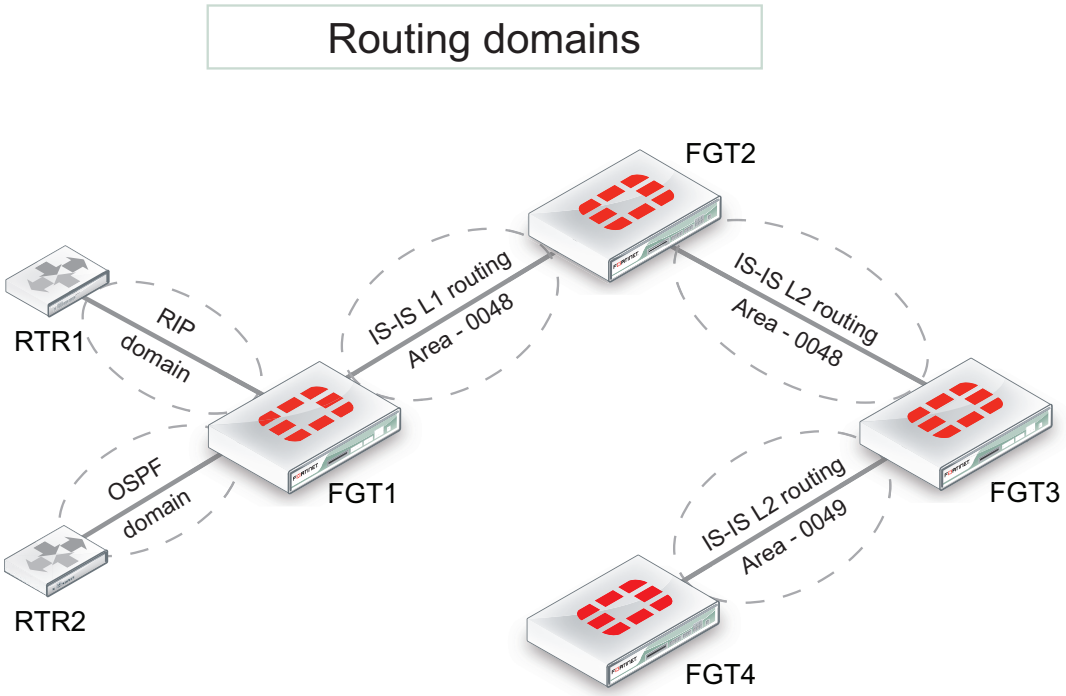
Since the internal networks use OSPF and RIP, those protocols will need to be redistributed through the IS-IS network. To keep the example simple, there will be no authentication of router traffic.

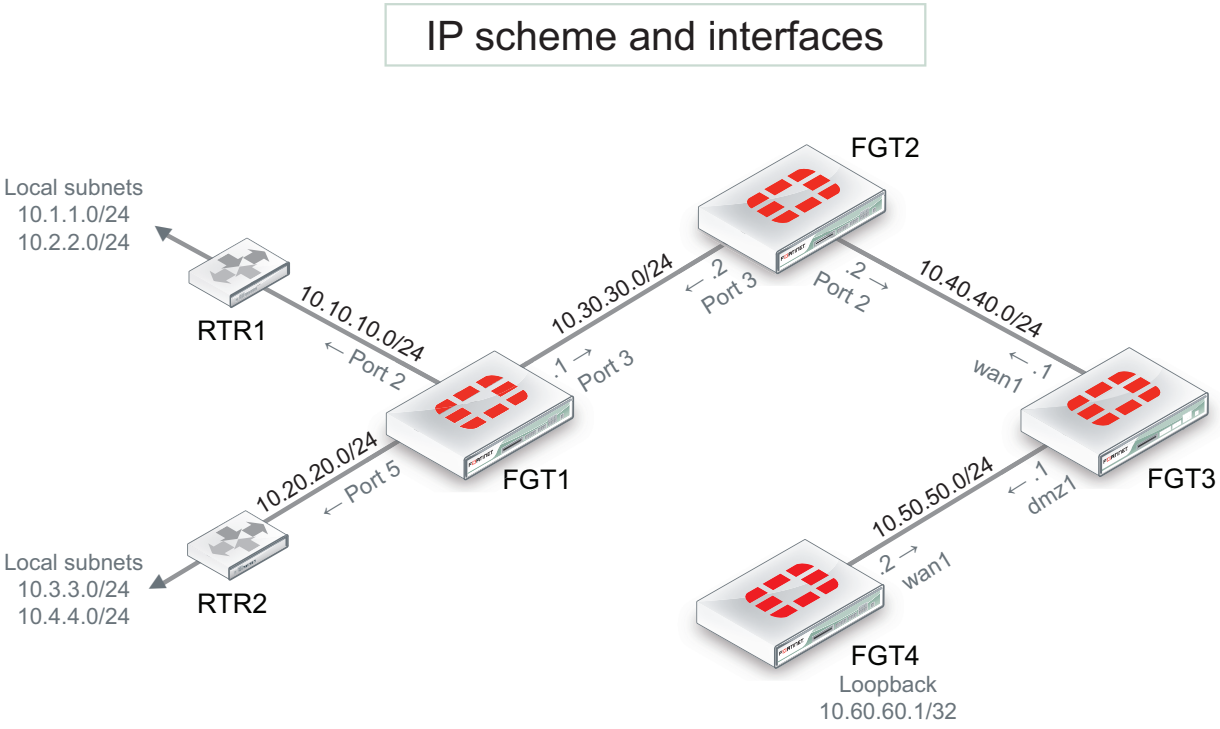
With IS-IS properly configured in this example, if a router fails or temporarily goes offline, the route change will propagate throughout the system.

This section includes the following topics:

- Network layout and assumptions
- Expectations
- CLI configuration
- Verification
- Troubleshooting

Network layout and assumptions





- It is assumed that each FortiGate is operating in NAT mode, running FortiOS 4.0MR2+.
- All interfaces have been previously assigned and no static routes are required.

- The AFI (Authority and Format Identifier) used is 49 : Locally administered (private).
- The Area identifiers are 0048 and 0049.

Expectations

- FGT4 must get the IS-IS route updates for RTR1 and RTR2 local subnets (10.1.1.0, 10.2.2.0, 10.3.3.0, 10.4.4.0).
- RTR1 must receive (via RIP2) the loopback subnet of FGT4 (10.60.60.1/32).

CLI configuration

The following CLI configuration occurs on each FortiGate (as identified), including only the relevant parts.

FGT1

```
config router isis
   config isis-interface
      edit "port3"
         set circuit-type level-1
         set network-type broadcast
         set status enable
      next
   end
   config isis-net
      edit 1
         set net 49.0048.1921.6818.2136.00
      next
   end
   config redistribute "connected"
   end
   config redistribute "rip"
      set status enable
      set level level-1
   end
   config redistribute "ospf"
      set status enable
      set level level-1
   end
end
config router rip
   config interface
      edit "port2"
         set receive-version 2
         set send-version 2
      next
   end
   config network
      edit 1
         set prefix 10.10.10.0 255.255.255.0
      next
   end
   config redistribute "isis"
      set status enable
   end
end
```

FGT2

```
config router isis
   config isis-interface
      edit "port3"
         set circuit-type level-1
         set network-type broadcast
         set status enable
      next
      edit "port2"
         set network-type broadcast
         set status enable
      next
   end
   config isis-net
      edit 1
         set net 49.0048.1221.6818.2110.00
      next
   end
   set redistribute-l1 enable
   set redistribute-l2 enable
end
```

FGT3

```
config router isis
   set is-type level-2-only
      config isis-interface
         edit "wan1"
            set network-type broadcast
            set status enable
         next
         edit "dmz1"
            set network-type broadcast
            set status enable
         next
      end
      config isis-net
         edit 1
            set net 49.0048.1921.6818.2108.00
         next
         edit 2
            set net 49.0049.1921.6818.2108.00
         next
      end
end
```

FGT4

```
config router isis
   set is-type level-2-only
      config isis-interface
         edit "wan1"
            set network-type broadcast
            set status enable
```

```
            next
        end
        config isis-net
            edit 1
                set net 49.0049.1721.0160.1004.00
            next
        end
        config redistribute "connected"
            set status enable
        end
    end
```

Verification

Once the network has been configured, you need to test that it works as expected. Use the following CLI commands on the devices indicated.

Verifying if RTR1 receives loopback subnet of FGT4

```
(RTR1) # get router info routing-table all
```

Result:

```
C    10.1.1.0/24 is directly connected, vlan1
C    10.2.2.0/24 is directly connected, vlan2
C    10.10.10.0/24 is directly connected, dmz1
R    10.40.40.0/24 [120/2] via 10.10.10.1, dmz1, 00:04:07
R    10.50.50.0/24 [120/2] via 10.10.10.1, dmz1, 00:04:07
R    10.60.60.1/32 [120/2] via 10.10.10.1, dmz1, 00:04:07
```

(*) If required, filtering out 10.50.50.0 and 10.40.40.0 from the routing table could be done with a route-map.

Verification on FGT2, which is the border between L1 and L2 routing levels; looking at IS-IS information

```
FGT2 # get router info isis interface
```

Result:

```
port2 is up, line protocol is up
Routing Protocol: IS-IS ((null))
Network Type: Broadcast
Circuit Type: level-1-2

IPv4 interface address:
Level-2 Metric: 10/10, Priority: 64, Circuit ID: 1721.0160.1004.01
Number of active level-2 adjacencies: 1
Next IS-IS LAN Level-2 Hello in 7 seconds

FGT3 # get router info isis neighbor
```

Result:

System Id	Interface	SNPA	State	Holdtime	Type	Protocol
1221.6818.2110	wan1	0009.0f85.ad8c	Up	8	L2	IS-IS
1721.0160.1004	dmz1	0009.0f52.7704	Up	8	L2	IS-IS

Verification on FGT4 that the remote subnets from RTR1 and RTR2 are in the routing table and learned with IS-IS

```
FGT4 # get router info routing-table all
```

Result:

```
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
O - OSPF, IA - OSPF inter area
     N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
     E1 - OSPF external type 1, E2 - OSPF external type 2
     i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
     * - candidate default
i L2 10.1.1.0/24 [115/30] via 10.50.50.1, wan1, 00:12:46
    i L2 10.2.2.0/24 [115/30] via 10.50.50.1, wan1, 00:12:46
    i L2 10.3.3.0/24 [115/30] via 10.50.50.1, wan1, 00:12:46
    i L2 10.4.4.0/24 [115/30] via 10.50.50.1, wan1, 00:12:46
i L2 10.10.10.0/24 [115/30] via 10.50.50.1, wan1, 00:12:46
    i L2 10.11.11.0/24 [115/30] via 10.50.50.1, wan1, 00:12:46
    i L2 10.20.20.0/24 [115/30] via 10.50.50.1, wan1, 00:12:46
```

```
        i L2 10.30.30.0/24 [115/30] via 10.50.50.1, wan1, 00:13:55
        i L2 10.40.40.0/24 [115/20] via 10.50.50.1, wan1, 00:15:30
    C 10.50.50.0/24 is directly connected, wan1
        C 10.60.60.1/32 is directly connected, loopback
```

Troubleshooting

The following diagnose commands are available for further IS-IS troubleshooting and will display all IS-IS activity (sent and received packets):

```
FGT # diagnose ip router isis level info
FGT # diagnose ip router isis all enable
FGT # diagnose debug enable
```

…to stop the debug type output:

```
FGT # diagnose ip router isis level none
```

Output and interpretation depends on the issue faced. You can provide this information to TAC if you open a support ticket.

Chapter 4 - Authentication

This Handbook chapter contains the following sections:

Introduction to authentication describes some basic elements and concepts of authentication.

Authentication servers describes external authentication servers, where a FortiGate unit fits into the topology, and how to configure a FortiGate unit to work with that type of authentication server.

Users and user groups describes the different types of user accounts and user groups. Authenticated access to resources is based on user identities and user group membership. Two-factor authentication methods, including FortiToken, provide additional security.

Managing Guest Access explains how to manage temporary accounts for visitors to your premises.

Configuring authenticated access provides detailed procedures for setting up authenticated access in security policies and authenticated access to VPNs.

Captive portals describes how to authenticate users through a web page that the FortiGate unit presents in response to any HTTP request until valid credentials are entered. This can be used for wired or WiFi network interfaces.

Certificate-based authentication describes authentication by means of X.509 certificates.

Single Sign-On using a FortiAuthenticator unit describes how to use a FortiAuthenticator unit as an SSO agent that can integrate with external network authentication systems such as RADIUS and LDAP to gather user logon information and send it to the FortiGate unit. Users can also log on through a FortiAuthenticator-based web portal or the FortiClient SSO Mobility Agent.

Single Sign-On to Windows AD describes how to set up Single Sign-On in a Windows AD network by configuring the FortiGate unit to poll domain controllers for information user logons and user privileges.

Agent-based FSSO describes how to set up Single Sign-On in Windows AD, Citrix, or Novell networks by installing Fortinet Single Sign On (FSSO) agents on domain controllers. The FortiGate unit receives information about user logons and allows access to network resources based on user group memberships.

SSO using RADIUS accounting records describes how to set up Single Sign-On in a network that uses RADIUS authentication. In this configuration, the RADIUS server send RADIUS accounting records to the FortiGate unit when users log on or off the network. The record includes a user group name that can be used in FortiGate security policies to determine which resources each user can access.

Monitoring authenticated users describes FortiOS authenticated user monitor screens.

Examples and Troubleshooting provides configuration examples and troubleshooting suggestions.

Whats New in FortiOS 5.4

This chapter describes new authentication features added to FortiOS 5.4.0 and FortiOS 5.4.1.

FortiOS 5.4.1

These features first appeared in FortiOS 5.4.1.

Support for changing a local certificate's password (297660)

Administrators can set a password through the CLI when generating a certificate request.

RADIUS CoA support (309499)

The following RADIUS CoA (Change of Authorization) CLI syntax has been added:

- Set the name of the FortiAP connected to the FortiGate as a location identifier.

CLI syntax

```
config system global
   set alias
```

- Set URL of external authentication logout server.

CLI syntax

```
config vdom
   edit root
      config wireless-controller vap
         edit <example>
            set security captive-portal
            set external-logout
```

- Set URL of external authentication logout server.

CLI syntax

```
config vdom
   edit root
      config system interface
         edit <example>
            set security captive-portal
            set security-external-logout
```

- Set class name(s) included in an Access-Accept message.

CLI syntax

```
config vdom
   edit root
      config user radius
```

```
edit accounting
   set class <"A1=aaa" "B2=bbb" "C3=ccc">
```

You can now import PKCS12 certificates from the CLI (309934)

The following CLI syntax can be entered to import a local certificate file:

CLI Syntax

```
execute vpn certificate local import tftp <file name> <tftp ip address> <file type> <Enter
    for 'cer'>|<password for 'p12'>
```

For example:

```
execute vpn certificate local import tftp FGTF-extern.p12 10.1.100.253 p12 123456
```

FortiOS 5.4.0

These features first appeared in FortiOS 5.4.0.

RADIUS Framed-IP into accounting packets (234003 189828)

RADIUS attributes, including NAS-IP-Address, Called-Station-ID, Framed-IP-Address, and Event-Timestamp, are supported.

Include RADIUS attribute CLASS in all accounting requests (290577)

RADIUS attribute CLASS in accounting requests for firewall, WiFi, and proxy authentication is now supported. RADIUS attribute CLASS is returned in Access-Accept message and it is added to all accounting requests.

- If updating to 5.4.1, see above (309499).

Certificate-related changes (263368)

Fortinet_factory certificate has been re-signed with an expiration date of 2038 and it is used instead of fortinet_factory2, which has been removed.

Improvements and changes to per-VDOM certificates (276403 267362)

The CA and local certificate configuration is now available per-VDOM. When an admin uploads a certificate to a VDOM, it will only be accessible inside that VDOM. When an admin uploads a certificate to global, it will be accessible to all VDOMs and global.

There are factory default certificates such as Fortinet_CA_SSL, Fortinet_SSL, PositiveSSL_CA, Fortinet_Wifi, and Fortinet_Factory, these certificates are moved to per-VDOM and automatically generated when a new VDOM is created.

The Fortinet_Firmware certificate has been removed and all the attributes that use Fortinet_Firmware now use Fortinet_Factory.

CLI Changes

Two new attributes `range` and `source` have been added:

`range` can be global or per-VDOM, if the certificate file is imported from global, it is a global certificate. If the certificate file is imported from a VDOM, it is VDOM certificate.

`source` can be `factory`, `user` or `fortiguard`:

`factory`: The factory certificate file with FortiOS version, this includes: Fortinet_CA_SSL, Fortinet_SSL, PositiveSSL_CA, Fortinet_Wifi, Fortinet_Factory.

`user`: Certificate file imported by the user.

`fortiguard`: Certificate file imported from FortiGuard.

```
config certificate local
   edit Fortinet_Factory
      set range global/vdom
      set source factory/user/fortiguard
   end
end
```

GUI Changes

Global and per-VDOM certificate configuration includes **view details**, **download**, **delete**, and **import** certificate.

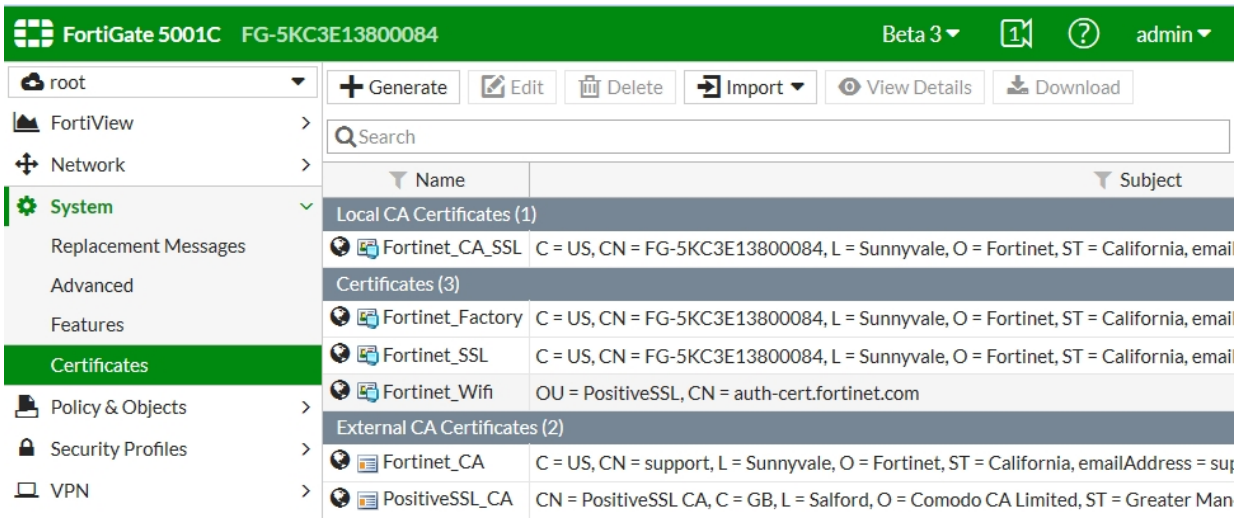
A **Source** and a **Status** columns have been added.

A global icon for **Name** column when VDOMs are enabled is added to show that the certificate is global.

A new VDOM now has the following default certificates: Fortinet_CA_SSL, Fortinet_Factory, Fortinet_SSL, Fortinet_Wifi, Fortinet_CA, and PositiveSSL_CA. These certificates are created automatically when the VDOM is created and every VDOM will have its own individual versions of these certificates.

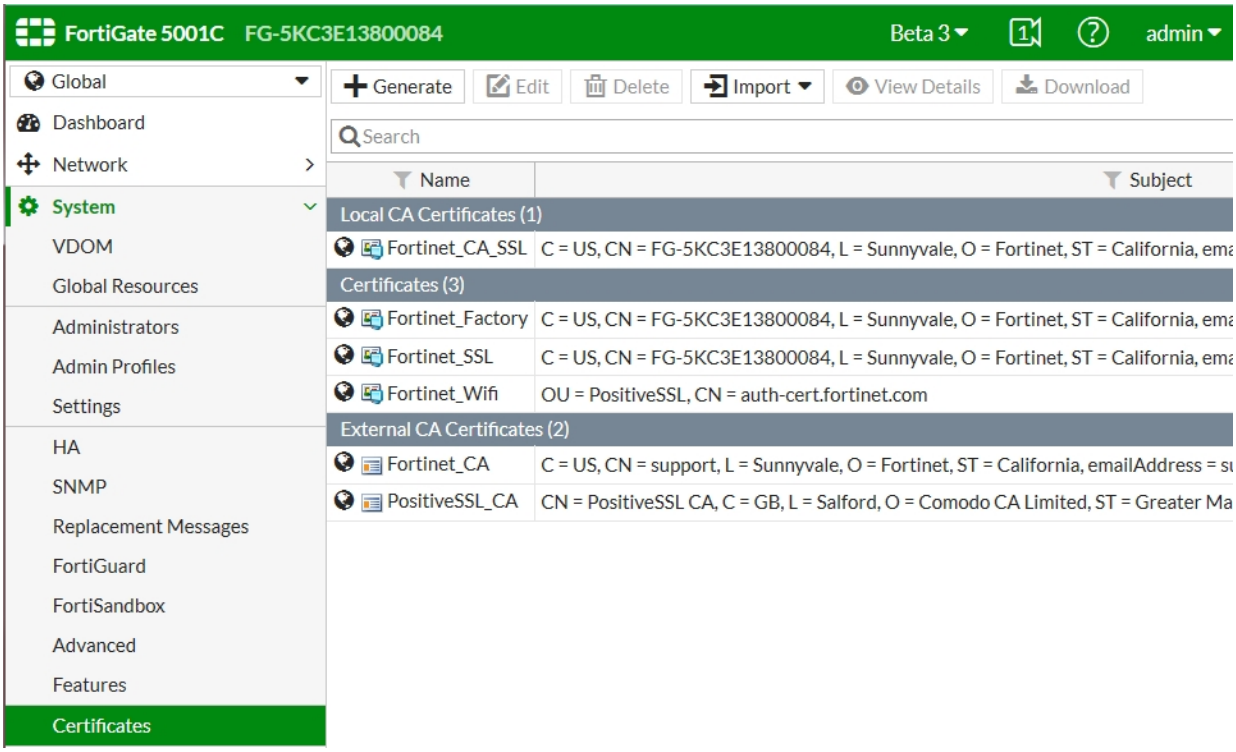
The Fortinet_firmware certificate has been removed. All default configurations that formerly used the Fortinet_ firmware certificate now use the Fortinet_Factory certificate.

Default root VDOM certificates



Certificates with the same names are also available from the global configuration. These are generated when you turn on VDOMs.

Default global certificates



Adding certificates to VDOMs and to the global configuration

If an administrator adds a certificate to a VDOM the certificate will only be available for that VDOM. If an administrator adds a certificate to the global configuration it will available for all VDOMs.

Guest user enhancements (291042)

The password policy profile for guest Admin is improved. This is a CLI only configuration as following:

```
config system password-policy-guest-admin
   status enable/disable Enable/disable password policy.
   apply-to guest-admin-password Guest admin to which this password policy applies.
   minimum-length  Minimum password length.
   min-lower-case-letter  Minimum number of lowercase characters in password.
   min-upper-case-letter  Minimum number of uppercase characters in password.
   min-non-alphanumeric Minimum number of non-alphanumeric characters in password.
   min-number  Minimum number of numeric characters in password.
   change-4-characters enable/disable Enable/disable changing at least 4 characters for new password.
   expire-status enable/disable Enable/disable password expiration.
   reuse-password enable/disable  Enable/disable reuse of password.
end
```

RADIUS CoA for user, user-group and captive-portal authentication (RFC 5176) (274813 270166)

RADIUS Change of Authorization (CoA) is a common feature in user authentication. User, user-group and captive-portal authentication now supports RADIUS CoA, when the back end authentication server is RADIUS.

The main use case of this feature is with external captive portal, it can be used to disconnect hotspot users when their time, credit or bandwidth had been used up.

- If updating to 5.4.1, see above (309499).

RSSO: Enable or disable overriding old attribute value when a user logs in again (possibly on a different device) (278471)

When receiving a new start message with different group name for the same user and different IP address such as the scenario of a mobile device roaming, the original design is to override all group name information to the latest group name received from the latest start message.

This new feature adds an option to disable this override when needed. The default behavior keeps the original design.

CLI changes

Add an option to enable or disable overriding SSO attribute value.

Syntax

```
config user radius
   edit <My_Rsso>
   set rsso enable
   set sso-attribute-value-override enable/disable // Enable/Disable override old attribute value
       with new value for the same endpoint.
end
```

FSSO supports Microsoft Exchange Server (270174)

FSSO supports monitoring Microsoft Exchange Server. This is useful for situation that the user use the domain account to access their email, but client device might or might not be in the domain. Support for Exchange server is configured on the Back-end FSSO collector agent under **Advanced Settings** > **Exchange Server**.

Select **Add** and enter the following information and select **OK**.

Domain Name	Enter your domain name.
Server IP/Hostname	Enter the IP address or the hostname of your exchange server.
Polling forwarded event log	This option for scenarios when you do not want that CA polls the Exchange Server logs directly. In this case you need to configure event log forwarding on the Exchange server. Exchange event logs can be forwarded to any member server. If you enable this, instead of the IP of the Exchange server configured in the previous step, you must then configure the IP of this member server. CA will then contact the member server.

Ignore Name	Because CA will also check Windows log files for logon events and when a user authenticates to Exchange Server there is also a logon event in Windows event log, which CA will read and this will overwrite the Exchange Server logon event (ES-EventLog) on CA. So it is recommended to set the ignore list to the domain the user belongs to. To do so, enter the domain name in the **Ignore Name** field and select **Add**.

Introduction to authentication

Identifying users and other computers—authentication—is a key part of network security. This section describes some basic elements and concepts of authentication.

The following topics are included in this section:

- What is authentication?
- Methods of authentication
- Types of authentication
- User's view of authentication
- FortiGate administrator's view of authentication

What is authentication?

Businesses need to authenticate people who have access to company resources. In the physical world this may be a swipe card to enter the building, or a code to enter a locked door. If a person has this swipe card or code, they have been authenticated as someone allowed in that building or room.

Authentication is the act of confirming the identity of a person or other entity. In the context of a private computer network, the identities of users or host computers must be established to ensure that only authorized parties can access the network. The FortiGate unit enables controlled network access and applies authentication to users of security policies and VPN clients.

Methods of authentication

FortiGate unit authentication is divided into three basic types: password authentication for people, certificate authentication for hosts or endpoints, and two-factor authentication for additional security beyond just passwords. An exception to this is that FortiGate units in an HA cluster and FortiManager units use password authentication.

Password authentication verifies individual user identities, but access to network resources is based on membership in user groups. For example, a security policy can be configured to permit access only to the members of one or more user groups. Any user who attempts to access the network through that policy is then authenticated through a request for their username and password.

Methods of authentication include:

- Local password authentication
- Server-based password authentication
- Certificate-based authentication
- Two-factor authentication

Local password authentication

The simplest authentication is based on user accounts stored locally on the FortiGate unit. For each account, a username and password is stored. The account also has a disable option so that you can suspend the account without deleting it.

Local user accounts work well for a single-FortiGate installation. If your network has multiple FortiGate units that will use the same accounts, the use of an external authentication server can simplify account configuration and maintenance.

You can create local user accounts in the web-based manager under **User & Device > User > User Definition**. This page is also used to create accounts where an external authentication server stores and verifies the password.

Server-based password authentication

Using external authentication servers is desirable when multiple FortiGate units need to authenticate the same users, or where the FortiGate unit is added to a network that already contains an authentication server. FortiOS supports the use of LDAP, RADIUS, TACACS+, AD or POP3 servers for authentication.

When you use an external authentication server to authenticate users, the FortiGate unit sends the user's entered credentials to the external server. The password is encrypted. The server's response indicates whether the supplied credentials are valid or not.

You must configure the FortiGate unit to access the external authentication servers that you want to use. The configuration includes the parameters that authenticate the FortiGate unit to the authentication server.

You can use external authentication servers in two ways:

- Create user accounts on the FortiGate unit, but instead of storing each user's password, specify the server used to authenticate that user. As with accounts that store the password locally, you add these users to appropriate user groups.
- Add the authentication server to user groups. Any user who has an account on the server can be authenticated and have the access privileges of the FortiGate user group. Optionally, when an LDAP server is a FortiGate user group member, you can limit access to users who belong to specific groups defined on the LDAP server.

Certificate-based authentication

An RSA X.509 server certificate is a small file issued by a Certificate Authority (CA) that is installed on a computer or FortiGate unit to authenticate itself to other devices on the network. When one party on a network presents the certificate as authentication, the other party can validate that the certificate was issued by the CA. The identification is therefore as trustworthy as the Certificate Authority (CA) that issued the certificate.

To protect against compromised or misused certificates, CAs can revoke any certificate by adding it to a Certificate Revocation List (CRL). Certificate status can also be checked online using Online Certificate Status Protocol (OCSP).

RSA X.509 certificates are based on public-key cryptography, in which there are two keys: the private key and the public key. Data encrypted with the private key can be decrypted only with the public key and vice versa. As the names suggest, the private key is never revealed to anyone and the public key can be freely distributed. Encryption with the recipient's public key creates a message that only the intended recipient can read. Encryption with the sender's private key creates a message whose authenticity is proven because it can be decrypted only with the sender's public key.

Server certificates contain a signature string encrypted with the CA's private key. The CA's public key is contained in a CA root certificate. If the signature string can be decrypted with the CA's public key, the certificate is genuine.

Certificate authorities

A certificate authority can be:

- an organization, such as VeriSign Inc., that provides certificate services
- a software application, such as Microsoft Certificate Services or OpenSSH

For a company web portal or customer-facing SSL VPN, a third-party certificate service has some advantages. The CA certificates are already included in popular web browsers and customers trust the third-party. On the other hand, third-party services have a cost.

For administrators and for employee VPN users, the local CA based on a software application provides the required security at low cost. You can generate and distribute certificates as needed. If an employee leaves the organization, you can simply revoke their certificate.

Certificates for users

FortiGate unit administrators and SSL VPN users can install certificates in their web browsers to authenticate themselves. If the FortiGate unit uses a CA-issued certificate to authenticate itself to the clients, the browser will also need the appropriate CA certificate.

FortiGate IPsec VPN users can install server and CA certificates according to the instructions for their IPsec VPN client software. The FortiClient Endpoint Security application, for example, can import and store the certificates required by VPN connections.

FortiGate units are also compatible with some Public Key Infrastructure systems. For an example of this type of system, see RSA ACE (SecurID) servers on page 555.

Two-factor authentication

A user can be required to provide both something they know (their username and password combination) and something they have (certificate or a random token code). Certificates are installed on the user's computer.

Two-factor authentication is available for PKI users. For more information, see Certificate on page 565.

Another type of two-factor authentication is to use a randomly generated token (multi-digit number) along with the username and password combination. One method is a FortiToken — a one time passcode (OTP) generator that generates a unique code every 60 seconds. Others use email or SMS text messaging to deliver the random token code to the user or administrator.

When one of these methods is configured, the user enters this code at login after the username and password have been verified. The FortiGate unit verifies the token code after as well as the password and username. For more information, see Two-factor authentication on page 564

Types of authentication

FortiOS supports two different types of authentication based on your situation and needs.

Security policy authentication is easily applied to all users logging on to a network, or network service. For example if a group of users on your network such as the accounting department who have access to sensitive data need to access the Internet, it is a good idea to make sure the user is a valid user and not someone trying to send company secrets to the Internet. Security policy authentication can be applied to as many or as few users as needed, and it supports a number of authentication protocols to easily fit with your existing network.

Virtual Private Network (VPN) authentication enables secure communication with hosts located outside the company network, making them part of the company network while the VPN tunnel is operating. Authentication applies to the devices at both ends of the VPN and optionally VPN users can be authenticated as well.

Security policy authentication

Security policies enable traffic to flow between networks. Optionally, the policy can allow access only to specific originating addresses, device types, users or user groups. Where access is controlled by user or user group, users must authenticate by entering valid username and password credentials.

The user's authentication expires if the connection is idle for too long, 5 minutes by default but that can be customized.

Security policies are the mechanism for FSSO, NTLM, certificate based, and RADIUS SSO authentication.

FSSO

Fortinet Single Sign on (FSSO) provides seamless authentication support for Microsoft Windows Active Directory (AD) and Novell eDirectory users in a FortiGate environment.

On a Microsoft Windows or Novell network, users authenticate with the Active Directory or Novell eDirectory at logon. FSSO provides authentication information to the FortiGate unit so that users automatically get access to permitted resources. See Introduction to agent-based FSSO on page 646.

NTLM

The NT LAN Manager (NTLM) protocol is used when the MS Windows Active Directory (AD) domain controller can not be contacted. NTLM is a browser-based method of authentication.

The FSSO software is installed on each AD server and the FortiGate unit is configured to communicate with each FSSO client. When a user successfully logs into their Windows PC (and is authenticated by the AD Server), the FSSO client communicates the user's name, IP address, and group login information to the FortiGate unit. The FortiGate unit sets up a temporary access policy for the user, so when they attempt access through the firewall they do not need to re-authenticate. This model works well in environments where the FSSO client can be installed on all AD servers.

In system configurations where it is not possible to install FSSO clients on all AD servers, the FortiGate unit must be able to query the AD servers to find out if a user has been properly authenticated. This is achieved using the NTLM messaging features of Active Directory and Internet Explorer.

Even when NTLM authentication is used, the user is not asked again for their username and password. Internet Explorer stores the user's credentials and the FortiGate unit uses NTLM messaging to validate them in the Windows AD environment.

Note that if the authentication reaches the timeout period, the NTLM message exchange restarts. For more information on NTLM, see NTLM authentication on page 595 and FSSO NTLM authentication support on page 652.

Certificates

Certificates can be used as part of a policy. All users being authenticated against the policy are required to have the proper certificate. See Certificate-based authentication on page 614

RADIUS SSO

RADIUS Single Sign-On (RSSO) is a remote authentication method that does not require any local users to be configured, and relies on RADIUS Start records to provide the FortiGate unit with authentication information. That information identifies the user and user group, which is then matched using a security policy. See SSO using RADIUS accounting records on page 691.

FortiGuard Web Filter override authentication

Optionally, users can be allowed the privilege of overriding FortiGuard Web Filtering to view blocked web sites. Depending on the override settings, the override can apply to the user who requested it, the entire user group to which the user belongs, or all users who share the same web filter profile. As with other FortiGate features, access to FortiGuard overrides is controlled through user groups. Firewall and Directory Services user groups are eligible for the override privilege. For more information about web filtering and overrides, see the UTM chapter of this FortiOS Handbook.

VPN authentication

Authentication involves authenticating the user. In IPsec VPNs authenticating the user is optional, but authentication of the peer device is required.

This section includes:

- Authenticating IPsec VPN peers (devices)
- Authenticating IPsec VPN users
- Authenticating SSL VPN users
- Authenticating PPTP and L2TP VPN users

Authenticating IPsec VPN peers (devices)

A VPN tunnel has one end on a local trusted network, and the other end is at a remote location. The remote peer (device) must be authenticated to be able to trust the VPN tunnel. Without that authentication, it is possible for a malicious hacker to masquerade as a valid VPN tunnel device and gain access to the trusted local network.

The three ways to authenticate VPN peers are with a preshared key, RSA X.509 certificate, or a specific peer ID value.

The simplest way for IPsec VPN peers to authenticate each other is through the use of a preshared key, also called a shared secret. The preshared key is a text string used to encrypt the data exchanges that establish the VPN tunnel. The preshared key must be six or more characters. The VPN tunnel cannot be established if the two peers do not use the same key. The disadvantage of preshared key authentication is that it can be difficult to securely distribute and update the preshared keys.

RSA X.509 certificates are a better way for VPN peers to authenticate each other. Each peer offers a certificate signed by a Certificate Authority (CA) which the other peer can validate with the appropriate CA root certificate. For more information about certificates, see Certificate-based authentication on page 614.

You can supplement either preshared key or certificate authentication by requiring the other peer to provide a specific peer ID value. The peer ID is a text string configured on the peer device. On a FortiGate peer or FortiClient Endpoint Security peer, the peer ID provided to the remote peer is called the Local ID.

Authenticating IPsec VPN users

An IPsec VPN can be configured to accept connections from multiple dynamically addressed peers. You would do this to enable employees to connect to the corporate network while traveling or from home. On a FortiGate unit, you create this configuration by setting the **Remote Gateway** to **Dialup User**.

It is possible to have an IPsec VPN in which remote peer devices authenticate using a common preshared key or a certificate, but there is no attempt to identify the user at the remote peer. To add user authentication, you can do one of the following:

- require a unique preshared key for each peer
- require a unique peer ID for each peer
- require a unique peer certificate for each peer
- require additional user authentication (XAuth)

The peer ID is a text string configured on the peer device. On a FortiGate peer or FortiClient Endpoint Security peer, the peer ID provided to the remote peer is called the Local ID.

Authenticating SSL VPN users

SSL VPN users can be

- user accounts with passwords stored on the FortiGate unit
- user accounts authenticated by an external RADIUS, LDAP or TACACS+ server
- PKI users authenticated by certificate

You need to create a user group for your SSL VPN. Simply create a firewall user group, enable SSL VPN access for the group, and select the web portal the users will access.

SSL VPN access requires an SSL VPN security policy that permits access to members of your user group.

Authenticating PPTP and L2TP VPN users

PPTP and L2TP are older VPN tunneling protocols that do not provide authentication themselves. FortiGate units restrict PPTP and L2TP access to users who belong to one specified user group. Users authenticate themselves to the FortiGate unit by username/password. You can configure PPTP and L2TP VPNs only in the CLI. Before you configure the VPN, create a firewall user group and add to it the users who are permitted to use the VPN. Users are authenticated when they attempt to connect to the VPN. For more information about configuring PPTP or L2TP VPNs, see the FortiGate CLI Reference.

Single Sign-On authentication for users

“Single Sign-On” means that users logged on to a computer network are authenticated for access to network resources through the FortiGate unit without having to enter their username and password again. FortiGate units directly provide Single Sign On capability for:

- Microsoft Windows networks using either Active Directory or NTLM authentication
- Novell networks, using eDirectory

In combination with a FortiAuthenticator unit, the FortiGate unit can provide Single Sign-On capability that integrates multiple external network authentication systems such as Windows Active Directory, Novell e-Directory, RADIUS and LDAP. The FortiAuthenticator unit gathers user logon information from all of these sources and sends it to the FortiGate unit.

Through the SSO feature, the FortiGate unit knows the username, IP address, and external user groups to which the user belongs. When the user tries to access network resources, the FortiGate unit selects the appropriate security policy for the destination. If the user belongs to one of the permitted user groups, the connection is allowed.

For detailed information about SSO, see

- Single Sign-On using a FortiAuthenticator unit on page 634
- Agent-based FSSO on page 646

User's view of authentication

From the user's point of view, they see a request for authentication when they try to access a protected resource, such as an FTP repository of intellectual property or simply access a website on the Internet. The way the request is presented to the user depends on the method of access to that resource.

VPN authentication usually controls remote access to a private network.

Web-based user authentication

Security policies usually control browsing access to an external network that provides connection to the Internet. In this case, the FortiGate unit requests authentication through the web browser.

The user types a username and password and then selects **Continue** or **Login**. If the credentials are incorrect, the authentication screen is redisplayed with blank fields so that the user can try again. When the user enters valid credentials, access is granted to the required resource. In some cases, if a user tries to authenticate several times without success, a message appears, such as: "Too many bad login attempts. Please try again in a few minutes." This indicates the user is locked out for a period of time. This prevents automated brute force password hacking attempts. The administrator can customize these settings if required.

After a defined period of user inactivity (the authentication timeout, defined by the FortiGate administrator), the user's access expires. The default is 5 minutes. To access the resource, the user will have to authenticate again.

VPN client-based authentication

A VPN provides remote clients with access to a private network for a variety of services that include web browsing, email, and file sharing. A client program such as FortiClient negotiates the connection to the VPN and manages the user authentication challenge from the FortiGate unit.

FortiClient can store the username and password for a VPN as part of the configuration for the VPN connection and pass them to the FortiGate unit as needed. Or, FortiClient can request the username and password from the user when the FortiGate unit requests them.

SSL VPN is a form of VPN that can be used with a standard Web browser. There are two modes of SSL VPN operation (supported in NAT/Route mode only):

- web-only mode, for remote clients equipped with a web-browser only
- tunnel mode, for remote computers that run a variety of client and server applications.

After a defined period of user inactivity on the VPN connection (the idle timeout, defined by the FortiGate administrator), the user's access expires. The default is 30 minutes. To access the resource, the user will have to authenticate again.

FortiGate administrator's view of authentication

Authentication is based on user groups. The FortiGate administrator configures authentication for security policies and VPN tunnels by specifying the user groups whose members can use the resource. Some planning is required to determine how many different user groups need to be created. Individual user accounts can belong to multiple groups, making allocation of user privileges very flexible.

A member of a user group can be:

- a user whose username and password are stored on the FortiGate unit
- a user whose name is stored on the FortiGate unit and whose password is stored on a remote or external authentication server
- a remote or external authentication server with a database that contains the username and password of each person who is permitted access

The general process of setting up authentication is as follows:

1. If remote or external authentication is needed, configure the required servers.
2. Configure local and peer (PKI) user identities. For each local user, you can choose whether the FortiGate unit or a remote authentication server verifies the password. Peer members can be included in user groups for use in security policies.
3. Create user groups.
4. Add local/peer user members to each user group as appropriate. You can also add an authentication server to a user group. In this case, all users in the server's database can authenticate. You can only configure peer user groups through the CLI.
5. Configure security policies and VPN tunnels that require authenticated access.

For authentication troubleshooting, see the specific chapter for the topic or for general issues see Troubleshooting on page 716.

General authentication settings

Go to **User & Device > Authentication > Settings** to configure authentication timeout, protocol support, and authentication certificates.

When user authentication is enabled within a security policy, the authentication challenge is normally issued for any of the four protocols (depending on the connection protocol):

- HTTP (can also be set to redirect to HTTPS)
- HTTPS
- FTP
- Telnet

The selections made in the **Protocol Support** list of **Authentication Settings** control which protocols support the authentication challenge. Users must connect with a supported protocol first so they can subsequently connect with other protocols. If HTTPS is selected as a method of protocol support, it allows the user to authenticate with a customized Local certificate.

When you enable user authentication within a security policy, the security policy user will be challenged to authenticate. For user ID and password authentication, users must provide their user names and passwords. For certificate authentication (HTTPS or HTTP redirected to HTTPS only), you can install customized certificates on the unit and the users can also have customized certificates installed on their browsers. Otherwise, users will see a warning message and have to accept a default Fortinet certificate.

Authentication Timeout	Enter a length of time in minutes, from 1 to 1440 (24 hours). Authentication timeout controls how long an authenticated firewall connection can be idle before the user must authenticate again. The default value is 5.

Protocol Support	Select the protocols to challenge during firewall user authentication.
Certificate	If using HTTPS protocol support, select the local certificate to use for authentication. Available only if HTTPS protocol support is selected.
Apply	Select to apply the selections for user authentication settings.

Authentication servers

FortiGate units support the use of external authentication servers. An authentication server can provide password checking for selected FortiGate users or it can be added as a member of a FortiGate user group.

If you are going to use authentication servers, you must configure the servers before you configure FortiGate users or user groups that require them.

Mac OS and iOS devices, including iPhones and iPads, can perform user authentication with FortiOS units using RADIUS servers, but not with LDAP or TACACS+ servers.

This section includes the following topics:

- FortiAuthenticator servers
- RADIUS servers
- LDAP servers
- TACACS+ servers
- POP3 servers
- SSO servers
- RSA ACE (SecurID) servers

FortiAuthenticator servers

FortiAuthenticator is an Authentication, Authorization, and Accounting (AAA) server, that includes a RADIUS server, an LDAP server, and can replace the FSSO Collector Agent on a Windows AD network. Multiple FortiGate units can use a single FortiAuthenticator for FSSO, remote authentication, and FortiToken management.

For more information, see the FortiAuthenticator Administration Guide.

RADIUS servers

Remote Authentication and Dial-in User Service (RADIUS) is a broadly supported client-server protocol that provides centralized authentication, authorization, and accounting functions. RADIUS clients are built into gateways that allow access to networks such as Virtual Private Network servers, Network Access Servers (NAS), as well as network switches and firewalls that use authentication. FortiGate units fall into the last category.

RADIUS servers use UDP packets to communicate with the RADIUS clients on the network to authenticate users before allowing them access to the network, to authorize access to resources by appropriate users, and to account or bill for those resources that are used. RADIUS servers are currently defined by RFC 2865 (RADIUS) and RFC 2866 (Accounting), and listen on either UDP ports 1812 (authentication) and 1813 (accounting) or ports 1645 (authentication) and 1646 (accounting) requests. RADIUS servers exist for all major operating systems.

You must configure the RADIUS server to accept the FortiGate unit as a client. FortiGate units use the authentication and accounting functions of the RADIUS server.

FortiOS does not accept all characters from auto generated keys from MS Windows 2008. These keys are very long and as a result RADIUS authentication will not work. Maximum key length for MS Windows 2008 is 128 bytes. In older versions of FSAE, it was 40 bytes.

Microsoft RADIUS servers

Microsoft Windows Server 2000, 2003, and 2008 have RADIUS support built-in. Microsoft specific RADIUS features are defined in RFC 2548. The Microsoft RADIUS implementation can use Active Directory for user credentials.

For details on Microsoft RADIUS server configurations, refer to Microsoft documentation.

RADIUS user database

The RADIUS user database is commonly an SQL or LDAP database, but can also be any combination of:

- usernames and passwords defined in a configuration file
- user account names and passwords configured on the computer where the RADIUS server is installed.

If users are members of multiple RADIUS groups, then the user group authentication timeout value does not apply. See Membership in multiple groups on page 577.

RADIUS authentication with a FortiGate unit

To use RADIUS authentication with a FortiGate unit

- configure one or more RADIUS servers on the FortiGate unit
- assign users to a RADIUS server

When a configured user attempts to access the network, the FortiGate unit will forward the authentication request to the RADIUS server which will match the username and password remotely. Once authenticated the RADIUS server passes the authorization granted message to the FortiGate unit which grants the user permission to access the network.

The RADIUS server uses a “shared secret” key along with MD5 hashing to encrypt information passed between RADIUS servers and clients, including the FortiGate unit. Typically only user credentials are encrypted. Additional security can be configured through IPsec tunnels by placing the RADIUS server behind another VPN gateway.

RADIUS attribute value pairs

RADIUS packets include a set of attribute value pairs (AVP) to identify information about the user, their location and other information. The FortiGate unit sends the following RADIUS attributes.

FortiOS supported RADIUS attributes

RADIUS Attribute	Name	Description	AVP type
1	Acct-Session-ID	Unique number assigned to each start and stop record to make it easy to match them, and to eliminate duplicate records.	44

RADIUS Attribute	Name	Description	AVP type
2	Username	Name of the user being authenticated	1
3	NAS-Identifier	Identifier or IP address of the Network Access Server (NAS) that is requesting authentication. In this case, the NAS is the FortiGate unit.	32
4	Framed-IP-Address	Address to be configured for the user.	8
5	Fortinet-VSA	See Vendor-specific attributes on page 540	26
6	Acct-Input-Octets	Number of octets received from the port over the course of this service being provided. Used to charge the user for the amount of traffic they used.	42
7	Acct-Output-Octets	Number of octets sent to the port while delivering this service. Used to charge the user for the amount of traffic they used.	43

The following table describes the supported authentication events and the RADIUS attributes that are sent in the RADIUS accounting message.

RADIUS attributes sent in RADIUS accounting message

	RADIUS Attributes						
Authentication Method	**1**	**2**	**3**	**4**	**5**	**6**	**7**
Web	X	X	X		X		
XAuth of IPsec (without DHCP)	X	X	X		X		
XAuth of IPsec (with DHCP)	X	X	X	X	X		
PPTP/L2TP (in PPP)	X	X	X	X	X	X	X
SSL-VPN	X	X	X	X	X		

External captive portal POST message

In external RADIUS captive portal, the captive portal web page is a script that gathers the user's logon credentials and sends it back to the FortiGate as a POST message. Session URL parameters are sent from the client in a POST messages, and in the redirect. These parameters are separated by **&** characters (see examples below):

POST message to redirect server:

```
http://<redirectserver>/index2.php/?login&post=http://192.168.200.1:1000/fgtau
th&magic=02050f889bc21644&usermac=54:26:96:16:a2:45&apmac=00:09:0f:b9:f4:c0&ap
ip=127.0.0.1&userip=192.168.200.2
```

POST message back to the FortiGate:

```
http://FGT_IP_addr:1000/fgtauth
```

The magic text data, provided in the initial FortiGate request to the web server, contains the username, password paramaters:

```
magic=00050c839182f095&username=<username>&password=<password>
```

Vendor-specific attributes

Vendor specific attributes (VSA) are the method RADIUS servers and client companies use to extend the basic functionality of RADIUS. Some major vendors, such as Microsoft, have published their VSAs, however many do not.

In order to support vendor-specific attributes (VSA), the RADIUS server requires a dictionary to define which VSAs to support. This dictionary is typically supplied by the client or server vendor.

The Fortinet RADIUS vendor ID is 12356.

The FortiGate unit RADIUS VSA dictionary is supplied by Fortinet and is available through the Fortinet Knowledge Base (http://kb.forticare.com) or through Technical Support. Fortinet's dictionary for FortiOS 4.0 and up is configured this way:

```
##
Fortinet's VSA's
#
VENDOR fortinet 12356
BEGIN-VENDOR fortinet
ATTRIBUTE Fortinet-Group-Name   1   string
ATTRIBUTE Fortinet-Client-IP-Address   2   ipaddr
ATTRIBUTE Fortinet-Vdom-Name   3   string
ATTRIBUTE Fortinet-Client-IPv6-Address   4   octets
ATTRIBUTE Fortinet-Interface-Name   5   string
ATTRIBUTE Fortinet-Access-Profile   6   string
#
# Integer Translations
#
END-VENDOR Fortinet
```

Note that using the Fortinet-Vdom-Name, users can be tied to a specific VDOM on the FortiGate unit. See the documentation provided with your RADIUS server for configuration details.

Role Based Access Control

In Role Based Access Control (RBAC), network administrators and users have varying levels of access to network resources based on their role, and that role's requirement for access specific resources. For example, a junior accountant does not require access to the sales presentations, or network user account information.

There are three main parts to RBAC: role assignment, role authorization, and transaction authorization. Role assignment is accomplished when someone in an organization is assigned a specific role by a manager or HR. Role authorization is accomplished when a network administrator creates that user's RADIUS account and assigns them to the required groups for that role. Transaction authorization occurs when that user logs on and authenticates before performing a task.

RBAC is enforced when FortiOS network users are remotely authenticated via a RADIUS server. For users to authenticate, a security policy must be matched. That policy only matches a specific group of users. If VDOMs are enabled, the matched group will be limited to a specific VDOM. Using this method network administrators can separate users into groups that match resources, protocols, or VDOMs. It is even possible to limit users to specific FortiGate units if the RADIUS servers serve multiple FortiOS units.

For more information on security policies, see Authentication in security policies on page 589.

Configuring the FortiGate unit to use a RADIUS server

The information you need to configure the FortiGate unit to use a RADIUS server includes

- the RADIUS server's domain name or IP address
- the RADIUS server's shared secret key.

You can optionally specify the NAS IP or Called Station ID. When configuring the FortiGate to use a RADIUS server, the FortiGate is a Network Access Server (NAS). If the FortiGate interface has multiple IP addresses, or you want the RADIUS requests to come from a different address you can specify it here. Called Station ID applies to carrier networks. However, if the NAS IP is not included in the RADIUS configuration, the IP of the FortiGate unit interface that communicates with the RADIUS server is used instead.

A maximum of 10 remote RADIUS servers can be configured on the FortiGate unit. One or more servers must be configured on FortiGate before remote users can be configured. To configure remote users, see Local and remote users on page 561.

On the FortiGate unit, the default port for RADIUS traffic is 1812. Some RADIUS servers use port 1645. If this is the case with your server, you can either:

- Re-configure the RADIUS server to use port 1812. See your RADIUS server documentation for more information on this procedure.

or

- Change the FortiGate unit default RADIUS port to 1645 using the CLI:

```
config system global
   set radius-port 1645
end
```

One wildcard admin account can be added to the FortiGate unit when using RADIUS authentication. This uses the wildcard character to allow multiple admin accounts on RADIUS to use a single account on the FortiGate unit. See Example — wildcard admin accounts - CLI on page 548.

To configure the FortiGate unit for RADIUS authentication - web-based manager:

1. Go to **User & Device > Authentication > RADIUS Servers** and select **Create New**.
2. Enter the following information and select **OK**.

Name	A name to identify the RADIUS server on the FortiGate unit.
Primary Server Name/IP	Enter the domain name (such as fgt.exmaple.com) or the IP address of the RADIUS server.
Primary Server Secret	Enter the server secret key, such as radiusSecret. This can be a maximum of 16 characters long. This must match the secret on the RADIUS primary server.
Secondary Server Name/IP	Optionally enter the domain name (such as fgt.exmaple.com) or the IP address of the secondary RADIUS server.
Secondary Server Secret	Optionally, enter the secondary server secret key, such as radiusSecret2. This can be a maximum of 16 characters long. This must match the secret on the RADIUS secondary server.
Authentication Scheme	If you know the RADIUS server uses a specific authentication protocol, select it from the list. Otherwise select **Use Default Authentication Scheme**. The Default option will usually work.
NAS IP/ Called Station ID	Enter the IP address to be used as an attribute in RADIUS access requests. **NAS-IP-Address** is RADIUS setting or IP address of FortiGate interface used to talk to RADIUS server, if not configured. **Called Station ID** is same value as NAS-IP Address but in text format.
Include in every User Group	When enabled this RADIUS server will automatically be included in all user groups. This is useful if all users will be authenticating with the remote RADIUS server.

For MAC OS and iOS devices to authenticate, you must use MS-CHAP-v2 authentication. In the CLI, the command is `set auth-type ms_chap_v2`.

3. Select **OK**.

To configure the FortiGate unit for RADIUS authentication - CLI example:

```
config user radius
   edit ourRADIUS
      set auth-type auto
      set server 10.11.102.100
      set secret radiusSecret
   end
```

For more information about RADIUS server options, refer to the FortiGate CLI Reference.

Troubleshooting RADIUS

To test the connection to the RADIUS server use the following command:

```
diagnose test authserver radius-direct <server_name or IP> <port number> <secret>
```

For the port number, enter `-1` to use the default port. Otherwise enter the port number to check.

LDAP servers

Lightweight Directory Access Protocol (LDAP) is an Internet protocol used to maintain authentication data that may include departments, people, groups of people, passwords, email addresses, and printers. LDAP consists of a data-representation scheme, a set of defined operations, and a request/response network.

The scale of LDAP servers range from big public servers such as BigFoot and Infospace, to large organizational servers at universities and corporations, to small LDAP servers for workgroups that may be using OpenLDAP. This document focuses on the institutional and workgroup applications of LDAP.

This section includes:

- Components and topology
- LDAP directory organization
- Configuring the FortiGate unit to use an LDAP server
- Example — wildcard admin accounts - CLI
- Example of LDAP to allow Dial-in through member-attribute - CLI
- Troubleshooting LDAP

Components and topology

LDAP organization starts with directories. A directory is a set of objects with similar attributes organized in a logical and hierarchical way. Generally, an LDAP directory tree reflects geographic and organizational boundaries, with the Domain name system (DNS) names to structure the top level of the hierarchy. The common name identifier for most LDAP servers is `cn`, however some servers use other common name identifiers such as `uid`.

When LDAP is configured and a user is required to authenticate the general steps are:

1. The FortiGate unit contacts the LDAP server for authentication.
2. To authenticate with the FortiGate unit, the user enters a username and password.
3. The FortiGate unit sends this username and password to the LDAP server.
4. If the LDAP server can authenticate the user, the user is successfully authenticated with the FortiGate unit.
5. If the LDAP server cannot authenticate the user, the connection is refused by the FortiGate unit.

Binding

Binding is the step where the LDAP server authenticates the user. If the user is successfully authenticated, binding allows the user access to the LDAP server based on that user's permissions.

The FortiGate unit can be configured to use one of three types of binding:

- anonymous - bind using anonymous user search
- regular - bind using username/password and then search
- simple - bind using a simple password authentication without a search

You can use simple authentication if the user records all fall under one domain name (`dn`). If the users are under more than one `dn`, use the anonymous or regular type, which can search the entire LDAP database for the required username.

If your LDAP server requires authentication to perform searches, use the regular type and provide values for username and password.

Supported versions

The FortiGate unit supports LDAP protocol functionality defined in RFC 2251: Lightweight Directory Access Protocol v3, for looking up and validating user names and passwords. FortiGate LDAP supports all LDAP servers compliant with LDAP v3, including FortiAuthenticator. In addition, FortiGate LDAP supports LDAP over SSL/TLS, which can be configured only in the CLI.

FortiGate LDAP does not support proprietary functionality, such as notification of password expiration, which is available from some LDAP servers. FortiGate LDAP does not supply information to the user about why authentication failed.

LDAP user authentication is supported for PPTP, L2TP, IPsec VPN, and firewall authentication.

However, with PPTP, L2TP, and IPsec VPN, PAP (Packet Authentication Protocol) is supported, while CHAP (Challenge Handshake Authentication Protocol) is not.

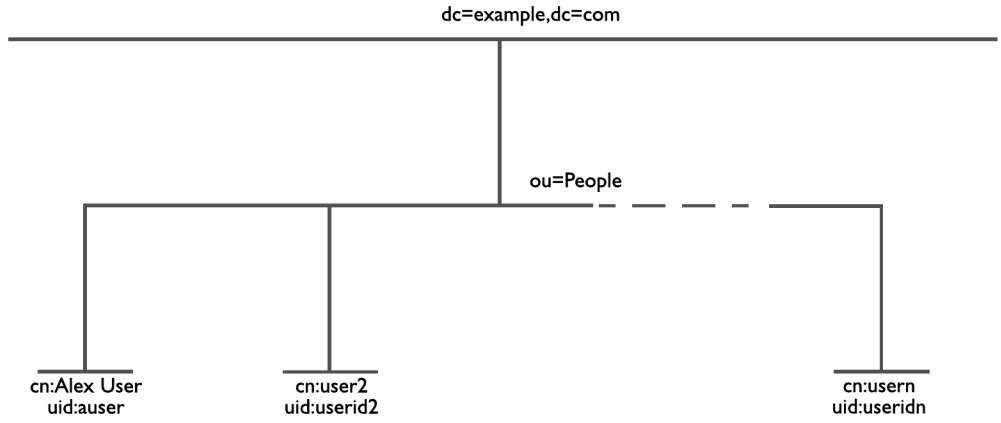
LDAP directory organization

To configure your FortiGate unit to work with an LDAP server, you need to understand the organization of the information on the server.

The top of the hierarchy is the organization itself. Usually this is defined as Domain Component (DC), a DNS domain. If the name contains a dot, such as `example.com`, it is written as two parts separated by a comma: `dc=example,dc=com`.

In this example, Common Name (CN) identifiers reside at the Organization Unit (OU) level, just below DC. The Distinguished Name (DN) is ou=People,dc=example,dc=com.

LDAP object hierarchy



In addition to the DN, the FortiGate unit needs an identifier for the individual person. Although the FortiGate unit GUI calls this the Common Name (CN), the identifier you use is not necessarily CN. On some servers, CN is the full name of a person. It might be more convenient to use the same identifier used on the local computer network. In this example, User ID (UID) is used.

Locating your identifier in the hierarchy

You need to determine the levels of the hierarchy from the top to the level that contain the identifier you want to use. This defines the DN that the FortiGate unit uses to search the LDAP database. Frequently used distinguished name elements include:

- uid (user identification)
- pw (password)
- cn (common name)
- ou (organizational unit)
- o (organization)
- c (country)

One way to test this is with a text-based LDAP client program. For example, OpenLDAP includes a client, `ldapsearch`, that you can use for this purpose.

Enter the following at the command line:

```
ldapsearch -x '(objectclass=*)'
```

The output is lengthy, but the information you need is in the first few lines:

```
version: 2
#
# filter: (objectclass=*)
# requesting: ALL

dn: dc=example,dc=com
dc: example
objectClass: top
objectClass: domain

dn: ou=People,dc=example,dc=com
ou: People
objectClass: top
objectClass: organizationalUnit
...
dn: uid=tbrown,ou=People,dc=example,dc=com
uid: tbrown
cn: Tom Brown
```

In the output above, you can see `tbrown` (uid) and `Tom Brown`(cn). Also note the dn is `ou=People, dc=example, dc=com`.

Configuring the FortiGate unit to use an LDAP server

After you determine the common name and distinguished name identifiers and the domain name or IP address of the LDAP server, you can configure the server on the FortiGate unit. The maximum number of remote LDAP servers that can be configured is 10.

One or more servers must be configured on FortiGate before remote users can be configured. To configure remote users, see Local and remote users on page 561.

To configure the FortiGate unit for LDAP authentication - web-based manager:

1. Go to **User & Device > Authentication > LDAP Servers** and select **Create New**.
2. Enter a **Name** for the LDAP server.
3. In **Server Name/IP** enter the server's FQDN or IP address.
4. If necessary, change the **Server Port** number. The default is port 389.
5. Enter the **Common Name Identifier** (20 characters maximum).
   `cn` is the default, and is used by most LDAP servers.
6. In the **Distinguished Name** field, enter the base distinguished name for the server using the correct X.500 or LDAP format.
   The FortiGate unit passes this distinguished name unchanged to the server. The maximum number of characters is 512.
   If you don't know the distinguished name, leave the field blank and select the Query icon to the right of the field. See Using the Query icon on page 547.
7. In the **Distinguished Name** field, enter the base distinguished name for the server using the correct X.500 or LDAP format.
   The FortiGate unit passes this distinguished name unchanged to the server. The maximum number of characters is 512.
   If you don't know the distinguished name, leave the field blank and select the Query icon to the right of the field. See Using the Query icon on page 547.
8. In **Bind Type**, select **Regular**.
9. In **User DN**, enter the LDAP administrator's distinguished name.
10. In **Password**, enter the LDAP administrator's password.
11. Select **OK**.

To verify your Distinguished Name field is correct, you can select the **Test** button. If your DN field entry is valid, you will see the part of the LDAP database it defines. If your DN field entry is not valid, it will display an error message and return no information.

For detailed information about configuration options for LDAP servers, see the Online Help on your FortiGate unit or the FortiGate CLI Reference.

To configure the FortiGate unit for LDAP authentication - CLI example:

```
config user ldap
   edit ourLDAPsrv
      set server 10.11.101.160
      set cnid cn
      set dn cn=users,dc=office,dc=example,dc=com
      set type regular
      set username cn=administrator,cn=users,dc=office,dc=example,dc=com
      set password w5AiGVMLkgyPQ
      set password-expiry-warning enable
      set password-renewal enable
   end
```

password-expiry-warning and password-renewal

In SSLVPN, when an LDAP user is connecting to the LDAP server it is possible for them to receive any pending password expiry or renewal warnings. When the password renewal or expiry warning exists, SSLVPN users will see a prompt allowing them to change their password.

`password-expiry-warning` allows FortiOS to detect from the LDAP server when a password is expiring or has expired using server controls or error codes.

`password-renewal` allows FortiOS to perform the online LDAP password renewal operations the LDAP server expects.

On an OpenLDAP server, when a user attempts to logon with an expired password they are allowed to logon but only to change their password.

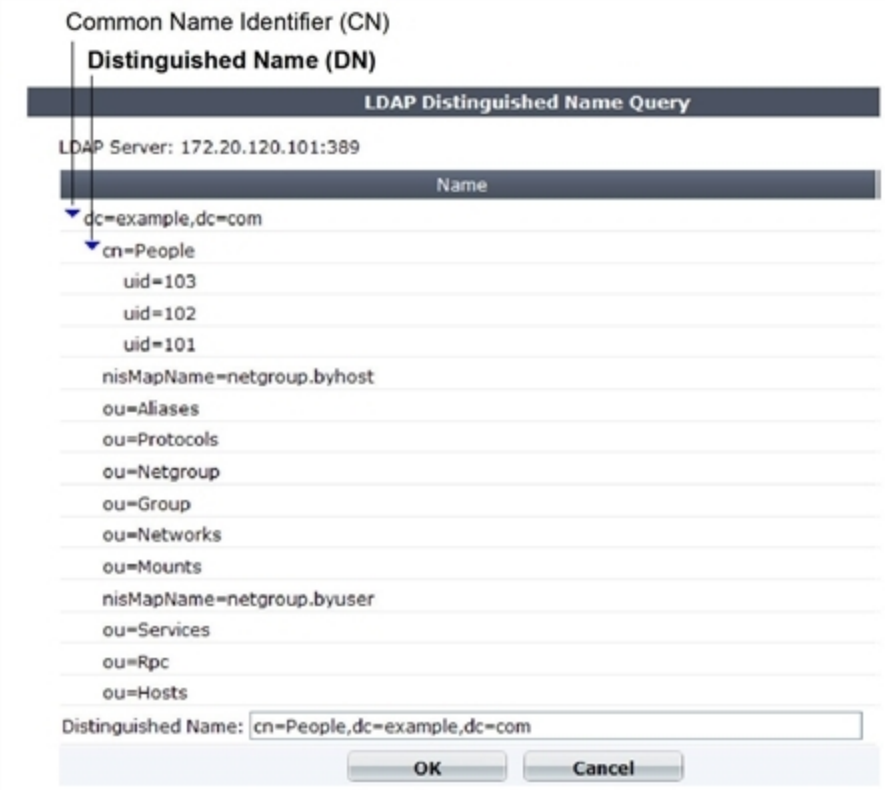
When changing passwords on a Windows AD system, the connection must be SSL-protected.

Using the Query icon

The LDAP Distinguished Name Query list displays the LDAP directory tree for the LDAP server connected to the FortiGate unit. This helps you to determine the appropriate entry for the DN field. To see the distinguished name associated with the Common Name identifier, select the Expand icon next to the CN identifier. Select the DN from the list. The DN you select is displayed in the Distinguished Name field. Select OK and the Distinguished Name you selected will be saved in the Distinguished Name field of the LDAP Server configuration.

To see the users within the LDAP Server user group for the selected Distinguished Name, expand the Distinguished Name in the LDAP Distinguished Name Query tree.

LDAP server Distinguished Name Query tree



Example — wildcard admin accounts - CLI

A wildcard admin account is an administrator account with the wildcard option enabled. This option allows multiple different remote administration accounts to match one local administration account, avoiding the need to set up individual admin accounts on the FortiGate unit. Instead multiple LDAP admin accounts will all be able to use one FortiGate admin account.

The initial benefit of wildcard admin accounts is fast configuration of the FortiGate unit's administration account to work with your LDAP network. The many to one ratio saves on effort, and potential errors.

The ongoing benefit is that as long as the users on the LDAP system belong to that group, and the test admin user settings don't change on the FortiGate unit, no other work is required. This point is important as it can help avoid system updates or changes that would otherwise require changes to the LDAP administrator account configuration. Even if a user is added to or removed from the LDAP group, no changes are required on the FortiGate unit.

Two potential issues with wildcard admin accounts are that multiple users may be logged on to the same account at the same time. This becomes an issue if they are changing the same information at the same time. The other potential issue is that security is reduced because multiple people have login access for the same account. If each user was assigned their own account, a hijacking of one account would not affect the other users.

Note that wildcard admin configuration also applies to RADIUS. When configuring for RADIUS, configure the RADIUS server, and RADIUS user group instead of LDAP. When using web-based management, wildcard admin is the only type of remote administrator account that does not require you to enter a password on account creation. That password is normally used when the remote authentication server is unavailable during authentication.

In this example, default values are used where possible. If a specific value is not mentioned, it is set to its default value.

Configuring the LDAP server

The important parts of this configuration are the username and group lines. The username is the domain administrator account. The group binding allows only the group with the name `GRP` to access.

The `dn` used here is as an example only. On your network use your own domain name.

To configure LDAP server - CLI:

```
config user ldap
   edit "ldap_server"
      set server "192.168.201.3"
      set cnid "sAMAccountName"
      set dn "DC=example,DC=com,DC=au"
      set type regular
      set username "CN=Administrator,CN=Users,DC=example,DC=COM"
      set password *
      set group-member-check group-object
      set group-object-filter (&
          (objectcategory=group)member="CN=GRP,OU=training,DC=example,DC=COM"))
   next
end
```

To configure the user group and add the LDAP server - CLI:

```
config user group
   edit "ldap_grp"
      set member "ldap"
         config match
            edit 1
               set server-name "ldap_server"
               set group-name "CN=GRP,OU=training,DC=example,DC=COM"
            next
         end
      next
   end
```

Configuring the admin account

The wildcard part of this example is only available in the CLI for admin configuration. When enabled, this allows all LDAP group members to login to the FortiGate unit without the need to create a separate admin account for each user. In effect the members of that group will each be able to login as “test”.

To configure the admin account - CLI:

```
config system admin
   edit "test"
      set remote-auth enable
      set accprofile "super_admin"
      set wildcard enable
      set remote-group "ldap_grp"
   next
end
```

For troubleshooting, test that the admin account is operational, and see Troubleshooting LDAP on page 550.

Example of LDAP to allow Dial-in through member-attribute - CLI

In this example, users defined in MicroSoft Windows Active Directory (AD) are allowed to setup a VPN connection simply based on an attribute that is set to TRUE, instead of based on being part of a specific group.

In AD, the “Allow Dial-In” property is activated in the user properties, and this sets the `msNPAllowDialin` attribute to “TRUE”.

This same procedure can be used for other member attributes, as your system requires.

Configuring LDAP member-attribute settings

To accomplish this with a FortiGate unit, the member attribute must be set. Setting member attributes can only be accomplished through the CLI using the `member-attr` keyword - the option is not available through the web-based manager.

Before configuring the FortiGate unit, the AD server must be configured and have the `msNPAllowDialin` attribute set to “TRUE” for the users in question. If not, those users will not be able to properly authenticate.

The dn used here is as an example only. On your network use your own domain name.

To configure user LDAP member-attribute settings - CLI:

```
config user ldap
```

```
    edit "ldap_server"
      set server "192.168.201.3"
      set cnid "sAMAccountName"
      set dn "DC=fortinet,DC=com,DC=au"
      set type regular
      set username "fortigate@example.com"
      set password ******
      set member-attr "msNPAllowDialin"
    next
end
```

Configuring LDAP group settings

A user group that will use LDAP must be configured. This example adds the member `ldap` to the group which is the LDAP server name that was configured earlier.

To configure LDAP group settings - CLI:

```
config user group
   edit "ldap_grp"
      set member "ldap"
      config match
      edit 1
         set server-name "ldap"
         set group-name "TRUE"
      next
   end
end
```

Once these settings are in place, users can authenticate.

Troubleshooting LDAP

The examples in this section use the values from the previous example.

LDAP user test

A quick way to see if the LDAP configuration is correct is to run a diagnose CLI command with LDAP user information. The following command tests with a user called `netAdmin` and a password of `fortinet`. If the configuration is correct the test will be successful.

```
FGT# diag test authserver ldap ldap_server netAdmin fortinet
```

`'ldap_server' is not a valid ldap server name` — an LDAP server by that name has not been configured on the FortiGate unit, check your spelling.

`authenticate 'netAdmin' against 'ldap_server' failed!` — the user `netAdmin` does not exist on `ldap_server`, check your spelling of both the user and sever and ensure the user has been configured on the FortiGate unit.

LDAP authentication debugging

For a more in-depth test, you can use a `diag debug` command. The sample output from a shows more information about the authentication process that may prove useful if there are any problems.

Ensure the “Allow Dial-in” attribute is still set to “TRUE” and run the following CLI command. `fnbamd` is the Fortinet non-blocking authentication daemon.

```
FGT# diag debug enable
FGT# diag debug reset
FGT# diag debug application fnbamd -1
FGT# diag debug enable
```

The output will look similar to:

```
get_member_of_groups-Get the memberOf groups.
get_member_of_groups- attr='msNPAllowDialin', found 1 values
get_member_of_groups-val[0]='TRUE'
fnbamd_ldap_get_result-Auth accepted
fnbamd_ldap_get_result-Going to DONE state res=0
fnbamd_auth_poll_ldap-Result for ldap svr 192.168.201.3 is SUCCESS
fnbamd_auth_poll_ldap-Passed group matching
```

If the “Allow Dial-in” attribute is not set but it is expected, the last line of the above output will instead be:

```
fnbamd_auth_poll_ldap-Failed group matching
```

TACACS+ servers

When users connect to their corporate network remotely, they do so through a remote access server. As remote access technology has evolved, the need for security when accessing networks has become increasingly important. This need can be filled using a Terminal Access Controller Access-Control System (TACACS+) server.

TACACS+ is a remote authentication protocol that provides access control for routers, network access servers, and other networked computing devices via one or more centralized servers. TACACS+ allows a client to accept a username and password and send a query to a TACACS+ authentication server. The server host determines whether to accept or deny the request and sends a response back that allows or denies the user access to the network.

TACACS+ offers fully encrypted packet bodies, and supports both IP and AppleTalk protocols. TACACS+ uses TCP port 49, which is seen as more reliable than RADIUS’s UDP protocol.

There are several different authentication protocols that TACACS+ can use during the authentication process:

Authentication protocols

Protocol	Definition
ASCII	Machine-independent technique that uses representations of English characters. Requires user to type a username and password that are sent in clear text (unencrypted) and matched with an entry in the user database stored in ASCII format.
PAP	Password Authentication Protocol (PAP) Used to authenticate PPP connections. Transmits passwords and other user information in clear text.
CHAP	Challenge-Handshake Authentication Protocol (CHAP) Provides the same functionality as PAP, but is more secure as it does not send the password and other user information over the network to the security server.

Protocol	Definition
MS-CHAP	MicroSoft Challenge-Handshake Authentication Protocol v1 (MSCHAP) Microsoft-specific version of CHAP.
default	The default protocol configuration, Auto, uses PAP, MS-CHAP, and CHAP, in that order.

Configuring a TACACS+ server on the FortiGate unit

A maximum of 10 remote TACACS+ servers can be configured for authentication.

One or more servers must be configured on FortiGate before remote users can be configured. To configure remote users, see Local and remote users on page 561.

The TACACS+ page in the web-based manager is not available until a TACACS+ server has been configured in the CLI. For more information see the CLI Reference.

To configure the FortiGate unit for TACACS+ authentication - web-based manager:

1. Go to **User & Device > Authentication > TACACS+ Servers** and select **Create New**.
2. Enter the following information, and select **OK**.

Name	Enter the name of the TACACS+ server.
Server Name/IP	Enter the server domain name or IP address of the TACACS+ server.
Server Key	Enter the key to access the TACACS+ server.
Authentication Type	Select the authentication type to use for the TACACS+ server. **Auto** tries PAP, MSCHAP, and CHAP (in that order).

To configure the FortiGate unit for TACACS+ authentication - CLI:

```
config user tacacs+
   edit tacacs1
      set authen-type auto
      set key abcdef
      set port 49
      set server 192.168.0.101
   end
```

POP3 servers

FortiOS can authenticate users who have accounts on POP3 or POP3s email servers. POP3 authentication can be configured only in the CLI.

To configure the FortiGate unit for POP3 authentication:

```
config user pop3
   edit pop3_server1
      set server pop3.fortinet.com
      set secure starttls
      set port 110
```

```
    end
```

To configure a POP3 user group:

```
config user group
   edit pop3_grp
      set member pop3_server1
   end
```

A user group can list up to six POP3 servers as members.

SSO servers

Novell and Microsoft Windows networks provide user authentication based on directory services: eDirectory for Novell, Active Directory for Windows. Users can log on at any computer in the domain and have access to resources as defined in their user account. The Fortinet Single Sign On (FSSO) agent enables FortiGate units to authenticate these network users for security policy or VPN access without asking them again for their username and password.

When a user logs in to the Windows or Novell domain, the FSSO agent sends to the FortiGate unit the user's IP address and the names of the user groups to which the user belongs. The FortiGate unit uses this information to maintain a copy of the domain controller user group database. Because the domain controller authenticates users, the FortiGate unit does not perform authentication. It recognizes group members by their IP address.

In the FortiOS FSSO configuration, you specify the server where the FSSO Collector agent is installed. The Collector agent retrieves the names of the Novell or Active Directory user groups from the domain controllers on the domains, and then the FortiGate unit gets them from the Collector agent. You cannot use these groups directly. You must define FSSO type user groups on your FortiGate unit and then add the Novell or Active Directory user groups to them. The FSSO user groups that you created are used in security policies and VPN configurations to provide access to different services and resources.

FortiAuthenticator servers can replace the Collector agent when FSSO is using polling mode. The benefits of this is that FortiAuthenticator is a stand-alone server that has the necessary FSSO software pre-installed. For more information, see the FortiAuthenticator Administration Guide.

Single Sign-on Agent configuration settings

The following are SSO configuration settings in **User & Device > Authentication > Single Sign-On**.

SSO Server List

Lists all the collector agents' lists that you have configured. On this page, you can create, edit or delete FSSO agents. There are different types of FSSO agents, each with its own settings.

Note: You can create a redundant configuration on your unit if you install a collector agent on two or more domain controllers. If the current (or first) collector agent fails, the Fortinet unit switches to the next one in its list of up to five collector agents.

Create New	Creates a new agent. When you select **Create New**, you are automatically redirected to the New page.

Edit	Modifies the settings for the selected SSO server. To remove multiple entries from the list, for each servers you want removed, select the check box and then select **Delete**. To remove all agents from the list, on the FSSO Agent page, select the check box at the top of the check box column and then select **Delete**.
Delete	Removes an agent from the list on the page.

Settings when Type is Poll Active Directory Server	
Server IP/Name	The IP address of the domain controller (DC).
User	The user ID used to access the domain controller.
Password	Enter the password for the account used to access the DC.
LDAP Server	Select the check box and select an LDAP server to access the Directory Service.
Enable Polling	Enable to allow the FortiGate unit to poll this DC.
Users/Groups	A list of user and user group names retrieved from the DC.

Settings when Type is Fortinet Single Sign On Agent	
Name	Enter a name for the SSO server.
Primary Agent IP/Name **Secondary Agent IP/Name**	Enter the IP address or name of the Directory Service server where this SSO agent is installed. The maximum number of characters is 63.
Password	Enter the password for the collector agent. This is required only if you configured your Fortinet Single Sign On Agent collector agent to require authenticated access.
LDAP Server	Select the check box and select an LDAP server to access the Directory Service.
More FSSO agents	Select to add up to three additional SSO agents.
Users/Groups	A list of user and user group names retrieved from the server.

Settings when Type is RADIUS Single Sign On Agent	
Use RADIUS Shared Secret	Enable

Settings when Type is RADIUS Single Sign On Agent	
Shared Secret	Enter the RADIUS server shared secret.
Send RADIUS Responses	Enable.

RSA ACE (SecurID) servers

SecurID is a two-factor system that uses one-time password (OTP) authentication. It is produced by the company RSA. This system includes portable tokens carried by users, an RSA ACE/Server, and an Agent Host. In our configuration, the FortiGate unit is the Agent Host.

Components

When using SecurID, users carry a small device or "token" that generates and displays a pseudo-random password. According to RSA, each SecurID authenticator token has a unique 64-bit symmetric key that is combined with a powerful algorithm to generate a new code every 60 seconds. The token is time-synchronized with the SecurID RSA ACE/Server.

The RSA ACE/Server is the management component of the SecurID system. It stores and validates the information about the SecurID tokens allowed on your network. Alternately the server could be an RSA SecurID 130 Appliance.

The Agent Host is the server on your network, in this case it is the FortiGate unit, that intercepts user logon attempts. The Agent Host gathers the user ID and password entered from their SecurID token, and sends that information to the RSA ACE/Server to be validated. If valid, a reply comes back indicating it is a valid logon and the FortiGate unit allows the user access to the network resources specified in the associated security policy.

Configuring the SecurID system

To use SecurID with a FortiGate unit, you need:

- to configure the RSA server and the RADIUS server to work with each other (see RSA server documentation)
- to configure the RSA SecurID 130 Appliance
  or
- to configure the FortiGate unit as an Agent Host on the RSA ACE/Server
- to configure the FortiGate unit to use the RADIUS server
- to create a SecurID user group
- to configure a security policy with SecurID authentication

The following instructions are based on RSA ACE/Server version 5.1, or RSA SecurID 130 Appliance, and assume that you have successfully completed all the external RSA and RADIUS server configuration steps listed above.

For this example, the RSA server is on the internal network, with an IP address of 192.128.100.100. The FortiGate unit internal interface address is 192.168.100.3, RADIUS shared secret is fortinet123, RADIUS server is at IP address 192.168.100.102.

To configure the RSA SecurID 130 Appliance

1. Go to the IMS Console for SecurID and logon.
2. Go to **RADIUS > RADIUS Clients**, and select **Add New.**

3. Enter the following information to configure your FortiGate as a SecurID Client, and select Save.

RADIUS Client Basics	
Client Name	FortiGate
Associated RSA Agent	FortiGate

RADIUS Client Settings	
IP Address	192.168.100.3 The IP address of the FortiGate unit internal interface.
Make / Model	Select Standard Radius
Shared Secret	fortinet123 The RADIUS shared secret.
Accounting	Leave unselected
Client Status	Leave unselected

To configure the FortiGate unit as an Agent Host on the RSA ACE/Server

1. On the RSA ACE/Server computer, go to **Start > Programs > RSA ACE/Server**, and then **Database Administration - Host Mode**.
2. On the **Agent Host** menu, select **Add Agent Host**.
3. Enter and save the following information.

Name	FortiGate
Network Address	192.168.100.3 The IP address of the FortiGate unit.
Secondary Nodes	Optionally enter other IP addresses that resolve to the FortiGate unit.

If needed, refer to the RSA ACE/Server documentation for more information.

To configure the FortiGate unit to use the RADIUS server

1. Go to **User & Device > Authentication > RADIUS Servers** and select **Create New**.
2. Enter the following information, and select **OK**.

Name	RSA

Primary Server IP/Name	192.168.100.102 Optionally select Test to ensure the IP address is correct and the FortiGate can contact the RADIUS server.
Primary Server Secret	fortinet123
Authentication Scheme	Select **Use Default Authentication Scheme**.

To create a SecurID user group

1. Go to **User & Device > User > User Groups**, and select **Create New**.
2. Enter the following information.

Name	RSA_group
Type	Firewall

3. In **Remote Groups**, select **Add**, then select the RSA server.
4. Select **OK**.

To create a SecurID user:

1. Go to **User & Device > User > User Definition**, and select **Create New**.
2. Use the wizard to enter the following information, and then select **Create**.

User Type	Remote RADIUS User
User Name	wloman
RADIUS Server	RSA
Contact Info	(optional) Enter Email or SMS information
User Group	RSA_group

To test this configuration, on your FortiGate unit use the CLI command:

```
diagnose test authserver radius RSA auto wloman 111111111
```

The series of 1s is the one time password that your RSA SecurID token generates and you enter.

Using the SecurID user group for authentication

You can use the SecurID user group in several FortiOS features that authenticate by user group including

- Security policy
- IPsec VPN XAuth
- PPTP VPN
- SSL VPN

The following sections assume the SecurID user group is called `securIDgrp` and has already been configured. Unless otherwise states, default values are used.

Security policy

To use SecurID in a security policy, you must include the SecurID user group in a security policy. This procedure will create a security policy that allows HTTP, FTP, and POP3 traffic from the `internal` interface to `wan1`. If these interfaces are not available on your FortiGate unit, substitute other similar interfaces.

To configure a security policy with SecurID authentication

1. Go to **Policy & Objects > Policy > IPv4**.
2. Select **Create New**.
3. Enter:

Incoming Interface	internal
Source Address	all
Source User(s)	securIDgrp
Outgoing Interface	wan1
Destination Address	all
Schedule	always
Services	HTTP, FTP, POP3
Action	ACCEPT
NAT	On
Shared Shaper	On, if you want to either limit traffic or guarantee minimum bandwidth for traffic that uses the SecurID security policy. Use the default shaper **guarantee-100kbps**.
Log Allowed Traffic	On, if you want to generate usage reports on traffic authenticated with this policy.

4. Select **OK**.
   The SecurID security policy is configured.

For more detail on configuring security policies, see the FortiOS Handbook FortiGate Fundamentals guide.

IPsec VPN XAuth

Extended Authentication (XAuth) increases security by requiring user authentication in addition to the preshared key.

When creating an IPsec VPN using the wizard (**VPN > IPsec > Wizard**), select the SecurID **User Group** on the Authentication page. Members of the SecurID group are required to enter their SecureID code to authenticate.

For more on XAuth, see Configuring XAuth authentication on page 602

PPTP VPN

PPTP VPN is configured in the CLI. In the PPTP configuration (`config vpn pptp`), set `usrgrp` to the SecurID user group.

SSL VPN

You need to map the SecurID user group to the portal that will serve SecurID users and include the SecurID user group in the **Source User(s)** field in the security policy.

To map the SecurID group to an SSL VPN portal:

1. Go to **VPN > SSL > Settings**.
2. In **Authentication/Portal Mapping**, select **Create New**.
3. Enter

Users/Groups	securIDgrp
Portal	Choose the portal.

4. Select **OK**.

Users and user groups

FortiGate authentication controls system access by user group. By assigning individual users to the appropriate user groups you can control each user's access to network resources. The members of user groups are user accounts, of which there are several types. Local users and peer users are defined on the FortiGate unit. User accounts can also be defined on remote authentication servers.

This section describes how to configure local users and peer users and then how to configure user groups. For information about configuration of authentication servers see Authentication servers on page 537.

This section contains the following topics:

- Users
- User groups

Users

A user is a user account consisting of username, password, and in some cases other information, configured on the FortiGate unit or on an external authentication server. Users can access resources that require authentication only if they are members of an allowed user group. There are several different types of user accounts with slightly different methods of authentication:

User type	Authentication
Local user	The username and password must match a user account stored on the FortiGate unit. Authentication by FortiGate security policy.
Remote user	The username must match a user account stored on the FortiGate unit and the username and password must match a user account stored on the remote authentication server. FortiOS supports LDAP, RADIUS, and TACACS+ servers.
Authentication server user	A FortiGate user group can include user accounts or groups that exist on a remote authentication server.
FSSO user	With Fortinet Single Sign On (FSSO), users on a Microsoft Windows or Novell network can use their network authentication to access resources through the FortiGate unit. Access is controlled through FSSO user groups which contain Windows or Novell user groups as their members.
PKI or Peer user	A Public Key Infrastructure (PKI) or peer user is a digital certificate holder who authenticates using a client certificate. No password is required, unless two-factor authentication is enabled.
IM Users	IM users are not authenticated. The FortiGate unit can allow or block each IM user name from accessing the IM protocols. A global policy for each IM protocol governs access to these protocols by unknown users.
Guest Users	Guest user accounts are temporary. The account expires after a selected period of time.

This section includes:

- Local and remote users
- PKI or peer users
- Two-factor authentication
- FortiToken
- Monitoring users

Local and remote users

Local and remote users are defined on the FortiGate unit in **User & Device > User > User Definition**.

Create New	Creates a new user account. When you select **Create New**, you are automatically redirected to the User Creation Wizard.
Edit User	Modifies a user's account settings. When you select **Edit**, you are automatically redirected to the Edit User page.
Delete	Removes a user from the list. Removing the user name removes the authentication configured for the user. The **Delete** icon is not available if the user belongs to a user group. To remove multiple local user accounts from within the list, on the User page, in each of the rows of user accounts you want removed, select the check box and then select **Delete**. To remove all local user accounts from the list, on the User page, select the check box in the check box column and then select **Delete**.
User Name	The user name. For a remote user, this username must be identical to the username on the authentication server.
Type	Local indicates a local user authenticated on the FortiGate unit. For remote users, the type of authentication server is shown: LDAP, RADIUS, or TACACS+.
Two-factor Authentication	Indicates whether two-factor authentication is configured for the user.
Ref.	Displays the number of times this object is referenced by other objects. Select the number to open the Object Usage window and view the list of referring objects. The list is grouped into expandable categories, such as Firewall Policy. Numbers of objects are shown in parentheses. To view more information about the referring object, use the icons: • **View the list page for these objects** – available for object categories. Goes to the page where the object is listed. For example, if the category is User Groups, opens User Groups list. • **Edit this object** – opens the object for editing. • **View the details for this object** – displays current settings for the object.

To create a local or remote user account - web-based manager:

1. Go to **User & Device > User > User Definition** and select **Create New**.
2. On the **Choose User Type** page select:

Local User	Select to authenticate this user using a password stored on the FortiGate unit.
Remote RADIUS User **Remote TACACS+ User** **Remote LDAP User**	To authenticate this user using a password stored on an authentication server, select the type of server and then select the server from the list. You can select only a server that has already been added to the FortiGate unit configuration.

3. Select **Next** and provide user authentication information.
   For a local user, enter the **User Name** and **Password**.
   For a remote user, enter the **User Name** and the server name.
4. Select **Next** and enter **Contact Information**.
   If email or SMS is used for two-factor authentication, provide the email address or SMS cell number at which the user will receive token password codes. If a custom SMS service is used, it must already be configured in **System > Config > Advanced >SMS Service**. See FortiToken on page 567.
5. Select **Next**, then on the **Provide Extra Info** page enter

Two-factor Authentication	Select to enable two-factor authentication. Then select the Token (FortiToken or FortiToken Mobile) for this user account. See Associating FortiTokens with accounts on page 571.
User Group	Select the user groups to which this user belongs.

6. Select **Create**.

To create a local user - CLI example:

Locally authenticated user

```
config user local
   edit user1
      set type password
      set passwd ljt_pj2gpepfdw
   end
```

To create a remote user - CLI example:

```
config user local
   edit user2
      set type ldap
      set ldap_server ourLDAPsrv
   end
```

For a RADIUS or TACACS+ user, set `type` to `radius` or `tacacs+`, respectively.

To create a user with FortiToken Mobile two-factor authentication - CLI example:

```
config user local
```

```
edit user5
   set type password
   set passwd ljt_pj2gpepfdw
   set two_factor fortitoken
   set fortitoken 182937197
end
```

Remote users are configured for FortiToken two-factor authentication similarly.

To create a user with SMS two-factor authentication using FortiGuard messaging Service - CLI example:

```
config user local
   edit user6
      set type password
      set passwd 3ww_pjt68dw
      set two_factor sms
      set sms-server fortiguard
      set sms-phone 1365984521
   end
```

Removing users

Best practices dictate that when a user account is no longer in use, it should be deleted. Removing local and remote users from FortiOS involve the same steps.

If the user account is referenced by any configuration objects, those references must be removed before the user can be deleted. See Removing references to users on page 563.

To remove a user from the FortiOS configuration - web-based manager:

1. Go to **User & Device > User > User Definition**.
2. Select the check box of the user that you want to remove.
3. Select **Delete**.
4. Select **OK**.

To remove a user from the FortiOS configuration - CLI example:

```
config user local
   delete user4444
end
```

Removing references to users

You cannot remove a user that belongs to a user group. Remove the user from the user group first, and then delete the user.

To remove references to a user - web-based manager

1. Go to **User & Device > User > User Definition**.
2. If the number in the far right column for the selected user contains any number other than zero, select it.
3. A more detailed list of object references to this user is displayed. Use its information to find and remove these references to allow you to delete this user.

PKI or peer users

A PKI, or peer user, is a digital certificate holder. A PKI user account on the FortiGate unit contains the information required to determine which CA certificate to use to validate the user's certificate. Peer users can be included in firewall user groups or peer certificate groups used in IPsec VPNs. For more on certificates, see Certificates overview on page 615.

To define a peer user you need:

- a peer username
- the text from the subject field of the user's certificate, or the name of the CA certificate used to validate the user's certificate

Creating a peer user

The peer user can be configured only in the CLI.

To create a peer user for PKI authentication - CLI example:

```
config user peer
   edit peer1
      set subject peer1@mail.example.com
      set ca CA_Cert_1
   end
```

There are other configuration settings that can be added or modified for PKI authentication. For example, you can configure the use of an LDAP server to check access rights for client certificates. For information about the detailed PKI configuration settings, see the FortiGate CLI Reference.

Two-factor authentication

The standard logon requires a username and password. This is one factor authentication—your password is one piece of information you need to know to gain access to the system.

Two factor authentication adds the requirement for another piece of information for your logon. Generally the two factors are something you know (password) and something you have (certificate, token, etc.). This makes it harder for a hacker to steal your logon information. For example if you have a FortiToken device, the hacker would need to both use it and know your password to gain entry to your account.

Two-factor authentication is available on both user and admin accounts. But before you enable two-factor authentication on an administrator account, you need to ensure you have a second administrator account configured to guarantee administrator access to the FortiGate unit if you are unable to authenticate on the main admin account for some reason.

Two-factor authentication does not work with explicit proxies.

The methods of two-factor authentication include:

- Certificate
- Email

- SMS
- FortiToken

Certificate

You can increase security by requiring both certificate and password authentication for PKI users. Certificates are installed on the user's computer. Requiring a password also protects against unauthorized use of that computer.

Optionally peer users can enter the code from their FortiToken instead of the certificate.

To create a peer user with two-factor authentication - CLI example

```
config user peer
   edit peer1
      set subject E=peer1@mail.example.com
      set ca CA_Cert_1
      set two-factor enable
      set passwd fdktguefheygfe
   end
```

For more information on certificates, see Certificates overview on page 615.

Email

Two-factor email authentication sends a randomly generated six digit numeric code to the specified email address. Enter that code when prompted at logon. This token code is valid for 60 seconds. If you enter this code after that time,it will not be accepted.

A benefit is that you do not require mobile service to authenticate. However, a potential issue is if your email server does not deliver the email before the 60 second life of the token expires.

The code will be generated and emailed at the time of logon, so you must have email access at that time to be able to receive the code.

To configure an email provider - web-based manager:

1. Go to **System > Config > Advanced > Email Service**.
2. Enter **SMTP Server** and **Default Reply To** address.
3. If applicable, enable **Authentication** and enter the **SMTP User** and **Password** to use.
4. Select a **Security Mode**, options are: **None**, **SMTPS** or **STARTTLS**.
5. Enter the **Port** number, the default is 25.
6. Select **Apply**.

To configure an email provider - CLI:

```
config system email-server
   set server <server_domain-name>
   set reply-to <Recipient_email_address>
end
```

To enable email two-factor authentication - web-based manager:

1. To modify an administrator account, go to **System > Admin > Administrators**. To modify a user account go to **User & Device > User > User Definition**.

2. Edit the user account.
3. Enable and enter the user's **Email Address**.
4. Select **Enable Two-factor Authentication**.
5. Select **Email based two-factor authentication**.
6. Select **OK**.

If **Email based two-factor authentication** option doesn't appear after selecting **Enable Two-factor Authentication**, you need to enable it via the CLI as follows.

To enable email two-factor authentication - CLI:

```
config user local
   edit <user_name>
      set email-to <user_email>
      set two-factor email
   end
```

SMS

SMS two-factor authentication sends the token code in an SMS text message to the mobile device indicated when this user attempts to logon. This token code is valid for 60 seconds. If you enter this code after that time, it will not be accepted. Enter this code when prompted at logon to be authenticated.

SMS two-factor authentication has the benefit that you do not require email service before logging on. A potential issue is if the mobile service provider does not send the SMS text message before the 60 second life of the token expires.

FortiGuard Messaging Service include 4 SMS Messages at no cost. If you need more, you should acquire a license through support.fortinet.com or via customer service.

If you do not use the FortiGuard Messaging Service, you need to configure an SMS service.

To configure an SMS service for your FortiGate unit - web-based manager:

1. Go to **System > Config > Advanced**.
2. In **SMS Service**, select **Create New**.
3. Enter a **Name** for the SMS service and the service **Address** (domain name), then select **OK**.
4. Select **Apply**.

To configure an SMS service - CLI:

```
config system sms-server
   edit <provider_name>
      set mail-server <server_domain-name>
   next
end
```

To configure SMS two-factor authentication - web-based manager:

1. To modify an:
   - administrator account, go to **System > Admin > Administrators, or**
   - user account go to **User & Device > User > User Definition**.
2. Edit the user account.

3. Select SMS and either:
   - Select **FortiGuard Messaging Service**
     or
   - Select **Custom** and then choose the **SMS Provider** to use.
4. Select the **Country/Region**.
5. Enter the phone number of the mobile device that will receive the SMS text messages.
6. Select **Enable Two-factor Authentication**.
7. Select **SMS based two-factor authentication**.
8. Select **OK**.

If **SMS based two-factor authentication** option doesn't appear after selecting **Enable Two-factor Authentication**, you need to enable it via the CLI as follows.

To enable SMS two-factor authentication - CLI:

```
config user local
   edit <user_name>
      set sms-phone <user_phone>
      set sms-server fortiguard
      set two-factor sms
   end
```

If you have problems receiving the token codes via SMS messaging, contact your mobile provider to ensure you are using the correct phone number format to receive text messages and that your current mobile plan allows text messages.

FortiToken

FortiToken is a disconnected one-time password (OTP) generator. It is a small physical device with a button that when pressed displays a six digit authentication code. This code is entered with a user's username and password as two-factor authentication. The code displayed changes every 60 seconds, and when not in use the LCD screen is blanked to extend the battery life.

There is also a mobile phone application, FortiToken Mobile, that performs much the same function.

FortiTokens have a small hole in one end. This is intended for a lanyard to be inserted so the device can be worn around the neck, or easily stored with other electronic devices. Do not put the FortiToken on a key ring as the metal ring and other metal objects can damage it. The FortiToken is an electronic device like a cell phone and must be treated with similar care.

Any time information about the FortiToken is transmitted, it is encrypted. When the FortiGate unit receives the code that matches the serial number for a particular FortiToken, it is delivered and stored encrypted. This is in keeping with the Fortinet's commitment to keeping your network highly secured.

FortiTokens can be added to user accounts that are local, IPsec VPN, SSL VPN, and even Administrators. See Associating FortiTokens with accounts on page 571.

A FortiToken can be associated with only one account on one FortiGate unit.

If a user loses their FortiToken, it can be locked out using the FortiGate so it will not be used to falsely access the network. Later if found, that FortiToken can be unlocked on the FortiGate to allow access once again. See FortiToken maintenance on page 572.

There are three tasks to complete before FortiTokens can be used to authenticate accounts:

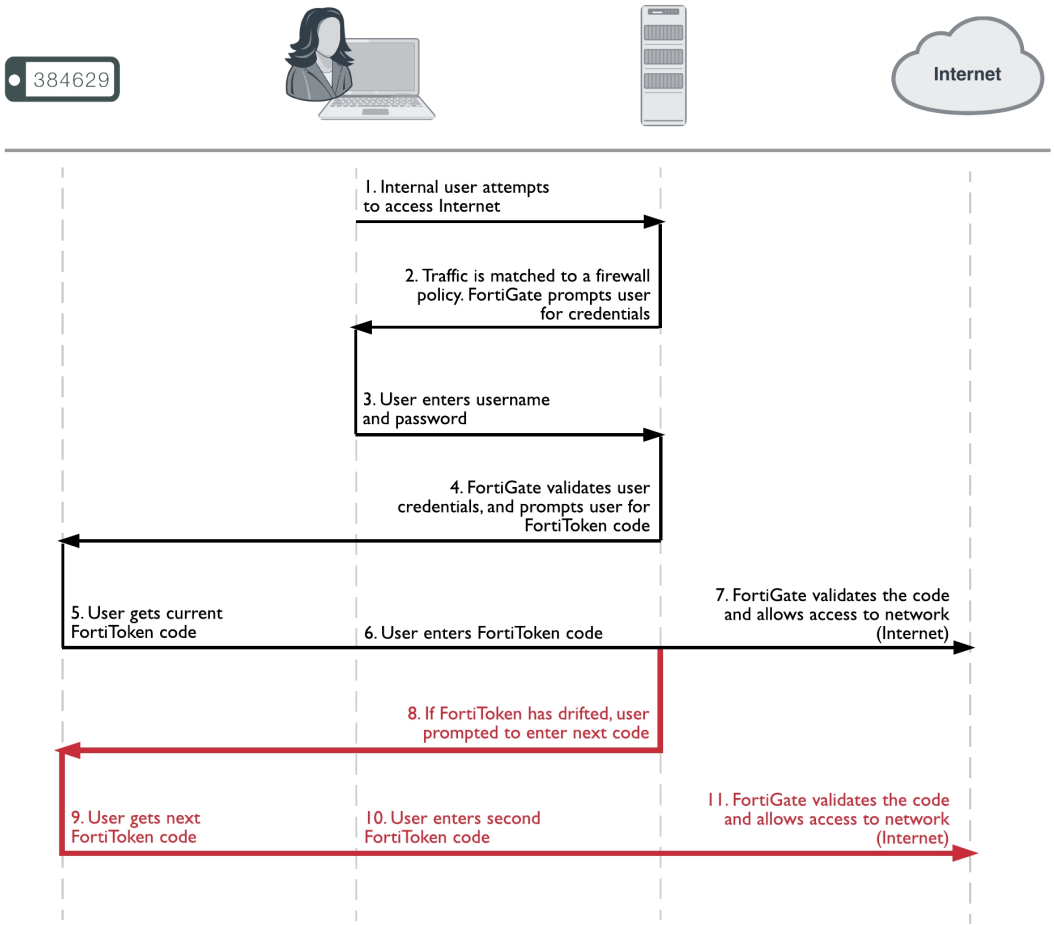
1. Adding FortiTokens to the FortiGate
2. Activating a FortiToken on the FortiGate
3. Associating FortiTokens with accounts

The FortiToken authentication process

The steps during FortiToken two-factor authentication are as follows.

1. User attempts to access a network resource.
2. FortiGate unit matches the traffic to an authentication security policy, and FortiGate unit prompts the user for username and password.
3. User enters their username and password.
4. FortiGate unit verifies their information, and if valid prompts the user for the FortiToken code.
5. User gets the current code from their FortiToken device.
6. User enters current code at the prompt.
7. FortiGate unit verifies the FortiToken code, and if valid allows access to the network resources such as the Internet.
   The following steps are needed only if the time on the FortiToken has drifted and needs to be re-synchronized with the time on the FortiGate unit.
8. If time on FortiToken has drifted, FortiGate unit will prompt user to enter a second code to confirm.
9. User gets the next code from their FortiToken device
10. User enters the second code at the prompt.
11. FortiGate unit uses both codes to update its clock to match the FortiToken and then proceeds as in step "Users and user groups" on page 560.

The FortiToken authentication process is illustrated below:



When configured the FortiGate unit accepts the username and password, authenticates them either locally or remotely, and prompts the user for the FortiToken code. The FortiGate then authenticates the FortiToken code. When FortiToken authentication is enabled, the prompt field for entering the FortiToken code is automatically added to the authentication screens.

Even when an Administrator is logging in through a serial or Telnet connection and their account is linked to a FortiToken, that Administrator will be prompted for the token's code at each login.

If you have attempted to add invalid FortiToken serial numbers, there will be no error message. The serial numbers will simply not be added to the list.

Adding FortiTokens to the FortiGate

Before one or more FortiTokens can be used to authenticate logons, they must be added to the FortiGate. The import feature is used to enter many FortiToken serial numbers at one time. The serial number file must be a text file with one FortiToken serial number per line.

Both FortiToken Mobile and physical FortiTokens store their encryption seeds on the cloud, therefore you will only be able to register them to a single FortiGate or FortiAuthenticator.

Because FortiToken-200CD seed files are stored on the CD, these tokens can be registered on multiple FortiGates and/or FortiAuthenticators, but **not** simultaneously.

To manually add a FortiToken to the FortiGate - web-based manager:

1. Go to **User & Device > FortiTokens**.
2. Select **Create New**.
3. In **Type**, select **Hard Token** or **Mobile Token**.
4. Enter one or more FortiToken serial numbers (hard token) or activation codes (mobile token).
5. Select **OK**.

For mobile token, you receive the activation code in the license certificate once you purchase a license. FortiOS include a license for two mobile token at no cost.

To import multiple FortiTokens to the FortiGate - web-based manager:

1. Go to **User & Device > FortiTokens**.
2. Select **Create New**.
3. In **Type**, select **Hard Token**.
4. Select **Import**.
5. Select **Serial Number File** or **Seed File**, depending on which file you have.
6. Browse to the local file location on your local computer.
7. Select **OK**.
   The file is imported.
8. Select **OK**.

To add two FortiTokens to the FortiGate - CLI:

```
config user fortitoken
   edit <serial_number>
   next
   edit <serial_number2>
   next
end
```

Activating a FortiToken on the FortiGate

Once one or more FortiTokens have been added to the FortiGate unit, they must be activated before being available to be associated with accounts.The process of activation involves the FortiGate querying FortiGuard servers about the validity of each FortiToken. The serial number and information is encrypted before it is sent for added security.

A FortiGate unit requires a connection to FortiGuard servers to activate a FortiToken.

To activate a FortiToken on the FortiGate unit - web-based manager:

1. Go to **User & Device > FortiTokens**.
2. Select one or more FortiTokens with a status of Available.
3. Right-click the FortiToken entry and select **Activate**.
4. Select **Refresh**.
   The status of selected FortiTokens will change to Activated.

The selected FortiTokens are now available for use with user and admin accounts.

To activate a FortiToken on the FortiGate unit - CLI:

```
config user fortitoken
   edit <token_serial_num>
      set status activate
   next
end
```

Associating FortiTokens with accounts

The final step before using the FortiTokens to authenticate logons is associating a FortiToken with an account. The accounts can be local user or administrator accounts.

To add a FortiToken to a local user account - web-based manager:

1. Ensure that your FortiToken serial number has been added to the FortiGate successfully, and its status is Available.
2. Go to **User & Device > User > User Definition**, and edit the user account.
3. Select **Email Address** and enter user's email address.
4. Select **Enable Two-factor Authentication**.
5. Select the user's FortiToken serial number from the **Token** list.
6. Select **OK**.

For mobile token, click on **Send Activation Code**to be sent to the email address configured previously. The user will use this code to activate his mobile token. An **Email Service** has to be set under **System > Config > Advanced**in order to send the activation code.

To add a FortiToken to a local user account - CLI:

```
config user local
   edit <username>
      set type password
      set passwd "myPassword"
      set two-factor fortitoken
      set fortitoken <serial_number>
      set email-to "username@example.com"
```

```
      set status enable
   next
   end
```

To add a FortiToken to an administrator account - web-based manager:

1. Ensure that your FortiToken serial number has been added to the FortiGate successfully, and its status is Available.
2. Go to **System > Admin > Administrators**, and edit the admin account.
   This account is assumed to be configured except for two-factor authentication.
3. Select **Email Address** and enter admin's email address.
4. Select **Enable Two-factor Authentication**.
5. Select the user's FortiToken serial number from the **Token** list.
6. Select **OK**.

For mobile token, click on **Send Activation Code**to be sent to the email address configured previously. The admin will use this code to activate his mobile token. An **Email Service** has to be set under **System > Config > Advanced**in order to send the activation code.

To add a FortiToken to an administrator account - CLI:

```
config system admin
   edit <username>
      set password "myPassword"
      set two-factor fortitoken
      set fortitoken <serial_number>
      set email-to "username@example.com"
   next
   end
```

The `fortitoken` keyword will not be visible until `fortitoken` is selected for the `two-factor` option.

Before a new FortiToken can be used, it may need to be synchronized due to clock drift.

FortiToken maintenance

Once FortiTokens are entered into the FortiGate unit, there are only two tasks to maintain them — changing the status,

To change the status of a FortiToken between Activated and Locked - CLI:

```
config user fortitoken
   edit <token_serial_num>
      set status lock
   next
end
```

Any user attempting to login using this FortiToken will not be able to authenticate.

To list the drift on all FortiTokens configured on this FortiGate unit - CLI:

```
# diag fortitoken info
FORTITOKEN DRIFT STATUS
FTK2000BHV1KRZCC 0 token already activated, and seed won't be returned
FTK2001C5YCRRVEE 0 token already activated, and seed won't be returned
FTKMOB4B94972FBA 0 provisioned
FTKMOB4BA4BE9B84 0 new
Total activated token: 0
Total global activated token: 0
Token server status: reachable
```

This command lists the serial number and drift for each FortiToken configured on this FortiGate unit. This command is useful to check if it is necessary to synchronize the FortiGate and any particular FortiTokens.

Monitoring users

To monitor user activity in the web-based manager, go to **User & Device > Monitor > Firewall**. The list of users who are logged on is displayed with some information about them such as their user group, security policy ID, how long they have been logged on, their IP address, traffic volume, and their authentication method as one of FSSO, NTLM, or firewall (FW-auth).

From this screen you can de-authenticate all users who are logged on. The de-authenticate button is at the top left of this screen.

To see information about banned users go to **User & Device > Monitor > Banned User**. Displayed information about users who have been banned includes what application the triggered the ban (Application Protocol), the reason for the ban (Cause or rule), Created, and when the ban expires.

Filtering the list of users

When there are many users logged on, it can be difficult to locate a specific user or multiple users to analyze. Applying filters to the list allows you to organize the user list to meet your needs, or only display some the users that meet your current requirements.

Select settings bottom at the top right of the screen to adjust columns that are displayed for users, including what order they are displayed in. This can be very helpful in locating information you are looking for.

Each column heading has a grey filter icon. Click on the filter icon to configure a filter for the data displayed in that column. Each column has similar options including a field to enter the filtering information, a check box to select the negative of the text in the field, and the options to add more fields, apply the filter, clear all filters, or cancel without saving. To enter multiple terms in the field, separate each of them with a comma. To filter entries that contain a specific prefix, use an * (asterisk).

For example, to create a filter to display only users with an IP address of `10.11.101.x` who authenticated using one of security policies five through eight, and who belong to the user group `Accounting`.

1. Go to **User & Device > Monitor > Firewall**.
2. Select the filter icon beside **IP address**.
3. Enter `10.11.101.*` and select **Apply**.
4. Select the filter icon beside **Policy ID.**
5. Enter `5-8` and select **Apply**.
6. Select the filter icon beside **User Group.**
7. Enter `Accounting` and select **Apply**.

User groups

A user group is a list of user identities. An identity can be:

- a local user account (username/password stored on the FortiGate unit
- a remote user account (password stored on a RADIUS, LDAP, or TACACS+ server)
- a PKI user account with digital client authentication certificate stored on the FortiGate unit
- a RADIUS, LDAP, or TACACS+ server, optionally specifying particular user groups on that server
- a user group defined on an FSSO server.

Security policies and some types of VPN configurations allow access to specified user groups only. This restricted access enforces Role Based Access Control (RBAC) to your organization's network and its resources. Users must be in a group and that group must be part of the security policy.

In most cases, the FortiGate unit authenticates users by requesting their username and password. The FortiGate unit checks local user accounts first. If a match is not found, the FortiGate unit checks the RADIUS, LDAP, or TACACS+ servers that belong to the user group. Authentication succeeds when a matching username and password are found. If the user belongs to multiple groups on a server, those groups will be matched as well.

FortiOS does not allow username overlaps between RADIUS, LDAP, or TACACS+ servers.

There are four types of FortiGate user groups: Firewall, Fortinet Single Sign-On (FSSO), Guest, and RADIUS Single Sign-On (RSSO) user groups.

Firewall user groups

Firewall user groups are used locally as part of authentication. When a security policy allows access only to specified user groups, users must authenticate. If the user authenticates successfully and is a member of one of the permitted groups, the session is allowed to proceed.

This section includes:

- SSL VPN access
- IPsec VPN access
- Configuring a firewall user group
- Multiple group enforcement support
- User group timeouts

SSL VPN access

SSL VPN settings include a list of the firewall user groups that can access the SSL VPN and the SSL VPN portal that each group will use. When the user connects to the FortiGate unit via HTTPS on the SSL VPN port (default 10443), the FortiGate unit requests a username and password.

SSL VPN access also requires a security policy where the destination is the SSL interface. For more information, see the FortiOS Handbook SSL VPN guide.

IPsec VPN access

A firewall user group can provide access for dialup users of an IPsec VPN. In this case, the IPsec VPN phase 1 configuration uses the **Accept peer ID in dialup group** peer option. The user's VPN client is configured with the username as peer ID and the password as pre-shared key. The user can connect successfully to the IPsec VPN only if the username is a member of the allowed user group and the password matches the one stored on the FortiGate unit.

A user group cannot be used as a dialup group if any member of the group is authenticated using an external authentication server.

For more information, see the FortiOS Handbook IPsec VPN guide.

Configuring a firewall user group

A user group can contain:

- local users, whether authenticated by the FortiGate unit or an authentication server
- PKI users
- authentication servers, optionally specifying particular user groups on the server

To create a Firewall user group - web-based manager:

1. Go to **User & Device > User > User Groups** and select **Create New**.
2. Enter a name for the user group.
3. In **Type**, select **Firewall**.
4. Add user names to to the **Members** list.
5. Add authentication servers to the **Remote groups** list.
   By default all user accounts on the authentication server are members of this FortiGate user group. To include only specific user groups from the authentication server, deselect **Any** and enter the group name in the appropriate format for the type of server. For example, an LDAP server requires LDAP format, such as: cn=users,dn=office,dn=example,dn=com
   Remote servers must already be configured in **User & Device > Authentication**.
6. Select **OK**.

To create a firewall user group - CLI example:

In this example, the members of `accounting_group` are `User1` and all of the members of `rad_accounting_group` on `myRADIUS` external RADIUS server.

```
config user group
   edit accounting_group
      set group-type firewall
      set member User1 myRADIUS
      config match
         edit 0
            set server-name myRADIUS
            set group-name rad_accounting_group
         end
      end
```

Matching user group names from an external authentication server might not work if the list of group memberships for the user is longer than 8000 bytes. Group names beyond this limit are ignored.

`server_name` is the name of the RADIUS, LDAP, or TACACS+ server, but it must be a member of this group first and must also be a configured remote server on the FortiGate unit.

`group_name` is the name of the group on the RADIUS, LDAP, or TACACS+ server such as “engineering” or “cn=users,dc=test,dc=com”.

Before using group matching with TACACS+, you must first enable authentication. For example if you have a configured TACACS+ server called myTACS, use the following CLI commands.

```
config user tacacs+
   edit myTACS
   set authorization enable
   next
end
```

For more information about user group CLI commands, see the Fortinet CLI Guide.

Multiple group enforcement support

Previously, when a user belonged to multiple user groups, this user could only access the group services that were within one group. With multiple group enforcement, a user can access the services within the groups that the user is part of.

For example, `userA` belongs to `user_group1`, `user_group2`, `user_group3`, and `user_group4`; previously `userA` could only access services within one of those four groups, typically the group that matches the first security policy. This can be annoying if HTTP access is in `user_group1`, FTP access is in `user_group2`, and email access is in `user_group3`. Now `userA` can access services within `user_group1`, `user_group2`, `user_group3`, and `user_group4`.

This feature is available only in the CLI and is enabled by default. It applies to RADIUS, LDAP, and TACACS+ servers. The new command for this feature is `auth-multi-group` found in `config user settings` and checks all groups a user belongs to for authentication.

User group timeouts

User groups can have timeout values per group in addition to FortiGate-wide timeouts. There are essentially three different types of timeouts that are configurable for user authentication on the FortiGate unit — idle timeout, hard timeout, and session timeout. These are in addition to any external timeouts such as those associated with RADIUS servers.

If VDOMs are enabled, the global level user setting `authtimeout` is the default all VDOMs inherit. If VDOMs are not enabled, user settings authtimeout is the default. The default timeout value is used when the `authtimeout` keyword for a user group is set to zero.

Each type of timeout will be demonstrated using the existing user group `example_group`. Timeout units are minutes. A value of zero indicates the global timeout is used.

Membership in multiple groups

When a user belongs to multiple groups in RADIUS groups, the group auth-timeout values are ignored. Instead the global timeout value is used. The default value is 5 minutes, but it can be set from 1 to 1440 minutes (24 hours).

```
config user setting
   set auth-timeout-type idle-timeout
   set auth-timeout 300
end
```

Idle timeout

The default type of timeout is idle timeout. When a user initiates a session, it starts a timer. As long as data is transferred in this session, the timer continually resets. If data flow stops, the timer is allowed to advance until it reaches its limit. At that time the user has been idle for too long, and the user is forced to re-authenticate before traffic is allowed to continue in that session.

To configure user group authentication idle timeout - CLI:

```
config user settings
   set auth-timeout-type idle-timeout
end
config user group
   edit example_group
      set authtimeout 5 //range is 0-1440 minutes (0 = use global authtimeout value)
   next
end
```

Hard timeout

Where the idle timeout is reset with traffic, the hard timeout is absolute. From the time the first session a user establishes starts, the hard timeout counter starts. When the timeout is reached, all the sessions for that user must be re-authenticated. This timeout is not affected by any event.

To configure user group authentication hard timeout - CLI:

```
config user settings
   set auth-timeout-type hard-timeout
end
config user group
   edit example_group
      set authtimeout 1440 //range is 0-1440 minutes (0 = use global authtimeout value)
   next
end
```

Session timeout

The session timeout works much like the hard timeout in that its an absolute timer that can not be affected by events. However, when the timeout is reached existing sessions may continue but new sessions are not allowed until re-authentication takes place.

To configure a user group authentication new session hard timeout - CLI:

```
config user setting
```

```
   set auth-timeout-type new-session
end

config user group
   edit example_group
      set authtimeout 30 //range is 0-1440 minutes (0 = use global authtimeout value)
   next
end
```

SSO user groups

SSO user groups are part of FSSO authentication and contain only Windows or Novell network users. No other user types are permitted as members. Information about the Windows or Novell user groups and the logon activities of their members is provided by the Fortinet Single Sign On (FSSO) which is installed on the network domain controllers.

You can specify FSSO user groups in security policies in the same way as you specify firewall user groups. FSSO user groups cannot have SSL VPN or dialup IPsec VPN access.

For information about configuring FSSO user groups, see Creating Fortinet Single Sign-On (FSSO) user groups on page 683. For complete information about installing and configuring FSSO, see Agent-based FSSO on page 646.

Configuring Peer user groups

Peer user groups can only be configured using the CLI. Peers are digital certificate holders defined using the `config user peer` command. The peer groups you define here are used in dialup IPsec VPN configurations that accept RSA certificate authentication from members of a peer certificate group.

To create a peer group - CLI example:

```
config user peergrp
   edit vpn_peergrp1
      set member pki_user1 pki_user2 pki_user3
   end
```

Viewing, editing and deleting user groups

To view the list of FortiGate user groups, go to **User & Device > User > User Groups**.

Editing a user group

When editing a user group in the CLI you must set the type of group this will be — either a firewall group, a Fortinet Single Sign-On Service group (FSSO), a Radius based Single Sign-On Service group (RSSO), or a guest group. Once the type of group is set, and members are added you cannot change the group type without removing the members.

In the web-based manager, if you change the type of the group any members will be removed automatically.

To edit a user group - web-based manager:

1. Go to **User & Device > User > User Groups**.
2. Select the user group that you want to edit.
3. Select the **Edit** button.

4. Modify the user group as needed.
5. Select **OK**.

To edit a user group - CLI example:

This example adds user3 to Group1. Note that you must re-specify the full list of users:

```
config user group
   edit Group1
   set group-type firewall
      set member user2 user4 user3
   end
```

Deleting a user group

Before you delete a user group, you must ensure there are no objects referring to, it such as security policies. If there are, you must remove those references before you are able to delete the user group.

To remove a user group - web-based manager:

1. Go to **User & Device > User > User Groups**.
2. Select the user group that you want to remove.
3. Select the **Delete** button.
4. Select **OK**.

To remove a user group - CLI example:

```
config user group
   delete Group2
end
```

Managing Guest Access

Visitors to your premises might need user accounts on your network for the duration of their stay. If you are hosting a large event such as a conference, you might need to create many such temporary accounts. The FortiOS Guest Management feature is designed for this purpose.

A guest user account User ID can be the user's email address, a randomly generated string, or an ID that the administrator assigns. Similarly, the password can be administrator-assigned or randomly generated.

You can create many guest accounts at once using randomly-generated User IDs and passwords. This reduces administrator workload for large events.

User's view of guest access

1. The user receives an email, SMS message, or printout from a FortiOS administrator listing a User ID and password.
2. The user logs onto the network with the provided credentials.
3. After the expiry time, the credentials are no longer valid.

Administrator's view of guest access

1. Create one or more guest user groups.
   All members of the group have the same characteristics: type of User ID, type of password, information fields used, type and time of expiry.
2. Create guest accounts using Guest Management.
3. Use captive portal authentication and select the appropriate guest group.

Configuring guest user access

To set up guest user access, you need to create at least one guest user group and add guest user accounts. Optionally, you can create a guest management administrator whose only function is the creation of guest accounts in specific guest user groups. Otherwise, any administrator can do guest management.

Creating guest management administrators

To create a guest management administrator

1. Go to **System > Admin > Administrators** and create a regular administrator account.
   For detailed information see the System Administration chapter.
2. Select **Restrict to Provision Guest Accounts**.
3. In **Guest Groups**, add the guest groups that this administrator manages.

Creating guest user groups

The guest group configuration determines the fields that are provided when you create a guest user account.

To create a guest user group:

1. Go to **User & Device > User > User Groups** and select **Create New**.
2. Enter the following information:

Name	Enter a name for the group.
Type	Guest
Enable Batch Account Creation	Create multiple accounts automatically. When this is enabled: • **User ID** and **Password** are set to **Auto-Generate**. • The user accounts have only **User ID, Password**, and **Expiration** fields. Only the **Expiration** field is editable. If the expiry time is a duration, such as "8 hours", this is the time after first login. • You can print the account information. Users do not receive email or SMS notification. See To create multiple guest user accounts automatically on page 582.
User ID	Select one of: • Email — User's email address • Specify — Administrator assigns user ID • Auto-Generate — FortiGate unit creates a random user ID
Password	Select one of: • Specify — Administrator assigns user ID • Auto-Generate — FortiGate unit creates a random password • Disable — no password
Expire Type	Choose one of: • Immediately — expiry time is counted from creation of account • After first login — expiry time is counted from user's first login
Default Expire Time	Set the expire time. The administrator can change this for individual users.
Enable Name	If enabled, user must provide a name.
Enable Sponsor	If enabled, user form has Sponsor field. Select **Required** if required.
Enable Company	If enabled, user form has Company field. Select **Required**if required.
Enable Email	If enabled, user is notified by email.
Enable SMS	If enabled, user is notified by SMS. Select whether FortiGuard Messaging Service or a another SMS provider is used. You can add SMS providers in **System > Config > Messaging Servers**.

Creating guest user accounts

Guest user accounts are not the same as local user accounts created in **User & Device > User > User Definition**. Guest accounts are not permanent; they expire after a defined time period. You create guest accounts in **User & Device > User > Guest Management**.

To create a guest user account

1. Go to **User & Device > User > Guest Management.**
2. In **Guest Groups**, select the guest group to manage.

3. Select **Create New** and fill in the fields in the **New User** form.
   Fields marked Optional can be left blank. The guest group configuration determines the fields that are available.
4. Select **OK**.

To create multiple guest user accounts automatically

1. Go to **User & Device > User > Guest Management.**
2. In **Guest Groups**, select the guest group to manage.
   The guest group must have the **Enable Batch Guest Account Creation** option enabled.
3. Select **Create New > Multiple Users**.
   Use the down-pointing caret to the right of **Create New**.
4. Enter **Number of Accounts**.
5. Optionally, change the **Expiration**.
6. Select **OK**.

Guest Management Account List

Go to **User & Device > User > Guest Management** to create, view, edit or delete guest user accounts.

Create New	Creates a new guest user account.
Edit	Edit the selected guest user account.
Delete	Delete the selected guest user account.
Purge	Remove all expired accounts from the list.
Send	Send the user account information to a printer or to the guest. Depending on the group settings and user information, the information can be sent to the user by email or SMS.
Refresh	Update the list.
Guest Groups	Select the guest group to list. New accounts are added to this group.
User ID	The user ID. Depending on the guest group settings, this can be the user's email address, an ID that the administrator specified, or a randomly-generated ID.
Expires	Indicates a duration such as "3 hours". A duration on its own is relative to the present time. Or, the duration is listed as "after first login."

Guest access in a retail environment

Some retail businesses such as coffee shops provide free Wi-Fi Internet access for their customers. For this type of application, the FortiOS guest management feature is not required; the Wi-Fi access point is open and customers do not need logon credentials. However, the business might want to contact its customers later with promotional offers to encourage further patronage. Using an Email Collection portal, it is possible to collect customer email addresses for this purpose. The security policy grants network access only to users who provide a valid email address.

The first time a customer's device attempts to use the Wi-Fi connection, FortiOS requests an email address, which it validates. The customer's subsequent connections go directly to the Internet without interruption.

Creating an email harvesting portal

The customer's first contact with your network will be with a captive portal which presents a web page requesting an email address. When FortiOS has validated the email address, the customer's device MAC address is added to the Collected Emails device group.

To create the email collection portal:

1. Go to **WiFi & Switch Controller > WiFi Network > SSID** and edit your SSID.
2. Set **Security Mode** to **Captive Portal**.
3. Set **Portal Type** to **Email Collection**.
4. Optionally, in **Customize Portal Messages** select **Email Collection.**

You can change the portal content and appearance. See Customizing captive portal pages on page 608.

To create the email collection portal - CLI:

In this example the `freewifi` Wi-Fi interface is modified to present an email collection captive portal.

```
config wireless-controller vap
   edit freewifi
      set security captive-portal
      set portal-type email-collect
end
```

Creating the security policy

You need configure a security policy that allows traffic to flow from the Wi-Fi SSID to the Internet interface but only for members of the Collected Emails device group. This policy must be listed first. Unknown devices are not members of the Collected Emails device group, so they do not match the policy.

To create the security policy:

1. Go to **Policy & Objects > Policy > IPv4** and select **Create New**.
2. Enter the following information:

Incoming Interface	freewifi
Source Address	all
Source Device Type	Collected Emails
Outgoing Interface	wan1
Destination Address	all
Schedule	always
Service	ALL

Action	ACCEPT
NAT	On

3. Select **OK**.

To create the authentication rule - CLI:

```
config firewall policy
   edit 3
      set srcintf "freewifi"
      set dstintf "wan1"
      set srcaddr "all"
      set action accept
      set devices collected-emails
      set nat enable
      set schedule "always"
      set service "ALL"
   end
```

Checking for harvested emails

In the web-based manager, go to **User & device > Device > Device Definitions**. In the CLI you can use the `diagnose user device list` command. For example,

```
FGT-100D # diagnose user device list
hosts
   vd 0 d8:d1:cb:ab:61:0f gen 35 req 30 redir 1 last 43634s 7-11_2-int
      ip 10.0.2.101 ip6 fe80::dad1:cbff:feab:610f
      type 2 'iPhone' src http c 1 gen 29
      os 'iPhone' version 'iOS 6.0.1' src http id 358 c 1
      email 'yo@yourdomain.com'
   vd 0 74:e1:b6:dd:69:f9 gen 36 req 20 redir 0 last 39369s 7-11_2-int
      ip 10.0.2.100 ip6 fe80::76e1:b6ff:fedd:69f9
      type 1 'iPad' src http c 1 gen 5
      os 'iPad' version 'iOS 6.0' src http id 293 c 1
      host 'Joes's-iPad' src dhcp
      email 'you@fortinet.com'
```

Fall-through authentication policies

User authentication policies have an implicit fall-through feature that intentionally causes policy matching to fall through to a policy lower on the list that can also match the traffic. In other words the first user policy that is matched in the policy list, based on standard policy criteria, isn't the only policy that can be matched.

Fall-through is intended to match users in different user groups with different policies. For example, consider an organization with two user groups where one group requires a web filtering profile, while the other requires virus scanning. In this example, you would edit two basic Internet access policies: policy 1 assigning **User Group A** with a **Web Filtering** profile, and policy 2 assigning **User Group B** with an **AntiVirus** profile. Both policies are also assigned to the same internal subnet, named **subnet1**.

In this configuration, all users from **subnet1** will see an authentication prompt. If the user is found in **User Group A**, the traffic is accepted by policy 1 and is filtered by the **Web Filtering** profile. If the user is found in **User Group B**, the traffic is accepted by policy 2 and is virus scanned.

The fall-through feature is required for users to be matched with policy 2. Without the fall-through feature, traffic would never be matched with policy 2.

Configuring authenticated access

When you have configured authentication servers, users, and user groups, you are ready to configure security policies and certain types of VPNs to require user authentication.

This section describes:

- Authentication timeout
- Password policy
- Authentication protocols
- Authentication in Captive Portals
- Authentication in security policies
- VPN authentication

Authentication timeout

An important feature of the security provided by authentication is that it is temporary—a user must re-authenticate after logging out. Also if a user is logged on and authenticated for an extended period of time, it is a good policy to have them re-authenticate at set periods. This ensures a user's session is cannot be spoofed and used maliciously for extended periods of time — re-authentication will cut any spoof attempts short. Shorter timeout values are more secure.

Security authentication timeout

You set the security user authentication timeout to control how long an authenticated connection can be idle before the user must authenticate again. The maximum timeout is 1440 minutes (24 hours).

To set the security authentication timeout - web-based manager:

1. Go to **User & Device > Authentication > Settings**.
2. Enter the **Authentication Timeout** value in minutes.
   The default authentication timeout is 5 minutes.
3. Select **Apply**.

SSL VPN authentication timeout

You set the SSL VPN user authentication timeout (**Idle Timeout**) to control how long an authenticated connection can be idle before the user must authenticate again. The maximum timeout is 259 200 seconds. The default timeout is 300 seconds.

To set the SSL VPN authentication timeout - web-based manager:

1. Go to **VPN > SSL > Settings**.
2. Under **Idle Logout**, make sure that **Logout users when inactive for specified period** is enabled and enter the **Inactive For** value (seconds).
3. Select **Apply**.

Password policy

Password authentication is effective only if the password is sufficiently strong and is changed periodically. By default, the FortiGate unit requires only that passwords be at least eight characters in length, but up to 128 characters is permitted. You can set a password policy to enforce higher standards for both length and complexity of passwords. Password policies can apply to administrator passwords or IPsec VPN preshared keys.

To set a password policy in the web-based manager, go to **System > Admin > Settings**. In the CLI, use the `config system password-policy` command.

Users usually create passwords composed of alphabetic characters and perhaps some numbers. Password policy can require the inclusion of uppercase letters, lowercase letters, numerals or punctuation characters.

Configuring password minimum requirement policy

Best practices dictate that passwords include:

- one or more uppercase characters
- one or more lower case characters
- one or more of the numerals
- one or more special characters.

The minimum number of each of these types of characters can be set in both the web-based manager and the CLI.

The following procedures show how to force administrator passwords to contain at least two uppercase, four lower care, two digits, and one special character. Leave the minimum length at the default of eight characters.

To change administrator password minimum requirements - web-based manager:

1. Go to **System > Admin > Settings**.
2. Select **Enable Password Policy**.
3. Select **Must Contain at Least**.
4. Enter the following information:

Upper Case Letters	2
Lower Case Letters	4
Numbers	2
Special Characters	1

5. Under **Apply Password Policy to**, select **Administrator Password**.
6. Select **Apply**.

To change administrator password minimum requirements - CLI:

```
config system password-policy
   set status enable
   set apply-to admin-password
   set min-upper-case-letter 2
   set min-lower-case-letter 4
```

```
    set min-number 2
    set min-non-alphanumeric 1
    set change-4-characters enable
end
```

The `change-4-characters` option forces new passwords to change a minimum of four characters in the old password. Changing fewer characters results in the new password being rejected. This option is only available in the CLI.

Password best practices

In addition to length and complexity, there are security factors that cannot be enforced in a policy. Guidelines issued to users will encourage proper password habits.

Best practices dictate that password expiration also be enabled. This forces passwords to be changed on a regular basis. You can set the interval in days. The more sensitive the information this account has access to, the shorter the password expiration interval should be. For example 180 days for guest accounts, 90 days for users, and 60 days for administrators.

Avoid:

- real words found in any language dictionary
- numeric sequences, such as “12345”
- sequences of adjacent keyboard characters, such as “qwerty”
- adding numbers on the end of a word, such as “hello39”
- adding characters to the end of the old password, such as “hello39” to “hello3900”
- repeated characters
- personal information, such as your name, birthday, or telephone number.

Maximum logon attempts and blackout period

When you logon and fail to enter the correct password you could be a valid user, or a hacker attempting to gain access. For this reason, best practices dictate to limit the number of failed attempts to logon before a blackout period where you cannot logon.

To set a maximum of five failed authentication attempts before the blackout, using the following CLI command:

```
config user setting
    set auth-invalid-max 5
end
```

To set the length of the blackout period to five minutes, or 300 seconds, once the maximum number of failed logon attempts has been reached, use the following CLI command:

```
config user setting
    set auth-blackout-time 300
end
```

Authentication protocols

When user authentication is enabled on a security policy, the authentication challenge is normally issued for any of the four protocols, HTTP, HTTPS, FTP, and Telnet, which are dependent on the connection protocol. By making selections in the Protocol Support list, the user controls which protocols support the authentication

challenge. The user must connect with a supported protocol first, so that they can subsequently connect with other protocols.

For example, if you have selected HTTP, FTP, or Telnet, a username and password-based authentication occurs. The FortiGate unit then prompts network users to input their security username and password. If you have selected HTTPS, certificate-based authentication (HTTPS, or HTTP redirected to HTTPS only) occurs.

FTP and Telnet authentication replacement messages cannot be customized. For HTTP and HTTPS replacement messages see Authentication replacement messages on page 590.

For certificate-based authentication, you must install customized certificates on the FortiGate unit and on the browsers of network users. If you do not install certificates on the network user's web browser, the network users may see an SSL certificate warning message and have to manually accept the default FortiGate certificate. The network user's web browser may deem the default certificate as invalid.

When you use certificate authentication, if you do not specify any certificate when you create the security policy, the global settings are used. If you specify a certificate, the per-policy setting will overwrite the global setting. For more information about the use of certification authentication see Certificate-based authentication on page 614.

To set the authentication protocols

1. Go to **User & Device > Authentication > Settings**.
2. In **Protocol Support**, select the required authentication protocols.
3. If using HTTPS protocol support, in **Certificate**, select a Local certificate from the drop-down list.
4. Select **Apply**.

Authentication in Captive Portals

Network interfaces, including WiFi interfaces, can perform authentication at the interface level using a captive portal — an HTML form that requests the user's name and password. A captive portal is useful where all users connecting to the network interface must authenticate. Optionally, on a WiFi interface, the captive portal can be combined with a terms of service disclaimer to which the user must agree before gaining access. For more information, see Captive portals on page 606.

Once successfully authenticated, the user's session passes to the firewall.

Authentication in security policies

Security policies control traffic between FortiGate interfaces, both physical interfaces and VLAN subinterfaces. The firewall tries to match the session's user or group identity, device type, destination, etcetera to a security policy. When a match is found, the user connects to the requested destination. If no security policy matches, the user is denied access.

A user who has not already been authenticated by a captive portal, FSSO, or RSSO can match only policies where no user or user group is specified. If no such policy exists, the firewall requests authentication. If the user can authenticate and the session can be matched to a policy, the user connects to the requested destination, otherwise, the user is denied access.

This section includes:

- Enabling authentication protocols
- Authentication replacement messages
- Access to the Internet
- Configuring authentication security policies
- Identity-based policy
- NTLM authentication
- Certificate authentication
- Restricting number of concurrent user logons

Enabling authentication protocols

Users can authenticate using FTP, HTTP, HTTPS, and Telnet. However, these protocols must be enabled first.

Another authentication option is to redirect any attempts to authenticate using HTTP to a more secure channel that uses HTTPS. This forces users to a more secure connection before entering their user credentials.

To enable support for authentication protocols - web-based manager:

1. Go to **User & Device > Authentication > Settings**.
2. Select one or more of HTTP, HTTPS, FTP, Telnet, or Redirect HTTP Challenge to a Secure Channel (HTTPS). Only selected protocols will be available for use in authentication.
3. Select the **Certificate** to use, for example `Fortinet_Factory`.
4. Select **Apply**.

To enable support for authentication protocols - CLI:

```
config user setting
   set auth-type ftp http https telnet
   set auth-cert Fortinet_Factory
end
```

Authentication replacement messages

A replacement message is the body of a webpage containing a message about a blocked website message, a file too large message, a disclaimer, or even a login page for authenticating. The user is presented with this message instead of the blocked content.

Authentication replacement messages are the prompts a user sees during the security authentication process such as login page, disclaimer page, and login success or failure pages. These are different from most replacement messages because they are interactive requiring a user to enter information, instead of simply informing the user of some event as other replacement messages do.

Replacement messages have a system-wide default configuration, a per-VDOM configuration, and disclaimers can be customized for multiple security policies within a VDOM.

These replacement messages are used for authentication using HTTP and HTTPS. Authentication replacement messages are HTML messages. You cannot customize the security authentication messages for FTP and Telnet.

The authentication login page and the authentication disclaimer include replacement tags and controls not found on other replacement messages.

More information about replacement messages can be found in the `config system replacemsg` section of the FortiOS CLI Reference.

List of authentication replacement messages

Replacement message name (CLI name)	Description
Login challenge page (auth-challenge-page)	This HTML page is displayed if security users are required to answer a question to complete authentication. The page displays the question and includes a field in which to type the answer. This feature is supported by RADIUS and uses the generic RADIUS challenge-access auth response. Usually, challenge-access responses contain a Reply-Message attribute that contains a message for the user (for example, “Please enter new PIN”). This message is displayed on the login challenge page. The user enters a response that is sent back to the RADIUS server to be verified. The Login challenge page is most often used with RSA RADIUS server for RSA SecurID authentication. The login challenge appears when the server needs the user to enter a new PIN. You can customize the replacement message to ask the user for a SecurID PIN. This page uses the %%QUESTION%% tag.
Disclaimer page (auth-disclaimer-page-1) (auth-disclaimer-page-2) (auth-disclaimer-page-3)	This page prompts user to accept the displayed disclaimer when leaving the captive portal to access Internet resources. It is displayed when the captive portal type is **Authentication and Disclaimer** or **Disclaimer Only**. In the CLI, the auth-disclaimer-page-2 and auth-disclaimer-page-3 pages seamlessly extend the size of the disclaimer page from 8 192 characters to 16 384 and 24 576 characters respectively. In the web-based manager this is handled automatically. See Disclaimer on page 593.
Email token page (auth-email-token-page)	The page prompting a user to enter their email token. See Email on page 1.
FortiToken page (auth-fortitoken-page)	The page prompting a user to enter their FortiToken code. See FortiToken on page 567.

Replacement message name (CLI name)	Description

Keepalive page (auth-keepalive-page)	The HTML page displayed with security authentication keepalive is enabled using the following CLI command:
	
	`config system globalset auth-keepalive enable`
	`end`
	
	Authentication keepalive keeps authenticated firewall sessions from ending when the authentication timeout ends. In the web-based manager, go to **User & Device > Authentication > Settings** to set the **Authentication Timeout**.
	
	This page includes %%TIMEOUT%%.

Login failed page (auth-login-failed-page)	The Disclaimer page replacement message does not re-direct the user to a redirect URL or the security policy does not include a redirect URL. When a user selects the button on the disclaimer page to decline access through the FortiGate unit, the Declined disclaimer page is displayed.
Login page (auth-login-page)	The authentication HTML page displayed when users who are required to authenticate connect through the FortiGate unit using HTTP or HTTPS. Prompts the user for their username and password to login. This page includes %%USERNAMEID%% and %%PASSWORDID%% tags.
Declined disclaimer page (auth-reject-page)	The page displayed if a user declines the disclaimer page. See Disclaimer on page 593.
SMS Token page (auth-sms-token-page)	The page prompting a user to enter their SMS token. See SMS on page 566.
Success message (auth-success-msg)	The page displayed when a user successfully authenticates. Prompts user to attempt their connection again (as the first was interrupted for authentication).

Access to the Internet

A policy for accessing the Internet is similar to a policy for accessing a specific network, but the destination address is set to **all**. The destination interface is the one that connects to the Internet Service Provider (ISP). For general purpose Internet access, the Service is set to ALL.

Access to HTTP, HTTPS, FTP and Telnet sites may require access to a domain name service. DNS requests do not trigger authentication. You must configure a policy to permit unauthenticated access to the appropriate DNS server, and this policy must **precede** the policy for Internet access. Failure to do this will result in the lack of a DNS connection and a corresponding lack of access to the Internet.

Configuring authentication security policies

To include authentication in a security policy, the policy must specify user groups. A security policy can authenticate by certificate, FSSO, and NTLM. The two exceptions to this are RADIUS SSO and FSSO Agents. See SSO using RADIUS accounting records on page 691, and Introduction to FSSO agents on page 647.

Before creating a security policy, you need to configure one or more users or user groups. For more information, see Users and user groups on page 560.

Creating the security policy is the same as a regular security policy except you must select the action specific to your authentication method:

Authentication methods allowed for each policy Action

Action	Authentication method	Where authentication is used
ACCEPT	FSSO Agent or a security policy that specifies an FSSO user group	Agent-based FSSO on page 646.
	NTLM	See NTLM authentication on page 595.
	Certificates	See Configuring certificate-based authentication on page 626.
	RADIUS SSO	See SSO using RADIUS accounting records on page 691.
DENY	none	none

Disclaimer

A WiFi or SSL captive portal can include a disclaimer message presented after the user authenticates. The user must agree to the terms of the disclaimer to access network resources.

Customizing authentication replacement messages

Customizing disclaimers or other authentication replacement messages involves changing the text of the disclaimer message, and possibly the overall appearance of the message.

Changing the disclaimer in **System > Config > Replacement messages** is not the same as selecting to customize a disclaimer used in a captive portal. The **System > Config** location is the default message that all disclaimers inherit. The captive portal location is a customized disclaimer that inherits the default format for the disclaimer message, but then can be customized for this portal.

To customize the disclaimer for a captive portal - web-based manager:

1. Go to **System > Network > Interface**. Either select an existing interface or create a new one.
2. Under **Security Mode**, select **Captive Portal**, and enable **Customize Portal Messages**.
3. Select the **Edit** icon. You can select and edit any of the pages. Change your text or layout as needed.

Enabling security logging

There are two types of logging that relate to authentication — event logging, and security logging.

When enabled, event logging records system events such as configuration changes, and authentication. To configure event logging, go to **Log&Report > Log Config > Log Settings** and enable **Event Logging**. Select the events you want to log, such as **User activity event**.

When enabled, security logging will log security profile and security policy traffic.

You must enable logging within a security policy, as well as the options that are applied to a security policy, such as security profiles features. Event logs are enabled within the Event Log page.

For more information on logging, see the FortiOS Log and Reporting guide.

For more information on specific types of log messages, see the FortiOS Log Message Reference.

You need to set the logging severity level to **Notification** when configuring a logging location to record traffic log messages.

To enable logging within an existing security policy - web-based manager:

1. Go to **Policy & Objects > Policy > IPv4**.
2. Expand to reveal the policy list of a policy.
3. Select the security policy you want to enable logging on and then select **Edit**.
4. To log all general firewall traffic, select the check box beside **Log Allowed Traffic**, and choose to enable **Security Events** or **All Sessions**.
5. Select **OK**.

Identity-based policy

An identity-based policy (IBP) performs user authentication in addition to the normal security policy duties. If the user does not authenticate, access to network resources is refused. This enforces Role Based Access Control (RBAC) to your organization's network and resources.

Identity-based policies also support Single Sign-On operation. The user groups selected in the policy are of the Fortinet Single Sign-On (FSSO) type.

User authentication can occur through any of the following supported protocols, including: HTTP, HTTPS, FTP, and Telnet. The authentication style depends on which of these protocols is included in the selected security services group and which of those enabled protocols the network user applies to trigger the authentication challenge.

For username and password-based authentication (HTTP, FTP, and Telnet) the FortiGate unit prompts network users to enter their username, password, and token code if two-factor authentication is selected for that user account. For certificate-based authentication, including HTTPS or HTTP redirected to HTTPS only, see Certificate authentication on page 600.

With identity-based policies, the FortiGate unit allows traffic that matches the source and destination addresses, device types, and so on. This means specific security policies must be placed **before** more general ones to be effective.

When the identity-based policy has been configured, the option to customize authentication messages is available. This allows you to change the text, style, layout, and graphics of the replacement messages associated with this firewall policy. When enabled, customizing these messages follows the same method as changing the disclaimer. See Disclaimer on page 593.

Types of authentication also available in identity-based policies are

- NTLM authentication
- Certificate authentication

NTLM authentication

NT LAN Manager (NTLM) protocol can be used as a fallback for authentication when the Active Directory (AD) domain controller is unreachable. NTLM uses the web browser to send and receive authentication information. See "NTLM" and "FSSO NTLM authentication support".

To enable NTLM

1. Edit the policy in the CLI to enable NTLM. For example, if the policy ID is 4:
2. Go to **Policy & Objects > Policy > IPv4** and note the **ID** number of your FSSO policy.
3. The policy must have an FSSO user group as **Source User(s)**. There must be at least one FSSO Collector agent configured on the FortiGate unit.

```
config firewall policy
   edit 4
      set ntlm enable
   end
```

NTLM guest access

Guest profile access may be granted to users who fail NTLM authentication, such as visitors who have no user credentials on the network. To allow guest user access, edit the FSSO security policy in the CLI, like this:

```
config firewall policy
   edit 4
      set ntlm enable
      set ntlm-guest enable
   end
```

NTLM enabled browsers - CLI

User agent strings for NTLM enabled browsers allow the inspection of initial HTTP-User-Agent values, so that non-supported browsers are able to go straight to guest access without needlessly prompting the user for credentials that will fail. `ntlm-guest` must be enabled to use this option.

```
config firewall policy
   edit 4
      set ntlm enable
      set ntlm-guest enable
      set ntlm-enabled-browsers <user_agent_string>
   next
   end
```

`<user_agent_string>` is the name of the browser that is NTLM enabled. Examples of these values include “MSIE”, “Mozilla” (which includes FireFox), and “Opera”.

Value strings can be up to 63 characters in length, and may not contain cross site scripting (XSS) vulnerability characters such as brackets. The FortiGate unit prevents use of these characters to prevent exploit of cross site scripting (XSS) vulnerabilities.

Kerberos authentication for explicit proxy users

Kerberos authentication is a new method for authenticating explicit proxy users. It has several advantages over NTLM challenge response:

- Does not require FSSO/AD agents to be deployed across domains.
- Requires fewer round-trips than NTLM SSO, making it less latency sensitive.
- Is (probably) more scalable than challenge response.
- Uses existing Windows domain components rather than added components.
- NTLM may still be used as a fallback for non-Kerberos clients.

1. General configuration

1.1 Kerberos environment - Windows server setup

1. Build a Windows 2008 Platform server.
2. Enable domain configuration in windows server (dcpromo).
3. Set the domain name TEST.COM (realm name).

1.2 Create users

- *testuser* is a normal user (could be any existing domain user account).
- *testfgt* is the service name. In this case it should be the FQDN for the explicit proxy Interface, For example the hostname in the client browser proxy config.
- Recommendation: create username all in lowercase (even if against corporate standards).
  - The account only requires “domain users” membership
  - Password set to never expire
  - Set a very strong password

1.3 Add FortiGate to DNS

Add the FortiGate FQDN in to the Windows DNS domain, as well as in-addr.arpa

For Lab/Testing add the FortiGate Domain name and IP mapping in the hosts file (windows/system32/drivers/etc/hosts). e.g., `TESTFGT.TEST.COM 10.10.1.10`

1.4 Generate the Kerberos keytab

Use the *ktpass* command (found on Windows Servers and many domain workstations) to generate the Kerberos keytab.

Example:

```
ktpass -princ HTTP/<domain name of test fgt>@realm -mapuser testfgt -pass <password> -
    crypto all -ptype KRB5_NT_PRINCIPAL -out fgt.keytab
```

The ktpass on older Windows servers (i.e. 2003) may not support the “all” crypto option.

Example:

```
ktpass -princ HTTP/testfgt.test.com@TEST.COM -mapuser testfgt -pass 12345678 -crypto all -
    ptype KRB5_NT_PRINCIPAL -out fgt.keytab
```

The realm name is always presented in uppercase, and prefixed with the “@” character.

1.5 Encode base64

Use the *base64* command (available in most Linux distros) command to encode the *fgt.keytab* file. Any LF (Line Feed) need to be deleted from the file.

Example:

```
base64 fgt.keytab > fgt.txt
```

Use Notepad++ or some native Linux text editor. Windows Notepad and Wordpad are likely to introduce errors.

2. FortiGate configuration

2.1 Create LDAP Server instance

```
config user ldap
   edit "ldap" <<< Required for authorization
      set server "10.10.1.1" <<< LDAP server IP, normally it should be same as KDC server
      set cnid "cn"
      set dn "dc=test,dc=com"
      set type regular
      set username "CN=admin,CN=Users,DC=test,DC=com" <<< Your domain may require STARTTLS
      set password <FOOS>
   next
end
```

2.2 Define Kerberos as an authentication service

```
config user krb-keytab
   edit "http_service"
      set principal "HTTP/testfgt.test.com@TEST.COM" <<< Same as the principal name in 1.4
      set ldap-server "ldap" <<< the defined ldap server for authoriztion
      set keytab
          "BQIAAABNAAIACkJFUkJFUi5DT00ABEhUVFAAGlRPTllfRkdUXzEwMERfQS5CRVJCRVIuQ09NAAAAAQA
          AAAAKABcAEJQl0MHqovwplu7XzfENJzw=" <<< base64 endoding keytab data, created in step 1.5
   next
end
```

2.3 Create user gorup(s)

```
config user group <<< the group is used for kerberos authentication
   edit "testgrp"
      set member "ldap"
      config match
         edit 1
            set server-name "ldap" <<< Same as ldap-server option in krb-keytab
            set group-name "CN=Domain Users,CN=Users,DC=TEST,DC=com"
         next
      end
   next
end
```

2.4 Create firewall policy

```
config firewall explicit-proxy-policy
   edit 1
      set uuid 5e5dd6c4-952c-51e5-b363-120ad77c1414
      set proxy web
      set dstintf "wan1"
      set srcaddr "all"
      set dstaddr "all"
      set service "webproxy"
      set action accept
      set identity-based enable
      set webcache enable
      set comments "test"
      set active-auth-method negotiate <<< Accepts both Kerberos and NTLM as fallback
      config identity-based-policy
         edit 1
            set schedule "always"
            set groups "testgrp"
         next
      end
   next
end
```

2.5 Diagnostics

Once the keytab is imported, check that it has been properly decoded. The filename generated will be relatively random, but should be clearly visible.

```
Artoo-Deetoo (root) # fnsysctl ls -la /tmp/kt
drwxr--r-- 2  0   0 Fri Dec 2 10:06:43 2016    60 .
drwxrwxrwt 22 0   0 Tue Dec 6 14:28:29 2016    3280 ..
-rw-r--r-- 1  0   0 Fri Dec 2 10:06:43 2016    392 1.0.89.keytab
```

If there is no file present, then the file hasn't decoded. Check the file for line feeds and try again.

3. Client side walkthrough

3.1 Check Kerberos is working

Log on to the domain by using *testuser*, created in 1.2. Use the *klist* command to list ticket information. In the below example, the client has received *krbtgt*, *CIFS*, and *LDAP* tickets. As there has been no interaction with the FortiGate, there are no references to it.

```
C:\Users\glenk>klist Cached Tickets: (5)

C:\Users\glenk>klist
Cached Tickets: (5)
#0> Client: glenk @ home.local

      Server: krbtgt/HOME.LOCAL @ HOME.LOCAL
      KerbTicket Encryption Type: AES-256-CTS-HMAC-SHA1-96
      Ticket Flags 0x60a00000 -> forwardable forwarded renewable pre_authent
      Start Time: 12/6/2016 14:58:06 (local)
      End Time: 12/7/2016 0:58:04 (local)
      Renew Time: 12/13/2016 14:58:04 (local)
      Session Key Type: AES-256-CTS-HMAC-SHA1-96

#1> Client: glenk @ home.local

      Server: krbtgt/HOME.LOCAL @ HOME.LOCAL
      KerbTicket Encryption Type: AES-256-CTS-HMAC-SHA1-96
      Ticket Flags 0x40e00000 -> forwardable renewable initial pre_authent
      Start Time: 12/6/2016 14:58:04 (local)
      End Time: 12/7/2016 0:58:04 (local)
      Renew Time: 12/13/2016 14:58:04 (local)
      Session Key Type: AES-256-CTS-HMAC-SHA1-96

#2> Client: glenk @ home.local

      Server: cifs/EthicsGradient.home.local @ HOME.LOCAL
      KerbTicket Encryption Type: AES-256-CTS-HMAC-SHA1-96
      Ticket Flags 0x40a40000 -> forwardable renewable pre_authent ok_as_delegate
      Start Time: 12/6/2016 14:58:06 (local)
      End Time: 12/7/2016 0:58:04 (local)
      Renew Time: 12/13/2016 14:58:04 (local)
      Session Key Type: AES-256-CTS-HMAC-SHA1-96

#3> Client: glenk @ home.local

      Server: ldap/EthicsGradient.home.local @ HOME.LOCAL
      KerbTicket Encryption Type: AES-256-CTS-HMAC-SHA1-96
      Ticket Flags 0x40a40000 -> forwardable renewable pre_authent ok_as_delegate
      Start Time: 12/6/2016 14:58:06 (local)
      End Time: 12/7/2016 0:58:04 (local)
      Renew Time: 12/13/2016 14:58:04 (local)
      Session Key Type: AES-256-CTS-HMAC-SHA1-96

#4> Client: glenk @ home.local

      Server: LDAP/EthicsGradient.home.local/home.local @ HOME.LOCAL
      KerbTicket Encryption Type: AES-256-CTS-HMAC-SHA1-96
      Ticket Flags 0x40a40000 -> forwardable renewable pre_authent ok_as_delegate
      Start Time: 12/6/2016 14:58:06 (local)
      End Time: 12/7/2016 0:58:04 (local)
      Renew Time: 12/13/2016 14:58:04 (local)
      Session Key Type: AES-256-CTS-HMAC-SHA1-96
```

3.2 Configure client

Set up web-proxy in browser through the FortiGate. This can be achieved via a PAC file or direct browser configuration.

Some Firefox documentation indicates that it is necessary to make manual advanced configuration changes to allow Kerberos authentication work. However, builds 48 (and possibly much earlier) require no additional configuration beyond setting of the proxy server.

3.3 Open a connection to the Internet

1. The client accesses the explicit proxy, but a *HTTP 407 Proxy Authentication Required* is returned.
2. As "Negotiate" is set, the client has knowledge of the KRBTGT, it requests a ticket from the KDC with a *krb-tgs-req* message. This includes the REALM (HOME.LOCAL) in the *reg-body* section, and the provided instances SNAME and service (in this case, HTTP/artoo-deetoo.home.local).
3. The KDC responds with a next KRB-TGS-REP.

   This ticket is then available on the client.

   In the example below, the ticket-granted-service has issued Ticket #2.

```
#2>  Client: glenk @ home.local
      Server: HTTP/artoo-deetoo.home.local @ HOME.LOCAL
      KerbTicket Encryption Type: RSADSI RC4-HMAC(NT)
      Ticket Flags 0x40a00000 -> forwardable renewable pre_authent
      Start Time: 12/6/2016 14:59:45 (local)
      End Time: 12/7/2016 0:58:04 (local)
      Renew Time: 12/13/2016 14:58:04 (local)
      Session Key Type: RSADSI RC4-HMAC(NT)
```

4. The conversation between the client and the proxy continues, as the client responds with the Kerberos ticket in the response.

   The whole process takes less than a second to complete. The user should be visible as a FSSO logon in the Web UI.

Certificate authentication

You can configure certificate-based authentication for FortiGate administrators, SSL VPN users, and IPsec VPN users. See Configuring certificate-based authentication on page 626.

Certificates are also inherent to the HTTPS protocol, where the browser validates the server's identity using certificates. A site certificate must be installed on the FortiGate unit and the corresponding Certificate Authority (CA) certificate installed in the web browser.

To force the use of HTTPS, go to **User & Device > Authentication > Settings** and select **Redirect HTTP Challenge to a Secure Channel (HTTPS)**.

Restricting number of concurrent user logons

Some users on your network may often have multiple account sessions open at one time either to the same network resource or accessing to the admin interface on the FortiGate unit.

While there are valid reasons for having multiple concurrent sessions open, hackers also do this to speed up their malicious work. Often a hacker is making multiple attempts to gain access to the internal network or the admin

interface of the FortiGate unit, usually from different IP addresses to appear to the FortiGate unit as legitimate users. For this reason, the more concurrent sessions a hacker has open at once, the faster they will achieve their goal.

To help prevent this, you can disallow concurrent administrative access using the same administrator user name. This allows only one session with the same username even if it is from the same IP.

To disable concurrent administrator sessions - CLI:

```
config system global
   set admin-concurrent disable
end
```

VPN authentication

All VPN configurations require users to authenticate. Authentication based on user groups applies to:

- SSL VPNs
- PPTP and L2TP VPNs
- an IPsec VPN that authenticates users using dialup groups
- a dialup IPsec VPN that uses XAUTH authentication (Phase 1)

You must create user accounts and user groups before performing the procedures in this section. If you create a user group for dialup IPsec clients or peers that have unique peer IDs, their user accounts must be stored locally on the FortiGate unit. You cannot authenticate these types of users using a RADIUS or LDAP server.

Configuring authentication of SSL VPN users

The general procedure for authenticating SSL VPN users is:

1. Configure user accounts.
2. Create one or more user groups for SSL VPN users.
3. Enable SSL VPN.
4. Optionally, set inactivity and authentication timeouts.
5. Configure a security policy with the user groups you created for SSL VPN users.
   See FortiOS Handbook SSL VPN guide.

Configuring authentication timeout

By default, the SSL VPN authentication expires after 8 hours (28 800 seconds). You can change it only in the CLI, and the time entered must be in seconds. The maximum time is 72 hours (259 200 seconds). For example, to change this timeout to one hour, you would enter:

```
config vpn ssl settings
   set auth-timeout 3600
end
```

If you set the authentication timeout (`auth-timeout`) to 0 when you configure the timeout settings, the remote client does not have to re-authenticate unless they log out of the system. To fully take advantage of this setting, the value for `idle-timeout` has to be set to 0 also, so that the client does not time out if the maximum idle time is reached. If the `idle-timeout` is not set to the infinite value, the system will log out if it reaches the limit set, regardless of the `auth-timeout` setting.

Configuring authentication of remote IPsec VPN users

An IPsec VPN on a FortiGate unit can authenticate remote users through a dialup group. The user account name is the peer ID and the password is the pre-shared key.

Authentication through user groups is supported for groups containing only local users. To authenticate users using a RADIUS or LDAP server, you must configure XAUTH settings. See Configuring XAuth authentication.

To configure user group authentication for dialup IPsec - web-based manager:

1. Configure the dialup users who are permitted to use this VPN. Create a user group with Type:Firewall and add them to it.
   For more information, see Users and user groups on page 560
2. Go to **VPN > IPsec > Wizard**, select **Dialup**, choose a name for the VPN, and enter the following information.

Incoming Interface	Select the incoming interface name.
Authentication Method	List of authentication methods available for users. Select **Preshared Key** and enter the preshared key.
User Group	Select the user group that is to be allowed access to the VPN. The listed user groups contain only users with passwords on the FortiGate unit.

3. Select **Next** and continue configure other VPN parameters as needed.
4. Select **OK**.

To configure user group authentication for dialup IPsec - CLI example:

The `peertype` and `usrgrp` options configure user group-based authentication.

```
config vpn ipsec phase1
   edit office_vpn
      set interface port1
      set type dynamic
      set psksecret yORRAzltNGhzgtV32jend
      set proposal 3des-sha1 aes128-sha1
      set peertype dialup
      set usrgrp Group1
   end
```

Configuring XAuth authentication

Extended Authentication (XAuth) increases security by requiring additional user authentication information in a separate exchange at the end of the VPN Phase 1 negotiation. The FortiGate unit asks the user for a username and password. It then forwards the user's credentials (the password is encrypted) to an external RADIUS or LDAP server for verification.

XAuth can be used in addition to or in place of IPsec phase 1 peer options to provide access security through an LDAP or RADIUS authentication server. You must configure a dialup user group whose members are all externally authenticated.

To configure authentication for a dialup IPsec VPN - web-based manager:

1. Configure the users who are permitted to use this VPN. Create a user group and add the users to the group. For more information, see "Users and user groups" on page 560.
2. Go to **VPN > IPsec > Wizard**, select **Dialup**, choose a name for the VPN, and enter the following information.

Incoming Interface	Select the incoming interface name.
Authentication Method	List of authentication methods available for users. Select **Preshared Key** and enter the preshared key.
User Group	Select the user group that is to be allowed access to the VPN. The listed user groups contain only users with passwords on the FortiGate unit.

3. Select **Next** and continue configure other VPN parameters as needed.
4. Select **OK**.
5. Go to **VPN > IPsec > Tunnels**, edit the Tunnel just created, select **Convert To Custom Tunnel**, and edit **XAUTH** as following:

Type	Select **PAP**, **CHAP**, or **AUTO**. Use CHAP whenever possible. Use PAP with all implementations of LDAP and with other authentication servers that do not support CHAP, including some implementations of Microsoft RADIUS. Use AUTO with the Fortinet Remote VPN Client and where the authentication server supports CHAP but the XAuth client does not.
User Group	Select the user group that is to have access to the VPN. The list of user groups does not include any group that has members whose password is stored on the FortiGate unit.

6. Select **OK**.

For more information about XAUTH configuration, see the IPsec VPN chapter of the FortiOS Handbook.

To configure authentication for a dialup IPsec VPN - CLI example:

The `xauthtype` and `authusrgrp` fields configure XAuth authentication.

```
config vpn ipsec phase1
   edit office_vpn
      set interface port1
      set type dynamic
      set psksecret yORRAzltNGhzgtV32jend
      set proposal 3des-sha1 aes128-sha1
      set peertype dialup
      set xauthtype pap
      set usrgrp Group1
   end
```

Some parameters specific to setting up the VPN itself are not shown here. For detailed information about configuring IPsec VPNs, see the FortiOS Handbook IPsec VPN guide.

Configuring authentication of PPTP VPN users and user groups

Configuration of a PPTP VPN is possible only through the CLI. You can configure user groups and security policies using either CLI or web-based manager.

LDAP user authentication is supported for PPTP, L2TP, IPsec VPN, and firewall authentication.

However, with PPTP, L2TP, and IPsec VPN, PAP (Packet Authentication Protocol) is supported, while CHAP (Challenge Handshake Authentication Protocol) is not.

To configure authentication for a PPTP VPN

1. Configure the users who are permitted to use this VPN. Create a security user group and add them to it. For more information, see Users and user groups on page 560.
2. Configure the PPTP VPN in the CLI as in this example.

```
config vpn pptp
   set status enable
   set sip 192.168.0.100
   set eip 192.168.0.110
   set usrgrp PPTP_Group
end
```

The `sip` and `eip` fields define a range of virtual IP addresses assigned to PPTP clients.

Configure a security policy. The source interface is the one through which the clients will connect. The source address is the PPTP virtual IP address range. The destination interface and address depend on the network to which the clients will connect. The policy action is ACCEPT.

Configuring authentication of L2TP VPN users/user groups

Configuration of a L2TP VPN is possible only through the CLI. You can configure user groups and security policies using either CLI or web-based manager.

LDAP user authentication is supported for PPTP, L2TP, IPsec VPN, and firewall authentication.

However, with PPTP, L2TP, and IPsec VPN, PAP (Packet Authentication Protocol) is supported, while CHAP (Challenge Handshake Authentication Protocol) is not.

To configure authentication for a L2TP VPN

1. Configure the users who are permitted to use this VPN. Create a user group and add them to it. For more information, see Users and user groups on page 560.
2. Configure the L2TP VPN in the CLI as in this example.

```
config vpn l2tp
   set status enable
   set sip 192.168.0.100
   set eip 192.168.0.110
   set usrgrp L2TP_Group
end
```

The `sip` and `eip` fields define a range of virtual IP addresses assigned to L2TP clients.

3. Configure a security policy. The source interface is the one through which the clients will connect. The source address is the L2TP virtual IP address range. The destination interface and address depend on the network to which the clients will connect. The policy action is ACCEPT.

Captive portals

A captive portal is a convenient way to authenticate web users on wired or WiFi networks.

This section describes:

- Introduction to Captive portals
- Configuring a captive portal
- Customizing captive portal pages

Introduction to Captive portals

You can authenticate your users on a web page that requests the user's name and password. Until the user authenticates successfully, the authentication page is returned in response to any HTTP request. This is called a captive portal.

After successful authentication, the user accesses the requested URL and can access other web resources, as permitted by security policies. Optionally, the captive portal itself can allow web access to only the members of specified user group.

The captive portal can be hosted on the FortiGate unit or on an external authentication server. You can configure captive portal authentication on any network interface, including WiFi and VLAN interfaces.

When a captive portal is configured on a WiFi interface, the access point initially appears open. The wireless client can connect to the access point with no security credentials, but sees only the captive portal authentication page.

WiFi captive portal types:

- **Authentication** — until the user enters valid credentials, no communication beyond the AP is permitted.
- **Disclaimer + Authentication** — immediately after successful authentication, the portal presents the disclaimer page—an acceptable use policy or other legal statement—to which the user must agree before proceeding.
- **Disclaimer Only** — the portal presents the disclaimer page—an acceptable use policy or other legal statement—to which the user must agree before proceeding. The authentication page is not presented.
- **Email Collection** — the portal presents a page requesting the user's email address, for the purpose of contacting the person in future. This is often used by businesses who provide free WiFi access to their customers. The authentication page is not presented.

Configuring a captive portal

Captive portals are configured on network interfaces. On a physical (wired) network interface, you edit the interface configuration in **Network > Interfaces** and set **Security Mode** to **Captive Portal**. A WiFi interface does not exist until the WiFi SSID is created. You can configure a WiFi captive portal at the time that you create the SSID. Afterwards, the captive portal settings will also be available by editing the WiFi network interface in **Network > Interfaces**.

To configure a wired Captive Portal - web-based manager:

1. Go to **Network > Interfaces** and edit the interface to which the users connect.
2. In **Security Mode** select **Captive Portal**.

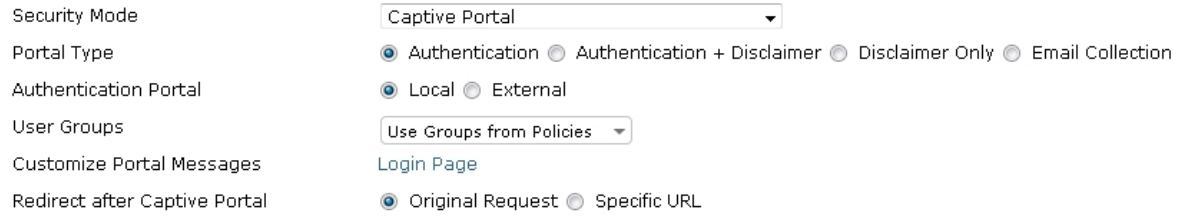
3. Enter

Authentication Portal	Local - portal hosted on the FortiGate unit. Remote - enter FQDN or IP address of external portal.
User Groups	Select permitted user groups or select **Use Groups from Policies**, which permits the groups specified in the security policy. **Use Groups from Policies** is not available in WiFi captive portals.
Exempt List	Select exempt lists whose members will not be subject to captive portal authentication.
Customize Portal Messages	Enable, then select Edit. See Customizing captive portal pages on page 608.

4. Select **OK**.

To configure a WiFi Captive Portal - web-based manager:

1. Go to **WiFi Controller > WiFi Network > SSID** and create your SSID.
   If the SSID already exists, you can edit the SSID or you can edit the WiFi interface in **Network > Interfaces**.
2. In **Security Mode**, select **Captive Portal**.



3. Enter

Portal Type	The portal can provide authentication and/or disclaimer, or perform user email address collection. See Introduction to Captive portals on page 606.
Authentication Portal	Local - portal hosted on the FortiGate unit. Remote - enter FQDN or IP address of external portal.
User Groups	Select permitted user groups.

Exempt List	Select exempt lists whose members will not be subject to captive portal authentication.
Customize Portal Messages	Click the link of the portal page that you want to modify. See "Captive portals" on page 608.

4. Select **OK**.

Exemption from the captive portal

A captive portal requires all users on the interface to authenticate. But some devices are not able to authenticate. You can create an exemption list of these devices. For example, a printer might need to access the Internet for firmware upgrades. Using the CLI, you can create an exemption list to exempt all printers from authentication.

```
config user security-exempt-list
   edit r_exempt
      config rule
         edit 1
            set devices printer
         end
      end
```

Customizing captive portal pages

These pages are defined in replacement messages. Defaults are provided. In the web-based manager, you can modify the default messages in the SSID configuration by selecting **Customize Portal Messages**. Each SSID can have its own unique portal content.

The captive portal contains the following default web pages:

- **Login page**—requests user credentials

Typical modifications for this page would be to change the logo and modify some of the text.

You can change any text that is not part of the HTML code nor a special tag enclosed in double percent (%) characters.

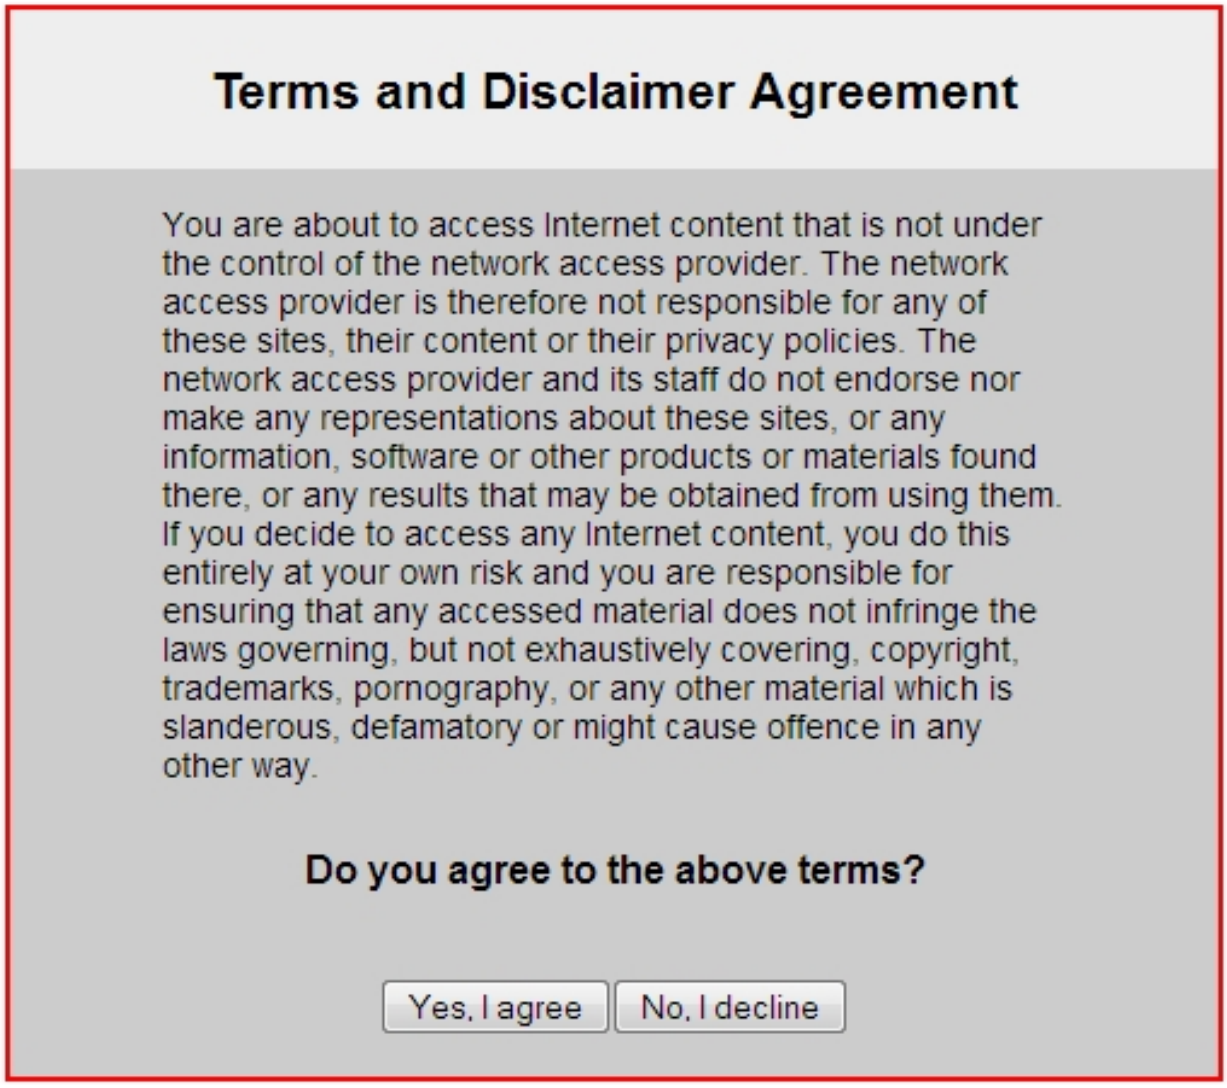
There is an exception to this rule. The line “Please enter your credentials to continue” is provided by the %%QUESTION%% tag. You can replace this tag with text of your choice. Except for this item, you should not remove any tags because they may carry information that the FortiGate unit needs.

- **Login failed page**—reports that the entered credentials were incorrect and enables the user to try again.

The Login failed page is similar to the Login page. It even contains the same login form. You can change any text that is not part of the HTML code nor a special tag enclosed in double percent (%) characters.

There is an exception to this rule. The line “Firewall authentication failed. Please try again.” is provided by the %%FAILED_MESSAGE%% tag. You can replace this tag with text of your choice. Except for this item, you should not remove any tags because they may carry information that the FortiGate unit needs.

- **Disclaimer page**—is a statement of the legal responsibilities of the user and the host organization to which the user must agree before proceeding.(WiFi or SSL VPN only)



- **Declined disclaimer page**—is displayed if the user does not agree to the statement on the Disclaimer page. Access is denied until the user agrees to the disclaimer.

Changing images in portal messages

You can replace the default Fortinet logo with your organization's logo. First, import the logo file into the FortiGate unit and then modify the Login page code to reference your file.

To import a logo file:

1. Go to **System > Replacement Messages** and select **Manage Images**.
2. Select **Create New**.
3. Enter a **Name** for the logo and select the appropriate **Content Type**.
   The file must not exceed 24 Kilo bytes.
4. Select **Browse**, find your logo file and then select **Open**.
5. Select **OK**.

To specify the new logo in the replacement message:

1. Go to **Network > Interfaces** and edit the interface.
   The **Security Mode** must be **Captive Portal**.
2. Select the portal message to edit.
   - In SSL VPN or WiFi interfaces, in **Customize Portal Messages** click the link to the portal messages that you want to edit.
   - In other interfaces, make sure that **Customize Portal Messages** is selected, select the adjacent **Edit** icon, then select the message that you want to edit.
3. In the HTML message text, find the %%IMAGE tag.
   By default it specifies the Fortinet logo: `%%IMAGE:logo_fw_auth%%`
4. Change the image name to the one you provided for your logo.
   The tag should now read, for example, `%%IMAGE:mylogo%%`
5. Select **Save**.
6. Select **OK**.

Modifying text in portal messages

Generally, you can change any text that is not part of the HTML code nor a special tag enclosed in double percent (%) characters. You should not remove any tags because they may carry information that the FortiGate unit needs. See the preceding section for any exceptions to this rule for particular pages.

To modify portal page text

1. Go to **Network > Interfaces** and edit the interface.
   The SSID **Security Mode** must be **Captive Portal**.
2. Select the portal message to edit.
   - In SSL VPN or WiFi interfaces, in **Customize Portal Messages** click the link to the portal messages that you want to edit.
   - In other interfaces, make sure that **Customize Portal Messages** is selected, select the adjacent **Edit** icon, then select the message that you want to edit.
3. Edit the HTML message text, then select **Save**.
4. Select **OK**.

Configuring disclaimer page for ethernet interface captive portals

While you can customize a disclaimer page for captive portals that connect via WiFi, the same can be done for wired connections. However, this can only be configured on the CLI Console, and only without configuring user groups.

When configuring a captive portal through the CLI, you may `set security-groups` to a specific user group. The result of this configuration will show an authentication form to users who wish to log in to the captive portal—**not** a disclaimer page. If you do not set any `security-groups` in your configuration, an "Allow all" status will be in effect, and the disclaimer page will be displayed for users.

The example CLI configuration below shows setting up a captive portal interface without setting security-groups, resulting in a disclaimer page for users:

```
config system interface
   edit "port1"
      set vdom "root"
      set ip 172.16.101.1 255.255.255.0
      set allowaccess ping https ssh snmp http
      set type physical
      set explicit-web-proxy enable
      set alias "LAN"
      set security-mode captive-portal
      set snmp-index 1
   next
end
```

Certificate-based authentication

This section provides an overview of how the FortiGate unit verifies the identities of administrators, SSL VPN users, or IPsec VPN peers using X.509 security certificates.

The following topics are included in this section:

- What is a security certificate?
- Certificates overview
- Managing X.509 certificates
- Configuring certificate-based authentication
- Support for per-VDOM certificates
- Example — Generate a CSR on the FortiGate unit
- Example — Generate and Import CA certificate with private key pair on OpenSSL
- Example — Generate an SSL certificate in OpenSSL

What is a security certificate?

A security certificate is a small text file that is part of a third-party generated public key infrastructure (PKI) to help guarantee the identity of both the user logging on and the web site they where they are logging in.

A certificate includes identifying information such as the company and location information for the web site, as well as the third-party company name, the expiry date of the certificate, and the public key.

FortiGate units use X.509 certificates to authenticate single sign-on (SSO) for users. The X.509 standard has been in use since before 2000, but has gained popularity with the Internet's increased popularity. X.509 v3 is defined in RFC 5280 and specifies standard formats for public key certificates, certificate revocation lists, and a certification path validation algorithm. The unused earlier X.509 version 1 was defined in RFC 1422.

The main difference between X.509 and PGP certificates is that where in PGP anyone can sign a certificate, for X.509 only a trusted authority can sign certificates. This limits the source of certificates to well known and trustworthy sources. Where PGP is well suited for one-to-one communications, the X.509 infrastructure is intended to be used in many different situations including one-to-many communications. Some common filename extensions for X.509 certificates are listed below.

Common certificate filename extensions

Filetype	Format name	Description
.pem	Privacy Enhanced Mail (PEM)	Base64 encoded DER certificate, that uses: "-----BEGIN CERTIFICATE-----" and "-----END CERTIFICATE-----"
.cer **.crt** **.der**	Security CERtificate	Usually binary DER form, but Base64-encoded certificates are common too.
.p7b **.p7c**		Structure without data, just certificates or CRLs. PKCS#7 is a standard for signing or encrypting (officially called "enveloping") data.
.p12	PKCS#12	May contain certificate(s) (public) and private keys (password protected).
.pfx	personal information exchange (PFX)	Older format. Came before PKCS#12. Usually today data is in PKCS#12 format.

Certificates overview

Certificates play a major role in authentication of clients connecting to network services via HTTPS, both for administrators and SSL VPN users. Certificate authentication is optional for IPsec VPN peers.

- Certificates and protocols
- IPsec VPNs and certificates
- Certificate types on the FortiGate unit

Certificates and protocols

There are a number of protocols that are commonly used with certificates including SSL and HTTPS, and other certificate-related protocols.

SSL and HTTPS

The secure HTTP (HTTPS) protocol uses SSL. Certificates are an integral part of SSL. When a web browser connects to the FortiGate unit via HTTPS, a certificate is used to verify the FortiGate unit's identity to the client. Optionally, the FortiGate unit can require the client to authenticate itself in return.

By default, the FortiGate unit uses a self-signed security certificate to authenticate itself to HTTPS clients. When the certificate is offered, the client browser displays two security messages.

- The first message prompts users to accept and optionally install the FortiGate unit's self-signed security certificate. If the user does not accept the certificate, the FortiGate unit refuses the connection. When the user accepts the certificate, the FortiGate login page is displayed, and the credentials entered by the user are encrypted before they are sent to the FortiGate unit. If the user chooses to install the certificate, the prompt is not displayed again.

- Just before the FortiGate login page is displayed, a second message informs users that the FortiGate certificate distinguished name differs from the original request. This message is displayed because the FortiGate unit redirects the connection (away from the distinguished name recorded in the self-signed certificate) and can be ignored.

Optionally, you can install an X.509 server certificate issued by a certificate authority (CA) on the FortiGate unit. You can then configure the FortiGate unit to identify itself using the server certificate instead of the self-signed certificate.

For more information, see the FortiOS Handbook SSL VPN guide.

After successful certificate authentication, communication between the client browser and the FortiGate unit is encrypted using SSL over the HTTPS link.

Certificate-related protocols

There are multiple protocols that are required for handling certificates. These include the Online Certificate Status Protocol (OCSP), Secure Certificate Enrollment Protocol (SCEP), and Server-based Certificate Validation Protocol (SCVP).

Online Certificate Status Protocol

Online Certificate Status Protocol (OCSP) allows the verification of X.509 certificate expiration dates. This is important to prevent hackers from changing the expiry date on an old certificate to a future date.

Normally certificate revocation lists (CRLs) are used, but OCSP is an alternate method available. However a CRL is a public list, and some companies may want to avoid the public exposure of their certificate structure even if it is only invalid certificates.

The OSCP check on the certificate's revocation status is typically carried out over HTTP with a request-response format. The authority responding can reply with a status of good, revoked, or unknown for the certificate in question.

Secure Certificate Enrollment Protocol

Secure Certificate Enrollment Protocol (SCEP) is an automated method of signing up for certificates. Typically this involves generating a request you send directly to the SCEP service, instead of generating a file request that may or may not be signed locally.

Server-based Certificate Validation Protocol

Server-based Certificate Validation Protocol (SCVP) is used to trace a certificate back to a valid root level certificate. This ensures that each step along the path is valid and trustworthy.

IPsec VPNs and certificates

Certificate authentication is a more secure alternative to preshared key (shared secret) authentication for IPsec VPN peers. Unlike administrators or SSL VPN users, IPsec peers use HTTP to connect to the VPN gateway configured on the FortiGate unit. The VPN gateway configuration can require certificate authentication before it permits an IPsec tunnel to be established. See Authenticating IPsec VPN users with security certificates on page 627 .

Certificate types on the FortiGate unit

There are different types of certificates available that vary depending on their intended use. FortiOS supports local, remote, CA, and CRL certificates.

Local certificates

Local certificates are issued for a specific server, or web site. Generally they are very specific, and often for an internal enterprise network. For example a personal web site for John Smith at www.example.com (such as http://www.example.com/home/jsmith) would have its own local certificate.

These can optionally be just the certificate file, or also include a private key file and PEM passphrase for added security.

For information about generating a certificate request, see Generating a certificate signing request on page 618. For information about installing a local certificate, see Obtaining and installing a signed server certificate from an external CA on page 621

Remote certificates

Remote certificates are public certificates without a private key. For dynamic certificate revocation, you need to use an Online Certificate Status Protocol (OCSP) server. The OCSP is configured in the CLI only. Installed Remote (OCSP) certificates are displayed in the Remote Certificates list. You can select **Import** to install a certificate from the management PC.

CA root certificates

CA root certificates are similar to local certificates, however they apply to a broader range of addresses or to whole company; they are one step higher up in the organizational chain. Using the local certificate example, a CA root certificate would be issued for all of www.example.com instead of just the smaller single web page.

Certificate revocation list

Certificate revocation list (CRL) is a list of certificates that have been revoked and are no longer usable. This list includes certificates that have expired, been stolen, or otherwise compromised. If your certificate is on this list, it will not be accepted. CRLs are maintained by the CA that issues the certificates and includes the date and time when the next CRL will be issued as well as a sequence number to help ensure you have the most current version of the CRL.

Certificate signing

The trust in a certificate comes from the authority that signs it. For example if VeriSign signs your CA root certificate, it is trusted by everyone. While these certificates are universally accepted, it is cumbersome and expensive to have all certificates on a corporate network signed with this level of trust.

With self-signed certificates nobody, except the other end of your communication, knows who you are and therefore they do not trust you as an authority. However this level is useful for encryption between two points — neither point may care about who signed the certificate, just that it allows both points to communicate. This is very useful for internal networks and communications.

A general rule is that CA signed certificates are accepted and sometimes required, but it is easier to self-sign certificates when you are able.

For more on the methods of certificate signing see Generating a certificate signing request on page 618.

Managing X.509 certificates

Managing security certificates is required due to the number of steps involved in both having a certificate request signed, and then distributing the correct files for use.

You use the FortiGate unit or CA software such as OpenSSL to generate a certificate request. That request is a text file that you send to the CA for verification, or alternately you use CA software to self-validate. Once validated, the certificate file is generated and must be imported to the FortiGate unit before it can be used. These steps are explained in more detail later in this section.

This section provides procedures for generating certificate requests, installing signed server certificates, and importing CA root certificates and CRLs to the FortiGate unit.

For information about how to install root certificates, CRLs, and personal or group certificates on a remote client browser, refer to your browser's documentation.

This section includes:

- Generating a certificate signing request
- Generating certificates with CA software
- Obtaining and installing a signed server certificate from an external CA
- Installing a CA root certificate and CRL to authenticate remote clients
- Troubleshooting certificates
- Online updates to certificates and CRLs
- Backing up and restoring local certificates

Generating a certificate signing request

Whether you create certificates locally with a software application or obtain them from an external certificate service, you will need to generate a certificate signing request (CSR).

When you generate a CSR, a private and public key pair is created for the FortiGate unit. The generated request includes the public key of the FortiGate unit and information such as the FortiGate unit's public static IP address, domain name, or email address. The FortiGate unit's private key remains confidential on the FortiGate unit.

After you submit the request to a CA, the CA will verify the information and register the contact information on a digital certificate that contains a serial number, an expiration date, and the public key of the CA. The CA will then sign the certificate, and you install the certificate on the FortiGate unit.

The Certificate Request Standard is a public key cryptography standard (PKCS) published by RSA, specifically PKCS10 which defines the format for CSRs. This is defined in RFC 2986.

To generate a certificate request in FortiOS - web-based manager:

1. Go to **System > Certificates > Local Certificates**.
2. Select **Generate**.
3. In the **Certificate Name** field, enter a unique meaningful name for the certificate request. Typically, this would be the hostname or serial number of the FortiGate unit or the domain of the FortiGate unit such as example.com.

Do not include spaces in the certificate name. This will ensure compatibility of a signed certificate as a PKCS12 file to be exported later on if required.

4. Enter values in the **Subject Information** area to identify the FortiGate unit:
   - If the FortiGate unit has a static IP address, select **Host IP**and enter the public IP address of the FortiGate unit. If the FortiGate unit does not have a public IP address, use an email address (or fully qualified domain name (FQDN) if available) instead.
   - If the FortiGate unit has a dynamic IP address and subscribes to a dynamic DNS service, use a FQDN if available to identify the FortiGate unit. If you select **Domain Name**, enter the FQDN of the FortiGate unit. Do not include the protocol specification (http://) or any port number or path names.

If a domain name is not available and the FortiGate unit subscribes to a dynamic DNS service, an “unable to verify certificate” type message may be displayed in the user’s browser whenever the public IP address of the FortiGate unit changes.

   - If you select **E-Mail**, enter the email address of the owner of the FortiGate unit.
5. Enter values in the **Optional Information** area to further identify the FortiGate unit.

Organization Unit	Name of your department. You can enter a series of OUs up to a maximum of 5. To add or remove an OU, use the plus (+) or minus (-) icon.
Organization	Legal name of your company or organization.
Locality (City)	Name of the city or town where the FortiGate unit is installed.
State/Province	Name of the state or province where the FortiGate unit is installed.
Country	Select the country where the FortiGate unit is installed.
e-mail	Contact email address.
Subject Alternative Name	Optionally, enter one or more alternative names for which the certificate is also valid. Separate names with a comma. A name can be: • e-mail address • IP address • URI • DNS name (alternatives to the Common Name) • directory name (alternatives to the Distinguished Name) You must precede the name with the name type. Examples: IP:1.1.1.1 email:test@fortinet.com email:my@other.address URI:http://my.url.here/

6. From the **Key Type** list, select **RSA** or **Elliptic Curve**.
7. From the **Key Size** list, select **1024 Bit**, **1536 Bit**, **2048 Bit** or **secp256r1**, **secp384r1**, **secp521r1** respectively. Larger keys are slower to generate but more secure.
8. In **Enrollment Method**, you have two methods to choose from. Select **File Based** to generate the certificate request, or **Online SCEP** to obtain a signed SCEP-based certificate automatically over the network. For the

SCEP method, enter the URL of the SCEP server from which to retrieve the CA certificate, and the CA server challenge password.

9. Select **OK**.
10. The request is generated and displayed in the **Local Certificates** list with a status of `PENDING`.
11. Select the **Download** button to download the request to the management computer.
12. In the **File Download** dialog box, select **Save** and save the Certificate Signing Request on the local file system of the management computer.
13. Name the file and save it on the local file system of the management computer.

The certificate request is ready for the certificate authority to be signed.

Generating certificates with CA software

CA software allows you to generate unmanaged certificates and CA certificates for managing other certificates locally without using an external CA service. Examples of CA software include ssl-ca from OpenSSL (available for Linux, Windows, and Mac) or gensslcert from SuSE, MS Windows Server 2000 and 2003 come with a CA as part of their certificate services, and in MS Windows 2008 CA software can be installed as part of the Active Directory installation. See Example — Generate and Import CA certificate with private key pair on OpenSSL on page 630.

The general steps for generating certificates with CA software are

1. Install the CA software as a stand-alone root CA.
2. Provide identifying information for your self-administered CA.

While following these steps, the methods vary slightly when generating server certificates, CA certificates, and PKI certificates.

Server certificate

1. Generate a Certificate Signing Request (CSR) on the FortiGate unit.
2. Copy the CSR base-64 encoded text (PKCS10 or PKCS7) into the CA software and generate the certificate. PKCS10 is the format used to send the certificate request to the signing authority. PKCS7 is the format the signing authority can use for the newly signed certificate.
3. Export the certificate as a X.509 DER encoded binary file with .CER extension
4. Upload the certificate file to the FortiGate unit Local Certificates page (type is Certificate).

CA certificate

1. Retrieve the CA Certificate from the CA software as a DER encoded file.
2. Import the CA certificate file to the FortiGate unit at **System > Certificates > Import > CA Certificates**.

PKI certificate

1. Generate a Certificate Signing Request (CSR) on the FortiGate unit.
2. Copy the CSR base-64 encoded text (PKCS#10 or PKCS#7) into the CA software and generate the certificate. PKCS10 is the format used to send the certificate request to the signing authority. PKCS7 is the format the signing authority can use for the newly signed certificate.
3. Export the certificate as a X.509 DER encoded binary file with .CER extension.
4. Install the certificate in the user's web browser or IPsec VPN client as needed.

Obtaining and installing a signed server certificate from an external CA

To obtain a signed server certificate for a FortiGate unit, you must send a request to a CA that provides digital certificates that adhere to the X.509 standard. The FortiGate unit provides a way for you to generate the request.

To submit the certificate signing request (file-based enrollment):

1. Using the web browser on the management computer, browse to the CA web site.
2. Follow the CA instructions for a base-64 encoded PKCS#10 certificate request and upload your certificate request.
3. Follow the CA instructions to download their root certificate and CRL.
   When you receive the signed server certificate from the CA, install the certificate on the FortiGate unit.

To install or import the signed server certificate - web-based manager

1. On the FortiGate unit, go to **System > Certificates > Import > Local Certificates**.
2. From **Type**, select **Local Certificate**.
3. Select **Browse**, browse to the location on the management computer where the certificate was saved, select the certificate, and then select **Open**.
4. Select **OK**, and then select **Return**.

Installing a CA root certificate and CRL to authenticate remote clients

When you apply for a signed personal or group certificate to install on remote clients, you can obtain the corresponding root certificate and CRL from the issuing CA. When you receive the signed personal or group certificate, install the signed certificate on the remote client(s) according to the browser documentation. Install the corresponding root certificate (and CRL) from the issuing CA on the FortiGate unit according to the procedures given below.

To install a CA root certificate

1. After you download the root certificate of the CA, save the certificate on the management computer. Or, you can use online SCEP to retrieve the certificate.
2. On the FortiGate unit, go to **System > Certificates > Import > CA Certificates**.
3. Do one of the following:
   - To import using SCEP, select **SCEP**. Enter the URL of the SCEP server from which to retrieve the CA certificate. Optionally, enter identifying information of the CA, such as the filename.
   - To import from a file, select **Local PC**, then select **Browse** and find the location on the management computer where the certificate has been saved. Select the certificate, and then select **Open**.
5. Select **OK**, and then select **Return**.

The system assigns a unique name to each CA certificate. The names are numbered consecutively (CA_Cert_1, CA_Cert_2, CA_Cert_3, and so on).

To import a certificate revocation list

A Certificate Revocation List (CRL) is a list of the CA certificate subscribers paired with certificate status information. The list contains the revoked certificates and the reason(s) for revocation. It also records the certificate issue dates and the CAs that issued them.

When configured to support SSL VPNs, the FortiGate unit uses the CRL to ensure that the certificates belonging to the CA and remote peers or clients are valid. The CRL has an “effective date” and a “next update” date. The

interval is typically 7 days (for Microsoft CA). FortiOS will update the CRL automatically. Also, there is a CLI command to specify an “update-interval” in seconds. Recommendation should be 24 hours (86400 seconds) but depends on company security policy.

1. After you download the CRL from the CA web site, save the CRL on the management computer.
2. Go to **System > Certificates > Import > CRL**.
3. Do one of the following:
   - To import using an HTTP server, select **HTTP** and enter the URL of the HTTP server.
   - To import using an LDAP server see this KB article.
   - To import using an SCEP server, select **SCEP** and select the Local Certificate from the list. Enter the URL of the SCEP server from which the CRL can be retrieved.
   - To import from a file, select **Local PC**, then select **Browse** and find the location on the management computer where the CRL has been saved. Select the CRL and then select **Open**.
5. Select **OK**, and then select **Return**.

Troubleshooting certificates

There are times when there are problems with certificates — a certificate is seen as expired when its not, or it can’t be found. Often the problem is with a third party web site, and not FortiOS. However, some problems can be traced back to FortiOS such as DNS or routing issues.

Certificate is reported as expired when it is not

Certificates often are issued for a set period of time such as a day or a month, depending on their intended use. This ensures everyone is using up-to-date certificates. It is also more difficult for hackers to steal and use old certificates.

Reasons a certificate may be reported as expired include:

- It really has expired based on the “best before” date in the certificate
- The FortiGate unit clock is not properly set. If the FortiGate clock is fast, it will see a certificate as expired before the expiry date is really here.
- The requesting server clock is not properly set. A valid example is if your certificate is 2 hours from expiring, a server more than two time zones away would see the certificate as expired. Otherwise, if the server’s clock is set wrongly it will also have the same effect.
- The certificate was revoked by the issuer before the expiry date. This may happen if the issuer believes a certificate was either stolen or misused. Its possible it is due to reasons on the issuer’s side, such as a system change or such. In either case it is best to contact the certificate issuer to determine what is happening and why.

A secure connection cannot be completed (Certificate cannot be found)

Everyone who uses a browser has encountered a message such as *This connection is untrusted*. Normally when you try to connect securely to a web site, that web site will present its valid certificate to prove their identity is valid. When the web site's certificate cannot be verified as valid, the message appears stating *This connection is untrusted* or something similar. If you usually connect to this web site without problems, this error could mean that someone is trying to impersonate or hijack the web site, and best practices dictates you not continue.

Reasons a web site’s certificate cannot be validated include:

- The web site uses an unrecognized self-signed certificate. These are not secure because anyone can sign them. If you accept self-signed certificates you do so at your own risk. Best practices dictate that you must confirm the ID of

the web site using some other method before you accept the certificate.

- The certificate is valid for a different domain. A certificate is valid for a specific location, domain, or sub-section of a domain such as one certificate for `support.example.com` that is not valid for `marketing.example.com`. If you encounter this problem, contact the webmaster for the web site to inform them of the problem.
- There is a DNS or routing problem. If the web site's certificate cannot be verified, it will not be accepted. Generally to be verified, your system checks with the third party certificate signing authority to verify the certificate is valid. If you cannot reach that third party due to some DNS or routing error, the certificate will not be verified.
- Firewall is blocking required ports. Ensure that any firewalls between the requesting computer and the web site allow the secure traffic through the firewall. Otherwise a hole must be opened to allow it through. This includes ports such as 443 (HTTPS) and 22 (SSH).

Online updates to certificates and CRLs

If you obtained your local or CA certificate using SCEP, you can configure online renewal of the certificate before it expires. Similarly, you can receive online updates to CRLs.

Local certificates

In the `config vpn certificate local` command, you can specify automatic certificate renewal. The relevant fields are:

`scep-url <URL_str>`	The URL of the SCEP server. This can be HTTP or HTTPS. The following options appear after you add the `<URL_str>`.
`scep-password <password_str>`	The password for the SCEP server.
`auto-regenerate-days <days_int>`	How many days before expiry the FortiGate unit requests an updated local certificate. The default is `0`, no auto-update.
`auto-regenerate-days-warning <days_int>`	How many days before local certificate expiry the FortiGate generates a warning message. The default is `0`, no warning.

In this example, an updated certificate is requested three days before it expires.

```
config vpn certificate local
   edit mycert
      set scep-url http://scep.example.com/scep
      set scep-server-password my_pass_123
      set auto-regenerate-days 3
      set auto-regenerate-days-warning 2
   end
```

CA certificates

In the `config vpn certificate ca` command, you can specify automatic certificate renewal. The relevant fields are:

Variable	Description
`scep-url <URL_str>`	The URL of the SCEP server. This can be HTTP or HTTPS.

Variable	Description
`auto-update-days <days_int>`	How many days before expiry the FortiGate unit requests an updated CA certificate. The default is `0`, no auto-update.
`auto-update-days-warning <days_int>`	How many days before CA certificate expiry the FortiGate generates a warning message. The default is `0`, no warning.

In this example, an updated certificate is requested three days before it expires.

```
config vpn certificate ca
   edit mycert
      set scep-url http://scep.example.com/scep
      set auto-update-days 3
      set auto-update-days-warning 2
   end
```

Certificate Revocation Lists

If you obtained your CRL using SCEP, you can configure online updates to the CRL using the `config vpn certificate crl` command. The relevant fields are:

Variable	Description
`http-url <http_url>`	URL of the server used for automatic CRL certificate updates. This can be HTTP or HTTPS.
`scep-cert <scep_certificate>`	Local certificate used for SCEP communication for CRL auto-update.
`scep-url <scep_url>`	URL of the SCEP CA server used for automatic CRL certificate updates. This can be HTTP or HTTPS.
`update-interval <seconds>`	How frequently, in seconds, the FortiGate unit checks for an updated CRL. Enter `0` to update the CRL only when it expires. Not available for http URLs.
`update-vdom <update_vdom>`	VDOM used to communicate with remote SCEP server for CRL auto-update.

In this example, an updated CRL is requested only when it expires.

```
config vpn certificate crl
   edit cert_crl
      set http-url http://scep.example.com/scep
      set scep-cert my-scep-cert
      set scep-url http://scep.ca.example.com/scep
      set update-interval 0
      set update-vdom root
   end
```

Backing up and restoring local certificates

The FortiGate unit provides a way to export and import a server certificate and the FortiGate unit's personal key through the CLI. If required (to restore the FortiGate unit configuration), you can import the exported file through the **System > Certificates** page of the web-based manager.

As an alternative, you can back up and restore the entire FortiGate configuration through the **System Information** widget on the Dashboard of the web-based manager. Look for **[Backup]** and **[Restore]** in the **System Configuration** row. The backup file is created in a FortiGate-proprietary format.

To export a server certificate and private key - CLI:

This procedure exports a server (local) certificate and private key together as a password protected PKCS12 file. The export file is created through a customer-supplied TFTP server. Ensure that your TFTP server is running and accessible to the FortiGate unit before you enter the command.

1. Connect to the FortiGate unit through the CLI.
2. Type the following command:

```
execute vpn certificate local export tftp <cert_name> <exp_filename> <tftp_ip>
    <password>
```

   where:

   - `<cert_name>` is the name of the server certificate; typing `?` displays a list of installed server certificates.
   - `<exp_filename>` is a name for the output file.
   - `<tftp_ip>` is the IP address assigned to the TFTP server host interface.
3. Move the output file from the TFTP server location to the management computer for future reference.

To import a server certificate and private key - web-based manager:

1. Go to **System > Certificates** and select **Import**.
2. In **Type**, select **PKCS12 Certificate**.
3. Select **Browse**. Browse to the location on the management computer where the exported file has been saved, select the file, and then select **Open**.
4. In the **Password** field, type the password needed to upload the exported file.
5. Select **OK**, and then select **Return**.

To import separate server certificate and private key files - web-based manager

Use the following procedure to import a server certificate and the associated private key file when the server certificate request and private key were not generated by the FortiGate unit. The two files to import must be available on the management computer.

1. Go to **System > Certificates** and select **Import**.
2. In **Type**, select **Certificate**.
3. Select the **Browse** button beside the **Certificate file** field. Browse to the location on the management computer where the certificate file has been saved, select the file, and then select **Open**.
4. Select the **Browse** button beside the **Key file** field. Browse to the location on the management computer where the key file has been saved, select the file, and then select **Open**.

5. If required, in the **Password** field, type the associated password, and then select **OK**.
6. Select **Return**.

Configuring certificate-based authentication

You can configure certificate-based authentication for FortiGate administrators, SSL VPN users, and IPsec VPN users.

In Microsoft Windows 7, you can use the certificate manager to keep track of all the different certificates on your local computer. To access certificate manager, in Windows 7 press the Windows key, enter “certmgr.msc” at the search prompt, and select the displayed match. Remember that in addition to these system certificates, many applications require you to register certificates with them directly.

To see FortiClient certificates, open the FortiClient Console, and select VPN. The VPN menu has options for My Certificates (local or client) and CA Certificates (root or intermediary certificate authorities). Use Import on those screens to import certificate files from other sources.

Authenticating administrators with security certificates

You can install a certificate on the management computer to support strong authentication for administrators. When a personal certificate is installed on the management computer, the FortiGate unit processes the certificate after the administrator supplies a username and password.

To enable strong administrative authentication:

- Obtain a signed personal certificate for the administrator from a CA and load the signed personal certificate into the web browser on the management computer according to the browser documentation.
- Install the root certificate and the CRL from the issuing CA on the FortiGate unit (see Installing a CA root certificate and CRL to authenticate remote clients on page 621).
- Create a PKI user account for the administrator.
- Add the PKI user account to a firewall user group dedicated to PKI-authenticated administrators.
- In the administrator account configuration, select **PKI** as the account **Type** and select the **User Group** to which the administrator belongs.

Authenticating SSL VPN users with security certificates

While the default self-signed certificates can be used for HTTPS connections, it is preferable to use the X.509 server certificate to avoid the redirection as it can be misinterpreted as possible session hijacking. However, the server certificate method is more complex than self-signed security certificates. Also the warning message is typically displayed for the initial connection, and future connections will not generate these messages.

X.509 certificates can be used to authenticate IPsec VPN peers or clients, or SSL VPN clients. When configured to authenticate a VPN peer or client, the FortiGate unit prompts the VPN peer or client to authenticate itself using the X.509 certificate. The certificate supplied by the VPN peer or client must be verifiable using the root CA certificate installed on the FortiGate unit in order for a VPN tunnel to be established.

To enable certificate authentication for an SSL VPN user group:

1. Install a signed server certificate on the FortiGate unit and install the corresponding root certificate (and CRL) from the issuing CA on the remote peer or client.
2. Obtain a signed group certificate from a CA and load the signed group certificate into the web browser used by each user. Follow the browser documentation to load the certificates.

3. Install the root certificate and the CRL from the issuing CA on the FortiGate unit (see Installing a CA root certificate and CRL to authenticate remote clients on page 621).
4. Create a PKI user for each SSL VPN user. For each user, specify the text string that appears in the Subject field of the user's certificate and then select the corresponding CA certificate.
5. Use the `config user peergrp` CLI command to create a peer user group. Add to this group all of the SSL VPN users who are authenticated by certificate.
6. Go to **Policy & Objects > Policy > IPv4**.
7. Edit the SSL-VPN security policy.
8. Select the user group created earlier in the **Source User(s)** field.
9. Select **OK**.

Authenticating IPsec VPN users with security certificates

To require VPN peers to authenticate by means of a certificate, the FortiGate unit must offer a certificate to authenticate itself to the peer.

To enable the FortiGate unit to authenticate itself with a certificate:

1. Install a signed server certificate on the FortiGate unit.
   See To install or import the signed server certificate - web-based manager on page 621.
2. Install the corresponding CA root certificate on the remote peer or client. If the remote peer is a FortiGate unit, see To install a CA root certificate on page 621.
3. Install the certificate revocation list (CRL) from the issuing CA on the remote peer or client. If the remote peer is a FortiGate unit, see To import a certificate revocation list on page 621.
4. In the VPN phase 1 configuration, set **Authentication Method** to **Signature** and from the **Certificate Name** list select the certificate that you installed in Step 1.

To authenticate a VPN peer using a certificate, you must install a signed server certificate on the peer. Then, on the FortiGate unit, the configuration depends on whether there is only one VPN peer or if this is a dialup VPN that can be multiple peers.

To configure certificate authentication of a single peer

1. Install the CA root certificate and CRL.
2. Create a PKI user to represent the peer. Specify the text string that appears in the Subject field of the user's certificate and then select the corresponding CA certificate.
3. In the VPN phase 1 **Peer Options**, select **peer certificate** for **Accept Types** field and select the PKI user that you created in the **Peer certificate** field.

To configure certificate authentication of multiple peers (dialup VPN)

1. Install the corresponding CA root certificate and CRL.
2. Create a PKI user for each remote VPN peer. For each user, specify the text string that appears in the Subject field of the user's certificate and then select the corresponding CA certificate.
3. Use the `config user peergrp` CLI command to create a peer user group. Add to this group all of the PKI users who will use the IPsec VPN.

In the VPN phase 1 **Peer Options**, select **peer certificate group** for **Accept Types** field and select the PKI user group that you created in the **Peer certificate group** field.

Support for per-VDOM certificates

The CA and local certificate configuration is available per-VDOM. When an admin uploads a certificate to a VDOM, it will only be accessible inside that VDOM. When an admin uploads a certificate to global, it will be accessible to all VDOMs and global.

There are factory default certificates such as Fortinet_CA_SSL, Fortinet_SSL, Fortinet_Wifi, and Fortinet_Factory. These certificates are moved to per-VDOM and automatically generated when a new VDOM is created.

> The Fortinet_Firmware certificate has been removed and all the attributes that use Fortinet_Firmware now use Fortinet_Factory.

CLI Changes

Two new attributes `range` and `source` have been added:

`range` can be global or per-VDOM, if the certificate file is imported from global, it is a global certificate. If the certificate file is imported from a VDOM, it is VDOM certificate.

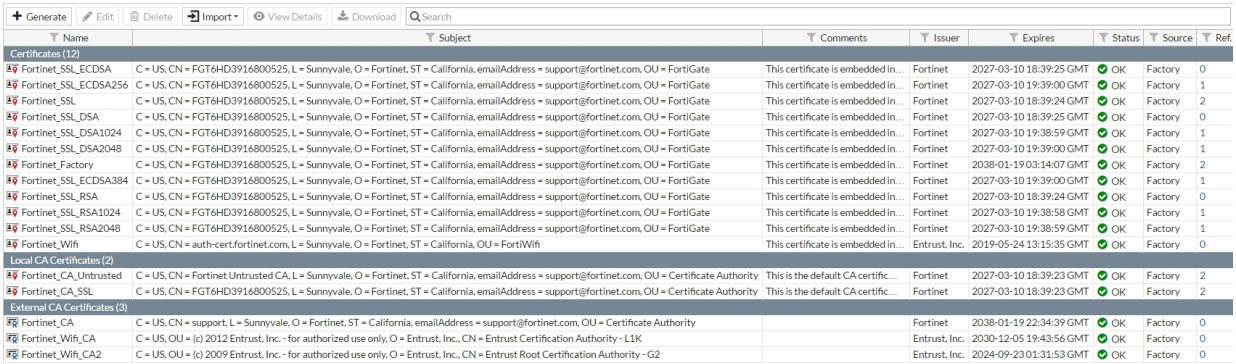
`source` can be either `factory`, `user`, or `fortiguard`:

- `factory`: The factory certificate file with FortiOS version, this includes: Fortinet_CA_SSL, Fortinet_SSL, PositiveSSL_CA, Fortinet_Wifi, Fortinet_Factory.
- `user`: Certificate file imported by the user.
- `fortiguard`: Certificate file imported from FortiGuard.

```
config certificate local
   edit Fortinet_Factory
      set range {global | vdom}
      set source {factory | user | fortiguard}
   end
end
```

GUI Changes

Global and new VDOMs have the following factory default certificates:



Name	Subject	Comments	Issuer	Expires	Status	Source	Ref.
Certificates (12)							
Fortinet_SSL_ECDSA	C = US, CN = FGT6HD3916800525, L = Sunnyvale, O = Fortinet, ST = California, emailAddress = support@fortinet.com, OU = FortiGate	This certificate is embedded in...	Fortinet	2027-03-10 18:39:25 GMT	OK	Factory	0
Fortinet_SSL_ECDSA256	C = US, CN = FGT6HD3916800525, L = Sunnyvale, O = Fortinet, ST = California, emailAddress = support@fortinet.com, OU = FortiGate	This certificate is embedded in...	Fortinet	2027-03-10 19:39:00 GMT	OK	Factory	1
Fortinet_SSL	C = US, CN = FGT6HD3916800525, L = Sunnyvale, O = Fortinet, ST = California, emailAddress = support@fortinet.com, OU = FortiGate	This certificate is embedded in...	Fortinet	2027-03-10 18:39:24 GMT	OK	Factory	2
Fortinet_SSL_DSA	C = US, CN = FGT6HD3916800525, L = Sunnyvale, O = Fortinet, ST = California, emailAddress = support@fortinet.com, OU = FortiGate	This certificate is embedded in...	Fortinet	2027-03-10 18:39:25 GMT	OK	Factory	0
Fortinet_SSL_DSA1024	C = US, CN = FGT6HD3916800525, L = Sunnyvale, O = Fortinet, ST = California, emailAddress = support@fortinet.com, OU = FortiGate	This certificate is embedded in...	Fortinet	2027-03-10 19:38:59 GMT	OK	Factory	1
Fortinet_SSL_DSA2048	C = US, CN = FGT6HD3916800525, L = Sunnyvale, O = Fortinet, ST = California, emailAddress = support@fortinet.com, OU = FortiGate	This certificate is embedded in...	Fortinet	2027-03-10 19:39:00 GMT	OK	Factory	1
Fortinet_Factory	C = US, CN = FGT6HD3916800525, L = Sunnyvale, O = Fortinet, ST = California, emailAddress = support@fortinet.com, OU = FortiGate	This certificate is embedded in...	Fortinet	2038-01-19 03:14:07 GMT	OK	Factory	2
Fortinet_SSL_ECDSA384	C = US, CN = FGT6HD3916800525, L = Sunnyvale, O = Fortinet, ST = California, emailAddress = support@fortinet.com, OU = FortiGate	This certificate is embedded in...	Fortinet	2027-03-10 19:39:00 GMT	OK	Factory	1
Fortinet_SSL_RSA	C = US, CN = FGT6HD3916800525, L = Sunnyvale, O = Fortinet, ST = California, emailAddress = support@fortinet.com, OU = FortiGate	This certificate is embedded in...	Fortinet	2027-03-10 18:39:24 GMT	OK	Factory	0
Fortinet_SSL_RSA1024	C = US, CN = FGT6HD3916800525, L = Sunnyvale, O = Fortinet, ST = California, emailAddress = support@fortinet.com, OU = FortiGate	This certificate is embedded in...	Fortinet	2027-03-10 19:38:58 GMT	OK	Factory	1
Fortinet_SSL_RSA2048	C = US, CN = FGT6HD3916800525, L = Sunnyvale, O = Fortinet, ST = California, emailAddress = support@fortinet.com, OU = FortiGate	This certificate is embedded in...	Fortinet	2027-03-10 19:38:59 GMT	OK	Factory	1
Fortinet_Wifi	C = US, CN = auth-cert.fortinet.com, L = Sunnyvale, O = Fortinet, ST = California, OU = FortiWifi	This certificate is embedded in...	Entrust, Inc.	2019-05-24 13:15:35 GMT	OK	Factory	0
Local CA Certificates (2)							
Fortinet_CA_Untrusted	C = US, CN = Fortinet Untrusted CA, L = Sunnyvale, O = Fortinet, ST = California, emailAddress = support@fortinet.com, OU = Certificate Authority	This is the default CA certific...	Fortinet	2027-03-10 18:39:23 GMT	OK	Factory	2
Fortinet_CA_SSL	C = US, CN = FGT6HD3916800525, L = Sunnyvale, O = Fortinet, ST = California, emailAddress = support@fortinet.com, OU = Certificate Authority	This is the default CA certific...	Fortinet	2027-03-10 18:39:23 GMT	OK	Factory	2
External CA Certificates (3)							
Fortinet_CA	C = US, CN = support, L = Sunnyvale, O = Fortinet, ST = California, emailAddress = support@fortinet.com, OU = Certificate Authority		Fortinet	2038-01-19 22:34:39 GMT	OK	Factory	0
Fortinet_Wifi_CA	C = US, OU = (c) 2012 Entrust, Inc. - for authorized use only, O = Entrust, Inc., CN = Entrust Certification Authority - L1K		Entrust, Inc.	2030-12-05 19:43:56 GMT	OK	Factory	0
Fortinet_Wifi_CA2	C = US, OU = (c) 2009 Entrust, Inc. - for authorized use only, O = Entrust, Inc., CN = Entrust Root Certification Authority - G2		Entrust, Inc.	2024-09-23 01:31:53 GMT	OK	Factory	0

These certificates are created automatically when a new VDOM is created, with every VDOM having its own versions of these certificates.

Example — Generate a CSR on the FortiGate unit

This example follows all the steps required to create and install a local certificate on the FortiGate unit, without using CA software.

The FortiGate unit is called myFortiGate60, and is located at 10.11.101.101 (a private IP address) and http://myfortigate.example.com. Mr. John Smith (john.smith@myfortigate.example.com) is the IT administrator for this FortiGate unit, and the unit belongs to the Sales department located in Greenwich, London, England.

To generate a certificate request on the FortiGate unit - web-based manager:

1. Go to **System > Certificates**.
2. Select **Generate**.
3. In the **Certificate Name** field, enter `myFortiGate60`.

Do not include spaces in the certificate name. This will ensure compatibility of a signed certificate as a PKCS12 file to be exported later on if required.

Since the IP address is private, we will use the FQDN instead.

4. Select **Domain Name**, and enter `http://myfortigate.example.com`.
5. Enter values in the **Optional Information** area to further identify the FortiGate unit.

Organization Unit	Sales
Organization	Example.com
Locality (City)	Greenwich
State/Province	London
Country	England
e-mail	john.smith@myfortigate.example.com

6. From the **Key Type** list, select **RSA** or **Elliptic Curve**.
7. If RSA is selected, from the **Key Size** list, select **2048 Bit**. If Elliptic Curve is selected,from the **Curve Name** list, select **secp256r1**.
8. In **Enrollment Method**, select **File Based** to generate the certificate request
9. Select **OK**.
   The request is generated and displayed in the **Local Certificates** list with a status of PENDING.
10. Select the **Download** button to download the request to the management computer.
11. In the **File Download** dialog box, select ***Save*** and save the Certificate Signing Request on the local file system of the management computer.
12. Name the file and save it on the local file system of the management computer.

Example — Generate and Import CA certificate with private key pair on OpenSSL

This example explains how to generate a certificate using OpenSSL on MS Windows. OpenSSL is available for Linux and Mac OS as well, however their terminology will vary slightly from what is presented here.

Assumptions

Before starting this procedure, ensure that you have downloaded and installed OpenSSL on Windows. One source is: http://www.slproweb.com/products/Win32OpenSSL.html.

Generating and importing the CA certificate and private key

The two following procedures will generate a CA certificate file and private key file, and then import it to the FortiGate unit as a local certificate.

To generate the private key and certificate

1. At the Windows command prompt, go to the OpenSSL bin directory. If you installed to the default location this will be the command:

   ```
   cd c:\OpenSSL-Win32\bin
   ```

2. Enter the following command to generate the private key. You will be prompted to enter your PEM pass phrase. Choose something easy to remember such as fortinet123.

   ```
   openssl genrsa -aes256 -out fgtcapriv.key 2048
   ```

   This command generates an RSA AES256 2048-bit encryption key.

3. The following command will generate the certificate using the key from the previous step.

   ```
   openssl req -new -x509 -days 3650 -extensions v3_ca -key fgtcapriv.key -out
       fgtca.crt
   ```

   This step generates an X509 CA certificate good for 10 years that uses the key generated in the previous step. The certificate filename is `fgtca.crt`.

   You will be prompted to enter information such as PEM Pass Phrase from the previous step, Country Name, State, Organization Name, Organizational Unit (such as department name), Common Name (the FQDN), and Email Address.

To import the certificate to the FortiGate unit - web-based manager:

1. Go to **System > Certificates**.
2. Select **Import > Local Certificate**.
3. Select **Certificate** for **Type**.
   Fields for Certificate file, Key file, and Password are displayed.
4. For **Certificate file**, enter `c:\OpenSSL-Win32\bin\fgtca.crt`.
5. For **Key file**, enter `c:\OpenSSL-Win32\bin\fgtcapriv.key`.
6. For **Password**, enter the PEM Pass Phrase you entered earlier, such as fortinet123.
7. Select **OK**.

The Certificate will be added to the list of Local Certificates and be ready for use. It will appear in the list as the filename you uploaded — `fgtca`.You can add comments to this certificate to make it clear where its from and how it is intended to be used. If you download the certificate from FortiOS, it is a .CER file.

It can now be used in Authenticating IPsec VPN users with security certificates on page 627, and Authenticating SSL VPN users with security certificates on page 626.

Example — Generate an SSL certificate in OpenSSL

This example explains how to generate a CA signed SSL certificate using OpenSSL on MS Windows. OpenSSL is available for Linux and Mac OS as well, however their terminology will vary slightly from what is presented here.

In this example, you will:

- Generate a CA signed SSL certificate
- Generate a self-signed SSL certificate
- Import the SSL certificate into FortiOS

Assumptions

- Before starting this procedure, ensure that you have downloaded and installed OpenSSL on MS Windows. One download source is http://www.slproweb.com/products/Win32OpenSSL.html.

Generating a CA signed SSL certificate

This procedure assumes that you have already completed Example — Generate and Import CA certificate with private key pair on OpenSSL on page 630 successfully.

To generate the CA signed SSL certificate:

1. At the Windows command prompt, go to the OpenSSL bin directory. If you installed to the default location this will be the following command:

   ```
   cd c:\OpenSSL-Win32\bin
   ```

2. Enter the following command to generate the private key. You will be prompted to enter your PEM pass phrase. Choose something easy to remember such as fortinet.

   ```
   openssl genrsa -aes256 -out fgtssl.key 2048
   ```

   This command generates an RSA AES256 2048-bit encryption key.

3. Create a certificate signing request for the SSL certificate. This step requires you to enter the information listed in step 3 of the previous example — To generate the private key and certificate. You can leave the Challenge Password blank.

   ```
   openssl req -new -sha256 -key fgtssl.key -out fgtssl.csr
   ```

Most Certificate Authorities will ignore the value that is set in the CSR and use whatever value they are set to use in their configuration. This means that the client will likely need to modify their openssl.conf file to use SHA-256 (or another SHA-2 variant).

4. Using the CSR from the previous step, you can now create the SSL certificate using the CA certificate that was created in Example — Generate and Import CA certificate with private key pair on OpenSSL.

```
openssl x509 -req -days 365 -in fgtssl.csr -CA fgtca.crt -CAkey fgtcapriv.key -set_
    serial 01 -out fgtssl.crt
```

This will generate an X.509 certificate good for 365 days signed by the CA certificate fgtca.crt.

Generating a self-signed SSL certificate

This procedures does not require any existing certificates.

1. At the Windows command prompt, go to the OpenSSL bin directory. If you installed to the default location this will be the following command:

```
cd c:\OpenSSL-Win32\bin
```

2. Enter the following command to generate the private key. You will be prompted to enter your PEM pass phrase. Choose something easy to remember such as fortinet.

```
openssl genrsa -aes256 -out fgtssl.key 2048
openssl req -new -key fgtssl.key -out fgtssl.csr
openssl x509 -req -days 365 -in fgtssl.csr -signkey fgtssl.key -out fgtssl.crt
```

These commands:

- generate an RSA AES256 2048-bit private key,
- generate an SSL certificate signing request, and
- sign the CSR to generate an SSL .CRT certificate file.

Import the SSL certificate into FortiOS

To import the certificate to FortiOS- web-based manager

1. Go to **System > Certificates**.
2. Select **Import > Local Certificate**.
3. Select **Certificate** for **Type**.
   Fields for Certificate file, Key file, and Password are displayed.
4. For **Certificate file**, enter `c:\OpenSSL-Win32\bin\fgtssl.crt`.
5. For **Key file**, enter `c:\OpenSSL-Win32\bin\fgtssl.key`.
6. For **Password**, enter the PEM Pass Phrase you entered, such as fortinet.
7. Select **OK**.

The SSL certificate you just uploaded can be found under **System > Certificates** under the name of the file you uploaded — `fgtssl`.

To confirm the certificate is uploaded properly - CLI:

```
config vpn certificate local
   edit fgtssl
      get
   end
```

The get command will display all the certificate's information. If it is not there or the information is not correct, you will need to remove the corrupted certificate (if it is there) and upload it again from your PC.

To use the new SSL certificate - CLI

```
config vpn ssl settings
   set servercert fgtssl
end
```

This assigns the fgtssl certificate as the SSL server certificate. For more information see the FortiOS Handbook SSL VPN guide.

Single Sign-On using a FortiAuthenticator unit

If you use a FortiAuthenticator unit in your network as a single sign-on agent,

- Users can authenticate through a web portal on the FortiAuthenticator unit.
- Users with FortiClient Endpoint Security installed can be automatically authenticated by the FortiAuthenticator unit through the FortiClient SSO Mobility Agent.

The FortiAuthenticator unit can integrate with external network authentication systems such as RADIUS and LDAP to gather user logon information and send it to the FortiGate unit.

User's view of FortiAuthenticator SSO authentication

There are two different ways users can authenticate through a FortiAuthenticator unit.

Users without FortiClient Endpoint Security - SSO widget

To log onto the network, the user accesses the organization's web page with a web browser. Embedded on that page is a simple logon widget, like this:

	User not logged in. Click **Login** to go to the FortiAuthenticator login page.
	User logged in. Name displayed. **Logout** button available.

The SSO widget sets a cookie on the user's browser. When the user browses to a page containing the login widget, the FortiAuthenticator unit recognizes the user and updates its database if the user's IP address has changed. The user will not need to re-authenticate until the login timeout expires, which can be up to 30 days.

Users with FortiClient Endpoint Security - FortiClient SSO Mobility Agent

The user simply accesses resources and all authentication is performed transparently with no request for credentials. IP address changes, such as those due to WiFi roaming, are automatically sent to the FortiAuthenticator unit. When the user logs off or otherwise disconnects from the network, the FortiAuthenticator unit is aware of this and deauthenticates the user.

The FortiClient SSO Mobility Agent, a feature of FortiClient Endpoint Security v5.0, must be configured to communicate with the appropriate FortiAuthenticator unit. After that, the agent automatically provides user name and IP address information to the FortiAuthenticator unit for transparent authentication.

Administrator's view of FortiAuthenticator SSO authentication

You can configure either or both of these authentication types on your network.

SSO widget

You need to configure the Single Sign-On portal on the FortiAuthenticator unit. Go to **Fortinet SSO Methods > SSO > Portal Services** to do this. Copy the **Embeddable login widget** code for use on your organization's

home page. Identity-based security policies on the FortiGate unit determine which users or groups of users can access which network resources.

FortiClient SSO Mobility Agent

Your users must be running at least FortiClient Endpoint Security v5.0 to make use of this type of authentication.

On the FortiAuthenticator unit, you need to select **Enable FortiClient SSO Mobility Agent Service**, optionally select **Enable Authentication** and choose a **Secret key**. Go to **Fortinet SSO Methods > SSO > General**. You need to provide your users the FortiAuthenticator IP address and secret key so that they can configure the FortiClient SSO Mobility Agent on their computers. See Configuring the FortiGate unit on page 636.

Configuring the FortiAuthenticator unit

The FortiAuthenticator unit can poll FortiGate units, Windows Active Directory, RADIUS servers, LDAP servers, and FortiClients for information about user logon activity.

To configure FortiAuthenticator polling:

1. Go to **Fortinet SSO Methods > SSO > General**.
2. In the **FortiGate** section, leave the Listening port at 8000, unless your network requires you to change this. The FortiGate unit must allow traffic on this port to pass through the firewall.
   Optionally, you can set the Login Expiry time. This is the length of time users can remain logged in before the system logs them off automatically. The default is 480 minutes (8 hours).
3. Select **Enable Authentication** and enter the **Secret key**. Be sure to use the same secret key when configuring the FSSO Agent on FortiGate units.
4. In the **Fortinet Single Sign-On (FSSO)** section, enter

Enable Windows Active Directory domain controllers	Select for integration with Windows Active Directory.
Enable Radius accounting SSO clients	Select if you want to use a Remote Radius server.
Enable Syslog SSO	Select for integration with Syslog server.
Enable FortiClient SSO Mobility Agent service **Enable Authentication**	Select both options to enable single sign-on by clients running FortiClient Endpoint Security. Enter the **Secret key**. Be sure to use the same secret key in the FortiClient Single Sign-On Mobility Agent settings.

5. Select **OK**.

For more information, see the FortiAuthenticator Administration Guide.

Configuring the FortiGate unit

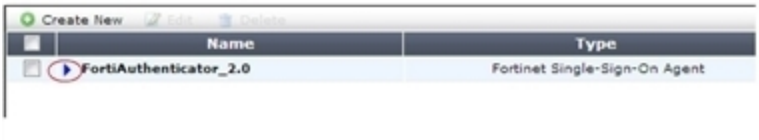
Adding a FortiAuthenticator unit as an SSO agent

On the FortiGate unit, you need to add the FortiAuthenticator unit as a Single Sign-On agent that provides user logon information.

To add a FortiAuthenticator unit as SSO agent:

1. Go to **User & Device > Authentication > Single Sign-On** and select **Create New**.
2. In **Type**, select **Fortinet Single-Sign-On Agent**.
3. Enter a **Name** for the FortiAuthenticator unit.
4. In Primary Agent IP/Name, enter the IP address of the FortiAuthenticator unit.
5. In Password, enter the secret key that you defined for the FortiAuthenticator unit.
   On the FortiAuthenticator unit, you go to **Fortinet SSO Methods > SSO > General** to define the secret key.
   Select **Enable Authentication**.
6. Select **OK**.

In a few minutes, the FortiGate unit receives a list of user groups from the FortiAuthenticator unit. The entry in the Single Sign-On server list shows a blue caret.



When you open the server, you can see the list of groups. You can use the groups in identity-based security policies.

Configuring an FSSO user group

You cannot use FortiAuthenticator SSO user groups directly in a security policy. Create an FSSO user group and add FortiAuthenticator SSO user groups to it. FortiGate FSSO user groups are available for selection in identity-based security policies.

To create an FSSO user group:

1. Go to **User & Device > User > User Groups** and select **Create New**.
2. Enter a **Name** for the group.
3. In Type, select **Fortinet Single Sign-On (FSSO)**.
4. Add **Members**.
   The groups available to add as members are SSO groups provided by SSO agents.
5. Select **OK**.

Configuring security policies

You can create identity-based policies based on FSSO groups as you do for local user groups. For more information about security policies see the Firewall chapter.

Configuring the FortiClient SSO Mobility Agent

The user's device must have at least FortiClient Endpoint Security v5.0 installed. Only two pieces of information are required to set up the SSO Mobility Agent feature: the FortiAuthenticator unit IP address and the preshared secret.

The user needs to know the FortiAuthenticator IP address and preshared secret to set up the SSO Mobility Agent. Or, you could preconfigure FortiClient.

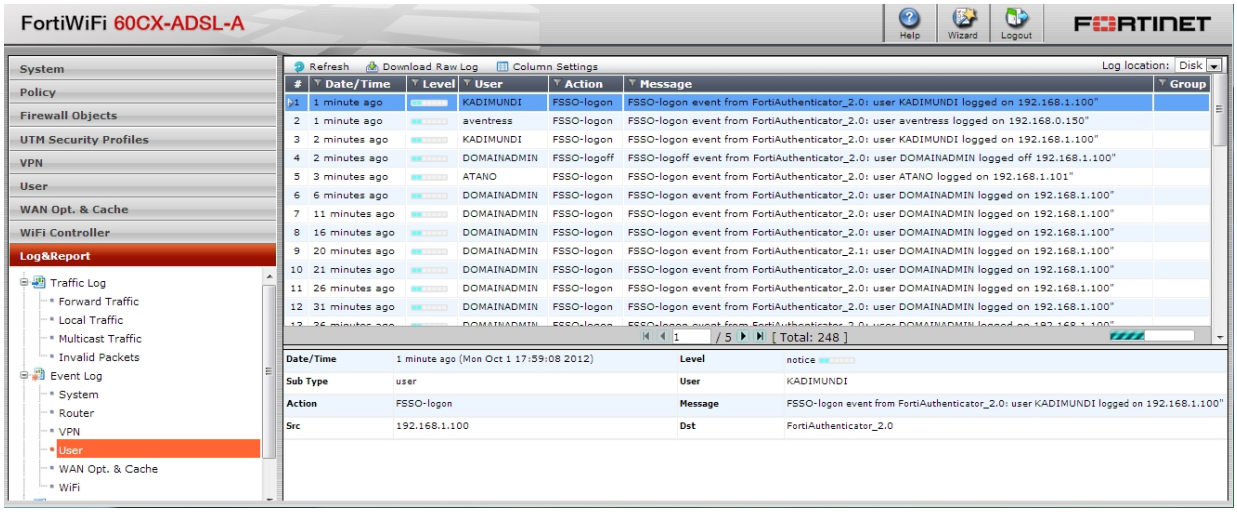
To configure FortiClient SSO Mobility Agent:

1. In FortiClient Endpoint Security, go to **File > Settings**.
   You must run the FortiClient application as an administrator to access these settings.
2. Select **Enable single sign-on mobility agent**. Enter the FortiAuthenticator unit IP address, including the listening port number specified on the FortiAuthenticator unit.
   Example: 192.168.0.99:8001. You can omit the port number if it is 8005.
3. Enter the preshared key.
4. Select **OK**.

Viewing SSO authentication events on the FortiGate unit

User authentication events are logged in the FortiGate event log.

Go to **Log & Report > Event Log > User**.



Single Sign-On to Windows AD

The FortiGate unit can authenticate users transparently and allow them network access based on their privileges in Windows AD. This means that users who have logged on to the network are not asked again for their credentials to access network resources through the FortiGate unit, hence the term “Single Sign-On”.

The following topics are included:

- Introduction to Single Sign-On with Windows AD
- Configuring Single Sign On to Windows AD
- FortiOS FSSO log messages
- Testing FSSO
- Troubleshooting FSSO

Introduction to Single Sign-On with Windows AD

Introduced in FortiOS 5.0, Single Sign-On (SSO) support provided by FortiGate polling of domain controllers is simpler than the earlier method that relies on agent software installed on Windows AD network servers. No Fortinet software needs to be installed on the Windows network. The FortiGate unit needs access only to the Windows AD global catalog and event log.

When a Windows AD user logs on at a workstation in a monitored domain, the FortiGate unit

- detects the logon event in the domain controller’s event log and records the workstation name, domain, and user,
- resolves the workstation name to an IP address,
- uses the domain controller’s LDAP server to determine which groups the user belongs to,
- creates one or more log entries on the FortiGate unit for this logon event as appropriate.

When the user tries to access network resources, the FortiGate unit selects the appropriate security policy for the destination. The selection consist of matching the FSSO group or groups the user belongs to with the security policy or policies that match that group. If the user belongs to one of the permitted user groups associated with that policy, the connection is allowed. Otherwise the connection is denied.

Configuring Single Sign On to Windows AD

On the FortiGate unit, security policies control access to network resources based on user groups. With Fortinet Single Sign On, this is also true but each FortiGate user group is associated with one or more Windows AD user groups. This is how Windows AD user groups get authenticated in the FortiGate security policy.

Fortinet Single Sign On sends information about Windows user logons to FortiGate units. If there are many users on your Windows AD domains, the large amount of information might affect the performance of the FortiGate unit.

To configure your FortiGate unit to operate with either a Windows AD or a Novell eDirectory FSSO install, you

- Configure LDAP access to the Windows AD global catalog. See Configuring LDAP server access on page 639.
- Configure the LDAP Server as a Single Sign-On server. See Configuring the LDAP Server as a Single Sign-On server on page 640.

- Add Active Directory user groups to FortiGate FSSO user groups. See Creating Fortinet Single Sign-On (FSSO) user groups on page 641.
- Create security policies for FSSO-authenticated groups. See Creating security policies on page 641.
- Optionally, specify a guest protection profile to allow guest access. See Enabling guest access through FSSO security policies on page 643

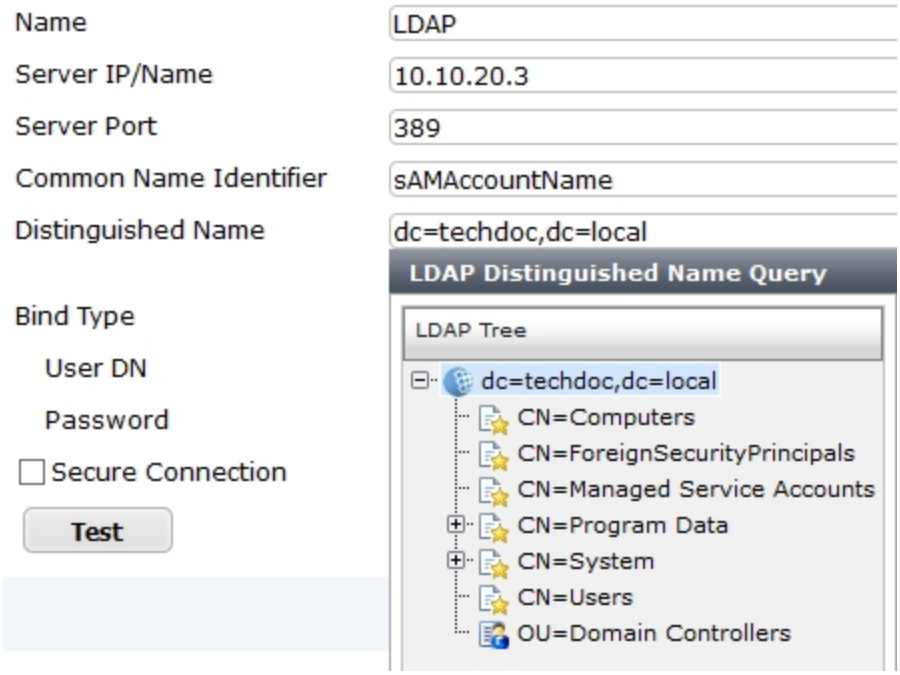
Configuring LDAP server access

The FortiGate unit needs access to the domain controller's LDAP server to retrieve user group information.

The LDAP configuration on the FortiGate unit not only provides access to the LDAP server, it sets up the retrieval of Windows AD user groups for you to select in FSSO. The LDAP Server configuration (in **User & Device > Authentication > LDAP Servers**) includes a function to preview the LDAP server's response to your distinguished name query. If you already know the appropriate Distinguished Name (DN) and User DN settings, you may be able to skip some of the following steps.

To add an LDAP server - web-based manager:

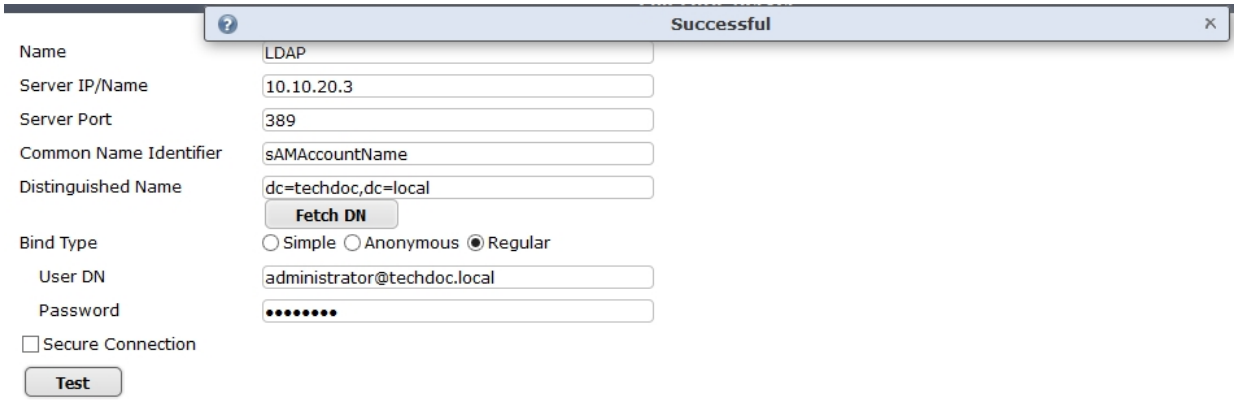
1. Go to **User & Device > Authentication > LDAP Servers** and select **Create New**.
2. Enter the **Server IP/Name** and **Server Port** (default 389).
3. In the **Common Name Identifier** field, enter **sAMAccountName**.The default common name identifier is `cn`. This is correct for most LDAP servers. However some servers use other identifiers such as `uid`.
4. In the **Distinguished Name** field, enter your organization distinguished name. In this example, Distinguished Name is dc=techdoc,dc=local
5. Select **Fetch DN**, this will fetch the Windows AD directory.



6. Set **Bind Type** to **Regular.**
7. In the **User DN** field, enter the administrative account name that you created for FSSO.
   For example, if the account is administrator, enter "administrator@techdoc.local".

8. Enter the administrative account password in the **Password** field.
9. Optionally select **Secure Connection**.
   - In the **Protocol** field, select **LDAPS** or **STARTTLS**.
   - In the **Certificate** field, select the appropriate certificate for authentication.

   Note that you need to configure the Windows AD for secure connection accordingly.
10. Select **OK**.
11. Test your configuration by selecting the **Test** button. A successful message confirming the right settings appears.



To configure LDAP for FSSO - CLI example:

```
config user ldap
   edit LDAP
      set server 10.10.20.3
      set cnid sAMAccountName
      set dn dc=techdoc,dc=local
      set type regular
      set username administrator@techdoc.local
      set password <your_password>
   next
end
```

Configuring the LDAP Server as a Single Sign-On server

The LDAP server must be added to the FortiGate Single Sign-On configuration.

To add the LDAP server as a Single Sign-On server:

1. Go to **User & Device > Authentication > Single Sign-On** and select **Create New**.
2. Enter

Type	Poll Active Directory Server
Server IP/Name	Server Name or IP address of the Domain Controller
User	A Domain user name
Password	The user's password

LDAP Server	Select the LDAP server you added earlier.
Enable Polling	Select

3. Select **OK**.

Creating Fortinet Single Sign-On (FSSO) user groups

You cannot use Windows or Novell groups directly in FortiGate security policies. You must create FortiGate user groups of the FSSO type and add Windows or Novell groups to them.

To create a user group for FSSO authentication - web-based manager:

1. Go to **User & Device > User > User Groups** and select **Create New**.
   The **New User Group** dialog box opens.
2. In the **Name** box, enter a name for the group, FSSO_Internet_users for example.
3. In **Type**, select **Fortinet Single Sign-On (FSSO)**.
4. In **Members**, select the required **FSSO** groups.
5. Select **OK**.

To create the FSSO_Internet-users user group - CLI

```
config user group
   edit FSSO_Internet_users
      set group-type fsso-service
      set member CN=Engineering,cn=users,dc=office,dc=example,dc=com
          CN=Sales,cn=users,dc=office,dc=example,dc=com
   end
```

Default FSSO group

`SSO_Guest_users` is a default user group enabled when FSSO is configured. It allows guest users on the network who do not have an FSSO account to authenticate and have access to network resources. See Enabling guest access through FSSO security policies on page 643.

Creating security policies

Policies that require FSSO authentication are very similar to other security policies. Using identity-based policies, you can configure access that depends on the FSSO user group. This allows each FSSO user group to have its own level of access to its own group of services

In this situation, Example.com is a company that has its employees and authentication servers on an internal network. The FortiGate unit intercepts all traffic leaving the internal network and requires FSSO authentication to access network resources on the Internet. The following procedure configures the security policy for FSSO authentication. FSSO is installed and configured including the RADIUS server, FSSO Collector agent, and user groups on the FortiGate

For the following procedure, the internal interface is `port1` and the external interface connected to the Internet is `port2`. There is an address group for the internal network called `company_network`. The FSSO user group is called `fsso_group`, and the FSSO RADIUS server is `fsso_rad_server`.

To configure an FSSO authentication security policy - web-based manager:

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter the following information.

Incoming Interface	port1
Source Address	company_network
Source User(s)	`fsso_group`
Outgoing Interface	port2
Destination Address	all
Schedule	always
Service	HTTP, HTTPS, FTP, and Telnet
Action	ACCEPT
NAT	ON
UTM Security Profiles	ON for AntiVirus, IPS, Web Filter, and Email Filter, all using default profiles.
Log Allowed Traffic	ON. Select **Security Events**.

3. Select **OK**.
4. Ensure the FSSO authentication policy is higher in the policy list than more general policies for the same interfaces.

To create a security policy for FSSO authentication - CLI:

```
config firewall policy
   edit 0
      set srcintf port1
      set dstintf port2
      set srcaddr company_network
      set dstaddr all
      set action accept
      set groups fsso_group
      set schedule always
      set service HTTP HTTPS FTP TELNET
      set nat enable
   end
```

Here is an example of how this FSSO authentication policy is used. Example.com employee on the internal company network logs on to the internal network using their RADIUS username and password. When that user attempts to access the Internet, which requires FSSO authentication, the FortiGate authentication security policy intercepts the session, checks with the FSSO Collector agent to verify the user's identity and credentials, and then if everything is verified the user is allowed access to the Internet.

Enabling guest access through FSSO security policies

You can enable guest users to access FSSO security policies. Guests are users who are unknown to Windows AD and servers that do not logon to a Windows AD domain.

To enable guest access in your FSSO security policy, add an identity-based policy assigned to the built-in user group `SSO_Guest_Users`. Specify the services, schedule and UTM profiles that apply to guest users — typically guests have access to a reduced set of services. See Creating security policies on page 641.

FortiOS FSSO log messages

There are two types of FortiOS log messages — firewall and event. FSSO related log messages are generated from authentication events. These include user logon and log off events, and NTLM authentication events. These log messages are central to network accounting policies, and can also be useful in troubleshooting issues. For more information on firewall logging, see Enabling security logging on page 593. For more information on logging, see the FortiOS Handbook Logging and Reporting guide.

Enabling authentication event logging

For the FortiGate unit to log events, that specific type of event must be enabled under logging.

When VDOMs are enabled certain options may not be available, such as CPU and memory usage events. You can enable event logs only when you are logged on to a VDOM; you cannot enable event logs globally.

To ensure you log all the events needed, set the minimum log level to Notification or Information. Firewall logging requires Notification as a minimum. The closer to Debug level, the more information will be logged.

To enable event logging:

1. Go to **Log&Report > Log Config > Log Settings**.
2. In **Event Logging**, select

System activity event	All system-related events, such as ping server failure and gateway status.
User activity event	All administration events, such as user logins, resets, and configuration updates.

3. Select **Apply**.

List of FSSO related log messages

Message ID	Severity	Description
43008	Notification	Authentication was successful
43009	Notification	Authentication session failed
43010	Warning	Authentication locked out
43011	Notification	Authentication timed out
43012	Notification	FSSO authentication was successful

Message ID	Severity	Description
43013	Notification	FSSO authentication failed
43014	Notification	FSSO user logged on
43015	Notification	FSSO user logged off
43016	Notification	NTLM authentication was successful
43017	Notification	NTLM authentication failed

For more information on logging, see the FortiOS Handbook Logging and Reporting guide.

Testing FSSO

Once FSSO is configured, you can easily test to ensure your configuration is working as expected. For additional FSSO testing, see Troubleshooting FSSO on page 644.

1. Logon to one of the stations on the FSSO domain, and access an Internet resource.
2. Connect to the CLI of the FortiGate unit, and if possible log the output.
3. Enter the following command:`diagnose debug authd fsso list`
4. Check the output. If FSSO is functioning properly you will see something similar to the following:

```
----FSSO logons----
IP: 192.168.1.230 User: ADMINISTRATOR Groups: VLAD-AD/DOMAIN USERS
IP: 192.168.1.240 User: ADMINISTRATOR Groups: VLAD-AD/DOMAIN USERS
Total number of users logged on: 2
----end of FSSO logons----
```

   The exact information will vary based on your installation.

5. Check the FortiGate event log, for FSSO-auth action or other FSSO related events with FSSO information in the message field.
6. To check server connectivity, run the following commands from the CLI:

```
FGT# diagnose debug enable
FGT# diagnose debug authd fsso server-status
FGT# Server Name Connection Status
     ----------- -----------------
     SBS-2003 connected
```

Troubleshooting FSSO

When installing, configuring, and working with FSSO some problems are quite common. A selection of these problems follows including explanations and solutions.

Some common Windows AD problems include:

- General troubleshooting tips for FSSO
- Users on a particular computer (IP address) can not access the network
- Guest users do not have access to network

General troubleshooting tips for FSSO

The following tips are useful in many FSSO troubleshooting situations.

- Ensure all firewalls are allowing the FSSO required ports through.
  FSSO has a number of required ports that must be allowed through all firewalls or connections will fail. These include: ports 139, 389 (LDAP), 445, 636 (LDAP).
- Ensure there is at least 64kbps bandwidth between the FortiGate unit and domain controllers. If there is insufficient bandwidth, some FSSO information might not reach the FortiGate unit. The best solution is to configure traffic shaping between the FortiGate unit and the domain controllers to ensure that the minimum bandwidth is always available.

Users on a particular computer (IP address) can not access the network

Windows AD Domain Controller agent gets the username and workstation where the logon attempt is coming from. If there are two computers with the same IP address and the same user trying to logon, it is possible for the authentication system to become confused and believe that the user on computer_1 is actually trying to access computer_2.

Windows AD does not track when a user logs out. It is possible that a user logs out on one computer, and immediate logs onto a second computer while the system still believes the user is logged on the original computer. While this is allowed, information that is intended for the session on one computer may mistakenly end up going to the other computer instead. The result would look similar to a hijacked session.

Solutions

- Ensure each computer has separate IP addresses.
- Encourage users to logout on one machine before logging onto another machine.
- If multiple users have the same username, change the usernames to be unique.
- Shorten timeout timer to flush inactive sessions after a shorter time.

Guest users do not have access to network

A group of guest users was created, but they don’t have access.

Solution

The group of the guest users was not included in a policy, so they do not fall under the guest account. To give them access, associate their group with a security policy.

Additionally, there is a default group called `SSO_Guest_Users`. Ensure that group is part of an identity-based security policy to allow traffic.

Agent-based FSSO

FortiOS can provide single sign-on capabilities to Windows AD, Citrix, VMware Horizon, Novell eDirectory, or, as of FortiOS 5.4, Microsoft Exchange users with the help of agent software installed on these networks. The agent software sends information about user logons to the FortiGate unit. With user information such as IP address and user group memberships from the network, FortiGate security policies can allow authenticated network access to users who belong to the appropriate user groups without requesting their credentials again.

For Windows AD networks, FortiGate units can provide SSO capability without agent software by directly polling the Windows AD domain controllers. For information about this type of SSO, seeSingle Sign-On to Windows AD on page 638.

The following topics are included:

- Introduction to agent-based FSSO
- FSSO NTLM authentication support
- Agent installation
- Configuring the FSSO Collector agent for Windows AD
- Configuring the FSSO TS agent for Citrix
- Configuring FSSO with Novell networks
- Configuring FSSO Advanced Settings
- Configuring FSSO on FortiGate units
- FortiOS FSSO log messages
- Testing FSSO
- Troubleshooting FSSO

Introduction to agent-based FSSO

Fortinet Single Sign-On (FSSO), through agents installed on the network, monitors user logons and passes that information to the FortiGate unit. When a user logs on at a workstation in a monitored domain, FSSO

- detects the logon event and records the workstation name, domain, and user,
- resolves the workstation name to an IP address,
- determines which user groups the user belongs to,
- sends the user logon information, including IP address and groups list, to the FortiGate unit
- creates one or more log entries on the FortiGate unit for this logon event as appropriate.

When the user tries to access network resources, the FortiGate unit selects the appropriate security policy for the destination. If the user belongs to one of the permitted user groups associated with that policy, the connection is allowed. Otherwise the connection is denied.

FSSO can also provide NTLM authentication service for requests coming from FortiGate. SSO is very convenient for users, but may not be supported across all platforms. NTLM is not as convenient, but it enjoys wider support. See FSSO NTLM authentication support on page 652.

Introduction to FSSO agents

There are several different FSSO agents that can be used in an FSSO implementation:

- Domain Controller (DC) agent
- eDirectory agent
- Citrix/Terminal Server (TS) agent
- Collector (CA) agent

Consult the latest FortiOS and FSSO Release Notes for operating system compatibility information.

Domain Controller (DC) agent

The Domain Controller (DC) agent must be installed on every domain controller if you will use DC Agent mode, but is not required if you use Polling mode. See FSSO for Windows AD on page 648.

eDirectory agent

The eDirectory agent is installed on a Novell network to monitor user logons and send the required information to the FortiGate unit. It functions much like the Collector agent on a Windows AD domain controller.The agent can obtain information from the Novell eDirectory using either the Novell API or LDAP.

Citrix/Terminal Server (TS) agent

The Citrix/Terminal Server (TS) agent is installed on a Citrix or VMware Horizon 7.4 terminal server to monitor user logons in real time. It functions much like the DC Agent on a Windows AD domain controller.

Collector (CA) agent

This agent is installed as a service on a server in the Windows AD network to monitor user logons and send the required information to the FortiGate unit. The Collector agent can collect information from

- Domain Controller agent (Windows AD)
- TS agent (Citrix or VMware Horizon Terminal Server)

In a Windows AD network, the Collector agent can optionally obtain logon information by polling the AD domain controllers. In this case, DC agents are not needed.

The Collector can obtain user group information from the DC agent or optionally, a FortiGate unit can obtain group information directly from AD using Lightweight Directory Access Protocol (LDAP).

On a Windows AD network, the FSSO software can also serve NT LAN Manager (NTLM) requests coming from client browsers (forwarded by the FortiGate unit) with only one or more Collector agents installed. See FSSO NTLM authentication support on page 652.

The CA is responsible for DNS lookups, group verification, workstation checks, and as mentioned FortiGate updates of logon records. The FSSO Collector Agent sends Domain Local Security Group and Global Security Group information to FortiGate units. The CA communicates with the FortiGate over TCP port 8000 and it listens on UDP port 8002 for updates from the DC agents.

The FortiGate unit can have up to five CAs configured for redundancy. If the first on the list is unreachable, the next is attempted, and so on down the list until one is contacted. See Configuring FSSO on FortiGate units on page 680.

All DC agents must point to the correct Collector agent port number and IP address on domains with multiple DCs.

A FortiAuthenticator unit can act much like a Collector agent, collecting Windows AD user logon information and sending it to the FortiGate unit. It is particularly useful in large installations with several FortiGate units. For more information, see the FortiAuthenticator Administration Guide.

FSSO for Microsoft Exchange Server

As of FortiOS 5.4, FSSO supports monitoring Microsoft Exchange Server. This is useful for situations when the user accesses the domain account to view their email, even when the client device might not be in the domain.

Support for the Exchange server is configured on the Back-end FSSO collector agent. For more information on the collector agent, see Collector agent installation:

1. On the FSSO collector agent, go to **Advanced Settings > Exchange Server**.
2. Select **Add** and enter the following information and select **OK**:

Domain Name	Enter your domain name.
Server IP/Hostname	Enter the IP address or the hostname of your exchange server.
Polling forwarded event log	This option for scenarios when you do not want that CA polls the Exchange Server logs directly. In this case you need to configure event log forwarding on the Exchange server. Exchange event logs can be forwarded to any member server. If you enable this, instead of the IP of the Exchange server configured in the previous step, you must then configure the IP of this member server. CA will then contact the member server.
Ignore Name	Because CA will also check Windows log files for logon events and when a user authenticates to Exchange Server there is also a logon event in Windows event log, which CA will read and this will overwrite the Exchange Server logon event (ESEventLog) on CA. So it is recommended to set the ignore list to the domain the user belongs to. To do so, enter the domain name in the **Ignore Name** field and select **Add**.

FSSO for Windows AD

FSSO for Windows AD requires at least one Collector agent. Domain Controller agents may also be required depending on the Collector agent working mode. There are two working modes to monitor user logon activity: DC Agent mode or Polling mode.

Collector agent DC Agent mode versus Polling mode

	DC Agent mode	Polling Mode
Installation	Complex — Multiple installations: one agent per DC plus Collector agent, requires a reboot	Easy — Only Collector agent installation, no reboot required

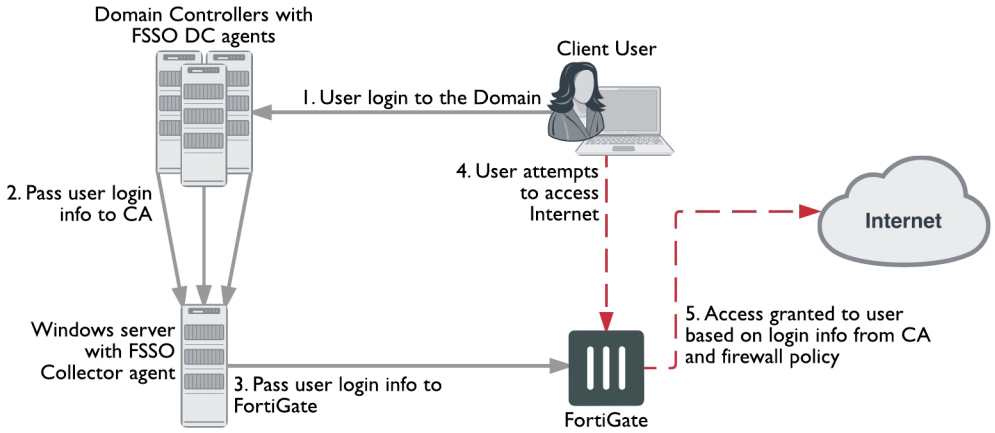
	DC Agent mode	Polling Mode
Resources	Shares resources with DC system	Has own resources
Network load	Each DC agent requires minimum 64kpbs bandwidth, adding to network load	Increase polling period during busy period to reduce network load
Level of Confidence	Captures all logons	Potential to miss a login if polling period is too great

DC Agent mode

DC Agent mode is the standard mode for FSSO. In DC Agent mode, a Fortinet authentication agent is installed on each domain controller. These DC agents monitor user logon events and pass the information to the Collector agent, which stores the information and sends it to the FortiGate unit.

The DC agent installed on the domain controllers is not a service like the Collector agent — it is a DLL file called `dcagent.dll` and is installed in the `Windows\system32` directory. It must be installed on all domain controllers of the domains that are being monitored.

FSSO in DC agent mode



DC Agent mode provides reliable user logon information, however you must install a DC agent on every domain controller. A reboot is needed after the agent is installed. Each installation requires some maintenance as well. For these reasons it may not be possible to use the DC Agent mode.

Each domain controller connection needs a minimum guaranteed 64kpbs bandwidth to ensure proper FSSO functionality. You can optionally configure traffic shapers on the FortiGate unit to ensure this minimum bandwidth is guaranteed for the domain controller connections.

Polling mode

In Polling mode there are three options — NetAPI polling, Event log polling, and Event log using WMI. All share the advantages of being transparent and agentless.

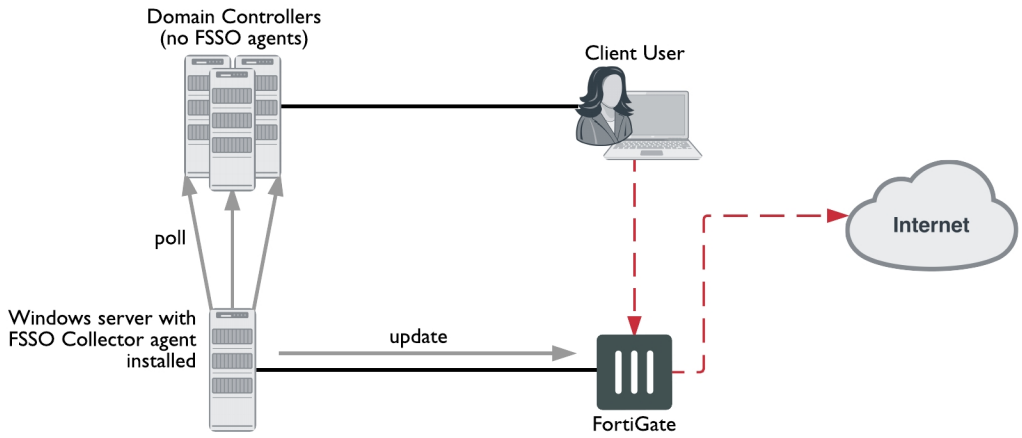
NetAPI polling is used to retrieve server logon sessions. This includes the logon event information for the Controller agent. NetAPI runs faster than Event log polling but it may miss some user logon events under heavy system load. It requires a query round trip time of less than 10 seconds.

Event log polling may run a bit slower, but will not miss events, even when the installation site has many users that require authentication. It does not have the 10 second limit on NetAPI polling. Event log polling requires fast network links. Event log polling is required if there are Mac OS users logging into Windows AD.

Event log using WMI polling: WMI is a Windows API to get system information from a Windows server, CA is a WMI client and sends WMI queries for user logon events to DC, which in this case is a WMI server. Main advantage in this mode is that CA does not need to search security event logs on DC for user logon events, instead, DC returns all requested logon events via WMI. This also reduces network load between CA and DC.

In Polling mode, the Collector agent polls port 445 of each domain controller for user logon information every few seconds and forwards it to the FortiGate unit. There are no DC Agents installed, so the Collector agent polls the domain controllers directly.

FSSO in Polling mode



A major benefit of Polling mode is that no FSSO DC Agents are required. If it is not possible to install FSSO DC Agents on your domain controllers, this is the alternate configuration available to you. Polling mode results in a less complex install, and reduces ongoing maintenance. The minimum permissions required in Polling mode are to read the event log or call NetAPI.

Collector agent AD Access mode - Standard versus Advanced

The Collector agent has two ways to access Active Directory user information. The main difference between Standard and Advanced mode is the naming convention used when referring to username information.

Standard mode uses regular Windows convention: Domain\Username. Advanced mode uses LDAP convention: CN=User, OU=Name, DC=Domain.

If there is no special requirement to use LDAP— best practices suggest you set up FSSO in Standard mode. This mode is easier to set up, and is usually easier to maintain and troubleshoot.

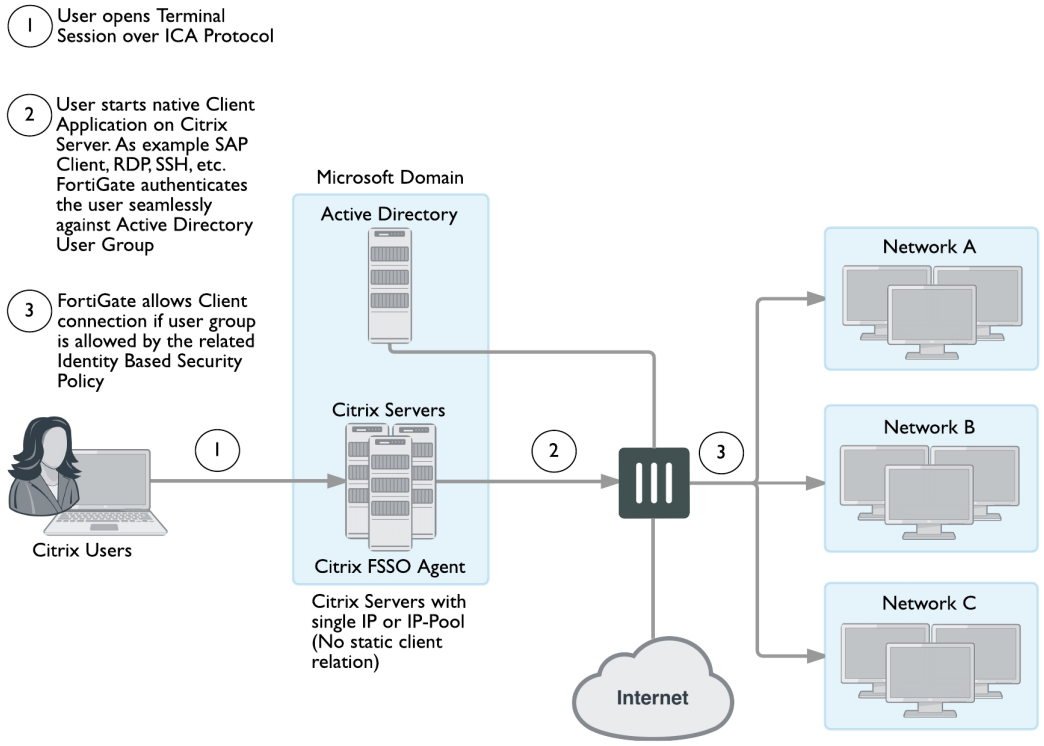
Standard and advanced modes have the same level of functionality with the following exceptions:

- Users have to create Group filters on the Collector agent. This differs from Advanced mode where Group filters are configured from the FortiGate unit. Fortinet strongly encourages users to create filters from CA.
- Advanced mode supports nested or inherited groups. This means that users may be a member of multiple monitored groups. Standard mode does not support nested groups so a user must be a direct member of the group being monitored.

FSSO for Citrix

Citrix users can enjoy a similar Single Sign-On experience as Windows AD users. The FSSO TS agent installed on each Citrix server provides user logon information to the FSSO Collector agent on the network. The FortiGate unit uses this information to authenticate the user in security policies.

Citrix SSO topology



Citrix users do not have unique IP addresses. When a Citrix user logs on, the TS agent assigns that user a range of ports. By default each user has a range of 200 ports.

FSSO for Novell eDirectory

FSSO in a Novell eDirectory environment works similar to the FSSO Polling mode in the Windows AD environment. The eDirectory agent polls the eDirectory servers for user logon information and forwards the information to the FortiGate unit. There is no need for the Collector agent.

When a user logs on at a workstation, FSSO:

- detects the logon event by polling the eDirectory server and records the IP address and user ID,
- looks up in the eDirectory which groups this user belongs to,
- sends the IP address and user groups information to the FortiGate unit.

When the user tries to access network resources, the FortiGate unit selects the appropriate security policy for the destination. If the user belongs to one of the permitted user groups, the connection is allowed.

FSSO is supported on the Novell E-Directory 8.8 operating system.

For a Novell network, there is only one FSSO component to install — the eDirectory agent. In some cases, you also need to install the Novell Client.

FSSO security issues

When the different components of FSSO are communicating there are some inherent security features.

FSSO installation requires an account with network admin privileges. The security inherent in these types of accounts helps ensure access to FSSO configurations is not tampered with.

User passwords are never sent between FSSO components. The information that is sent is information to identify a user including the username, group or groups, and IP address.

NTLM uses base-64 encoded packets, and uses a unique randomly generated challenge nonce to avoid sending user information and password between the client and the server.

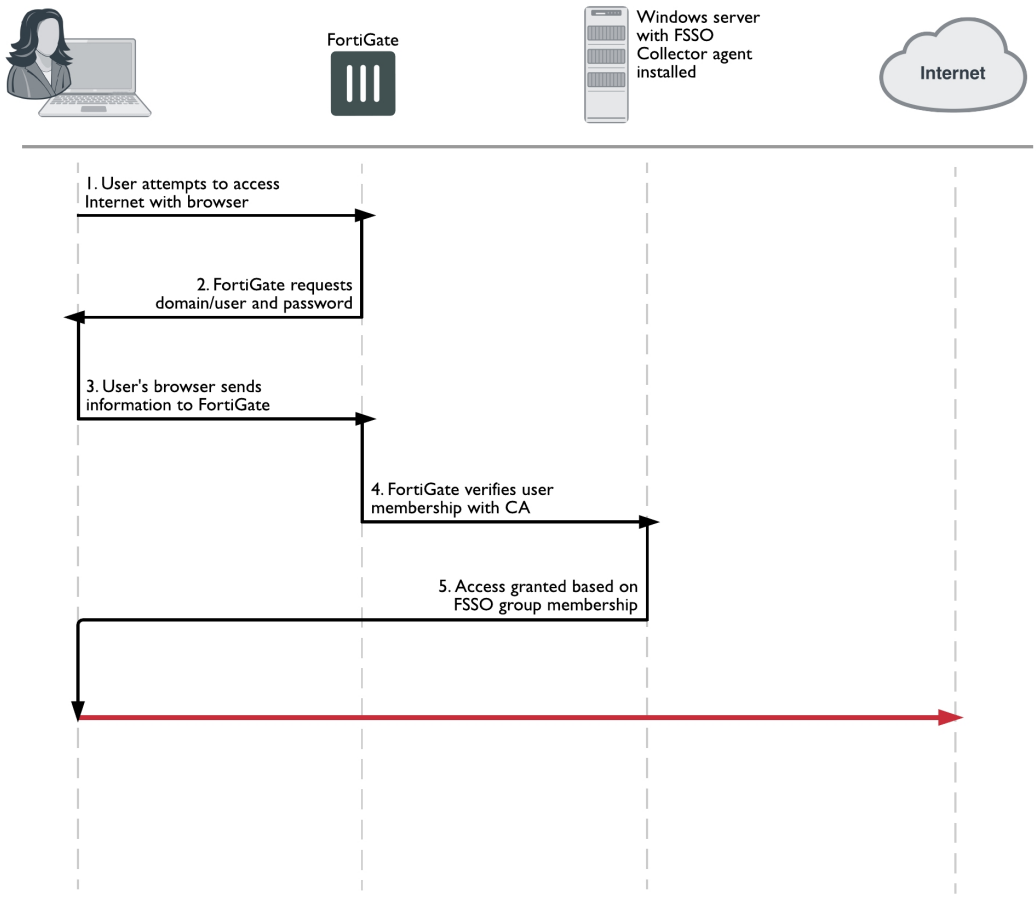
FSSO NTLM authentication support

In a Windows AD network, FSSO can also provide NTLM authentication service to the FortiGate unit. When the user makes a request that requires authentication, the FortiGate unit initiates NTLM negotiation with the client browser. The FortiGate unit does not process the NTLM packets itself. Instead, it forwards all the NTLM packets to the FSSO service to process.

NTLM has the benefit of not requiring an FSSO agent, but it is not transparent to users, and the user's web browser must support NTLM.

The NTLM protocol protects the user's password by not sending it over the network. Instead, the server sends the client a random number that the client must encrypt with the hash value of the user's password. The server compares the result of the client's encryption with the result of its own encryption. The two will match only if both parties used the same password.

NTLM authentication



If the NTLM authentication with the Windows AD network is successful, and the user belongs to one of the groups permitted in the applicable security policy, the FortiGate unit allows the connection but will require authentication again in the future when the current authentication expires.

Fortinet has tested NTLM authentication with Internet Explorer and Firefox browsers.

NTLM in a multiple domain environment

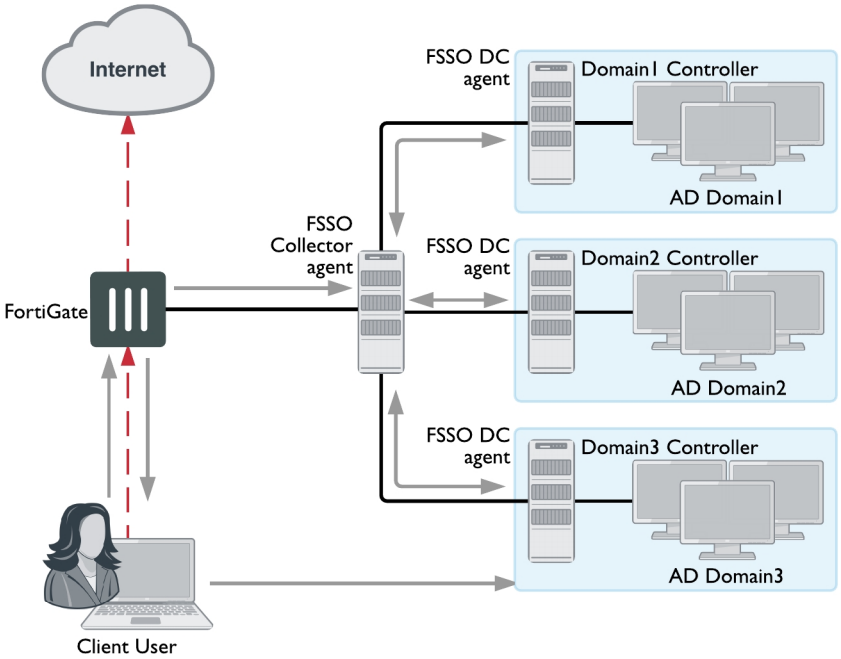
In a multiple domain environment for NTLM, the important factor is that there is a trust relation between the domains. In a forest, this relation is automatically created. So you can install FSSO agent on one of the domain controllers without worry.

But in case of multiple domains that are not in a forest, you need to create a trust relation between the domains. If you do not want to have a trust relation between your multiple domains, you need to use FSAE 4.0 MR1 and the DC agent needs to be installed once on each domain. Then you can use security policies to configure server access.

In the figure below, three domains are shown connected to the FSSO Collector agent server. The Client logs on to their local Domain Controller, which then sends the user logon event information to the Collector Agent. When the Client attempts to access the Internet, the FortiGate unit contacts the Collector Agent for the logon information, sees the Client is authenticated, and allows access to the Internet. There are multiple domains each

with a domain controller agent (DCagent) that sends logon information to the Collector agent. If the multiple domains have a trust relationship, only one DCagent is required instead of one per domain.

FSSO NTLM with multiple domains not in a forest



Understanding the NTLM authentication process

1. The user attempts to connect to an external (internet) HTTP resource. The client application (browser) on the user's computer issues an unauthenticated request through the FortiGate unit.
2. The FortiGate is aware that this client has not authenticated previously, so responds with a `401 Unauthenticated` status code, and tells the client which authentication method to reply with in the header: `Proxy-Authenticated: NTLM`. Then the initial session is dismantled.
3. The client application connects again to the FortiGate, and issues a GET-request, with a `Proxy-Authorization: NTLM <negotiate string>` header. `<negotiate-string>` is a base64-encoded NTLM Type 1 negotiation packet.
4. The FortiGate unit replies with a `401 "proxy auth required"` status code, and a `Proxy-Authenticate: NTLM <challenge string>` (a base 64-encoded NTLM Type 2 challenge packet). In this packet is the challenge nonce, a random number chosen for this negotiation that is used once and prevents replay attacks.

The TCP connection must be kept alive, as all subsequent authentication-related information is tied to the TCP connection. If it is dropped, the authentication process must start again from the beginning.

5. The client sends a new GET-request with a header: `Proxy-Authenticate: NTLM <authenticate string>`, where `<authenticate string>` is a NTLM Type 3 Authentication packet that contains:

- username and domain
- the challenge nonce encoded with the client password (it may contain the challenge nonce twice using different algorithms).

6. If the negotiation is successful and the user belongs to one of the groups permitted in the security policy, the connection is allowed, Otherwise, the FortiGate unit denies the authentication by issuing a 401 return code and prompts for a username and password. Unless the TCP connection is broken, no further credentials are sent from the client to the proxy.

If the authentication policy reaches the authentication timeout period, a new NTLM handshake occurs.

Agentless NTLM support

Agentless NTLM authentication can be configured directly from the FortiGate to the Domain Controller via SMB protocol (no agent is required).

Note that this authentication method is only supported for proxy policies.

Syntax

Note that `domain-controller` is only available when `method` is set to `ntlm` and/or `negotiate-ntlm` is set to `enable`.

```
config authentication scheme
   edit <name>
      set method ntlm
      set domain-controller <dc-setting>
   next
end

config user domain-controller
   edit <name>
      set ip-address <dc-ip>
      set port <port> - default = 445
      set domain-name <dns-name>
      set ldap-server <name>
   next
end
```

Agent installation

After reading the appropriate sections of Introduction to agent-based FSSO on page 646 to determine which FSSO agents you need, you can proceed to perform the necessary installations.

Ensure you have administrative rights on the servers where you are installing FSSO agents. It is best practice to install FSSO agents using the built-in local administrator account. Optionally, you can install FSSO without an admin account. See Installing FSSO without using an administrator account on page 658.

In Windows 2008 by default, you do not have administrative user rights if you are logged on as a user other than as the built-in administrator, even if you were added to the local Administrators group on the computer.

The FSSO installer first installs the Collector agent. You can then continue with installation of the DC agent, or you can install it later by going to **Start > Programs > Fortinet > Fortinet Single Sign On Agent > Install DC Agent**. The installer will install a DC agent on the domain controllers of all of the trusted domains in your network.

Each domain controller connection needs a minimum guaranteed 64kpbs bandwidth to ensure proper FSSO functionality.Traffic shapers configured on the FortiGate can help guarantee these minimum bandwidths.

Collector agent installation

To install FSSO, you must obtain the FSSO_Setup file from the Fortinet Support web site. This is available as either an executable (.exe) or a Microsoft Installer (.msi) file. Then you follow these two installation procedures on the server that will run the Collector agent. This can be any server or domain controller that is part of your network. These procedures also installs the DC Agent on all of the domain controllers in your network.

IPv6 source addresses can be configured for connecting to an FSSO agent.

To install the Collector agent:

1. Create an account with administrator privileges and a password that does not expire. See Microsoft Advanced Server documentation for help with this task.
   To use a non-admin read only account, see Installing FSSO without using an administrator account on page 658.
2. Log on to the account that you created in Step 1.
3. Double-click the `FSSOSetup.exe` file.
   The Fortinet SSO Collector Agent Setup Wizard starts.
4. Select **Next**.
5. Read and accept the license agreement. Select **Next**.
6. Optionally, you can change the installation location. Select **Next**.
7. Optionally, change the **User Name**.
8. By default, the agent is installed using the currently running account. If you want FSSO to use another existing admin account, change the **User Name** using the format DomainName \ UserName. For example if the account is `jsmith` and the domain is **example_corp** you would enter `example_corp\jsmith`.
9. In the **Password** field, enter the password for the account listed in the **User Name** field.
10. Select **Next**.
11. Enable as needed:
    - Monitor user logon events and send the information to the FortiGate unit
    - Serve NTLM authentication requests coming from FortiGate
      By default, both methods are enabled. You can change these options after installation.
12. Select the access method to use for Windows Directory:
13. Select **Standard** to use Windows domain and username credentials.
14. Select **Advanced** if you will set up LDAP access to Windows Directory.
    See Collector agent AD Access mode - Standard versus Advanced on page 650.

15. Select **Next** and then select **Install**.
    If you want to use DC Agent mode, ensure that **Launch DC Agent Install Wizard** is selected. This will start DC agent installation immediately after you select **Finish**.
16. Select **Finish**.

If you see an error such as Service Fortinet Single Sign On agent (service_FSAE) failed to start, there are two possible reasons for this. Verify the user account you selected has sufficient privileges to run the FSSO service. Also verify the computer system you are attempting to install on is a supported operating system and version.

DC agent installation

The FSSO_Setup file contains both the Collector agent and DC Agent installers, but the DC Agent installer is also available separately as either a .exe or .msi file named DCAgent_Setup.

To install the DC Agent

1. If you have just installed the Collector agent, the FSSO - Install DC Agent wizard starts automatically. Otherwise, go to **Start > Programs > Fortinet > Fortinet Single Sign On Agent > Install DC Agent**.
2. Select **Next**.
3. Read and accept the license agreement. Select **Next**.
4. Optionally, you can change the installation location. Select **Next**.
5. Enter the **Collector agent IP address**.
6. If the Collector agent computer has multiple network interfaces, ensure that the one that is listed is on your network. The listed **Collector agent listening port** is the default. Only change this if the port is already used by another service.
7. Select **Next**.
8. Select the domains to monitor and select **Next**.
9. If any of your required domains are not listed, cancel the wizard and set up the proper trusted relationship with the domain controller. Then run the wizard again by going to **Start > Programs > Fortinet > Fortinet Single Sign On Agent > Install DC Agent**.
10. Optionally, select users that you do not want monitored. These users will not be able to authenticate to FortiGate units using FSSO. You can also do this later. See Configuring the FSSO Collector agent for Windows AD on page 660.
11. Select **Next**.
12. Optionally, clear the check boxes of domain controllers on which you do not want to install the DC Agent.
13. Select the **Working Mode** as DC Agent Mode. While you can select Polling Mode here, in that situation you would not be installing a DC Agent. For more information, see DC Agent mode on page 649 and Polling mode on page 649.
14. Select **Next**.
15. Select **Yes** when the wizard requests that you reboot the computer.

If you reinstall the FSSO software on this computer, your FSSO configuration is replaced with default settings.

If you want to create a redundant configuration, repeat the Collector agent installation procedure on at least one other Windows AD server.

When you start to install a second Collector agent, cancel the Install Wizard dialog appears the second time. From the configuration GUI, the monitored domain controller list will show your domain controllers un-selected. Select the ones you wish to monitor with this Collector agent, and select **Apply**.

Before you can use FSSO, you need to configure it on both Windows AD and on the FortiGate units. Configuring FSSO on FortiGate units on page 680 will help you accomplish these two tasks.

Installing FSSO without using an administrator account

Normally when installing services in Windows, it is best to use the Domain Admin account, as stated earlier. This ensures installation goes smoothly and uninterrupted, and when using the FSSO agent there will be no permissions issues. However, it is possible to install FSSO with a non-admin account in Windows 2003 or 2008 AD.

The following instructions for Windows 2003 are specific to the event log polling mode only. Do not use this procedure with other FSSO configurations.

Windows 2003

There are two methods in Windows 2003 AD for installing FSSO without an admin account — add the non-admin user to the security log list, and use a non-admin account with read-only permissions. A problem with the first method is that full rights (read, write, and clear) are provided to the event log. This can be a problem when audits require limited or no write access to logs. In those situations, the non-admin account with read-only permissions is the solution.

To add the non-admin user account to the Windows 2003 security log list :

1. Go to **Default Domain Controller Security Settings > Security Settings > User Rights Assignment > Manage auditing and security log**.
2. Add the user account to this list.
3. Repeat these steps on every domain controller in Windows 2003 AD.
   A reboot is required.

To use a non-admin account with read-only permissions to install FSSO on Windows 2003:

The following procedure provides the user account specified with read only access to the Windows 2003 AD Domain Controller Security Event Log which allows FSSO to function.

1. Find out the SID of the account you intend to use.
   Tools for this can be downloaded for free from http://technet.microsoft.com/en-us/sysinternals/bb897417.
2. Then create the permission string. For example:
   - `(A;;0x1;;;S-1-5-21-4136056096-764329382-1249792191-1107)`
   - `A` means Allow,

- `0x1` means Read, and
- `S-1-5-21-4136056096-764329382-1249792191-1107` is the SID.

3. Then, append it to the registry key:
`HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\Eventlog\Security\CustomSD`
4. Repeat these steps on every domain controller in Windows 2003 AD.
A reboot is required.

Windows 2008

In Windows 2008 AD, if you do not want to use the Domain Admin account then the user account that starts the FSSO agent needs to be added to the Event Log Readers group.

When the user is added to the Event Log Readers group, that user is now allowed to have read only access to the event log and this is the minimal rights required for FSSO to work.

Citrix TS agent installation

To install the Citrix TS agent, you must obtain the TSAgent_Setup file from the Fortinet Support web site. Perform the following installation procedure on the Citrix server.

To install the FSSO TS agent:

1. On the Citrix server, create an account with administrator privileges and a password that does not expire. See Citrix documentation for more information.
2. Log on to the account that you created in step 1.
3. Double-click the TSAgent_Setup installation file.
The Fortinet SSO Terminal Server Agent Setup Wizard starts.
4. Select **Next**.
5. Read and accept the license agreement. Select **Next**.
6. Optionally, you can change the installation location. Select **Next**.
7. Verify that **This Host IP Address** is correct.
8. In the **FSSO Collector Agent List**, enter the IP address(es) of your Collector Agents.
9. Select **Next** and then select **Install**.
The TS agent is installed.
10. Select **Finish**.

Novell eDirectory agent installation

To install the eDirectory agent, you must obtain the FSSO_Setup_eDirectory file from the Fortinet Support web site. Perform the following installation procedure on the computer that will run the eDirectory agent. This can be any server or domain controller that is part of your network. You will need to provide some setup information.

To install the FSSO eDirectory agent:

1. Create an account with administrator privileges and a password that does not expire. See Novell documentation for more information.
2. Log on to the account that you created in step 1.
3. Double-click the FSSO_Setup_edirectory file to start the installation wizard.
4. Select **Next**.

5. Read and accept the license agreement. Select **Next**.
6. Optionally, change the installation location. Select **Next**.
7. Enter:

eDirectory Server	
Server Address	Enter the IP address of the eDirectory server.
Use secure connection (SSL)	Select to connect to the eDirectory server using SSL security.
Search Base DN	Enter the base Distinguished Name for the user search.

eDirectory Authentication	
Username	Enter a username that has access to the eDirectory, using LDAP format.
User password	Enter the password.

8. Select **Next**.
9. Select **Install**. When the installation completes, select **Finish**.

Updating FSSO agents on Windows AD

After FSSO is installed on your network, you may want to upgrade to a newer version. The following procedure helps ensure you have a trouble free upgrade. How you update FSSO depends on if you are using polling mode or DCAgent mode.

For polling mode, since there are no DC agents you only need to upgrade the Collector. However in DCAgent mode, each DC Agent must be updated as well.

To update FSSO in DC Agent mode:

1. Go to the system32 directory on all DC's and rename the `dcagent.dll` file to `dcagent.dll.old`. This ensures the when the upgrade is pushed to the DC it does not overwrite the old file. If there are any problems this makes it easy to revert to the old version.
2. Run the FSSO setup .exe file to update the collector. When this is completed, ignore any reboot message.
3. Go to **Programs > Fortinet > Fortinet Single Sign On Agent > Install DC Agent** and push the DC agent out to all servers. All DC's will now need to be rebooted so that the new DLL file is loaded.
4. After the reboot, go to all DC's and delete the `dcagent.dll.old` files.

Configuring the FSSO Collector agent for Windows AD

On the FortiGate unit, security policies control access to network resources based on user groups. With Fortinet Single Sign On, this is also true but each FortiGate user group is associated with one or more Windows AD user groups. This is how Windows AD user groups get authenticated in the FortiGate security policy.

Fortinet Single Sign On sends information about Windows user logons to FortiGate units. If there are many users on your Windows AD domains, the large amount of information might affect the performance of the FortiGate units.

To avoid this problem, you can configure the Fortinet Single Sign On Collector agent to send logon information only for groups named in the FortiGate unit's security policies. See Configuring FortiGate group filters on page 667.

On each server with a Collector agent, you will be

- Configuring Windows AD server user groups
- Configuring Collector agent settings, including the domain controllers to be monitored
- Selecting Domain Controllers and working mode for monitoring
- Configuring Directory Access settings
- Configuring the Ignore User List
- Configuring FortiGate group filters for each FortiGate unit
- Configuring FSSO ports
- Configuring alternate user IP address tracking
- Viewing FSSO component status

Configuring Windows AD server user groups

FortiGate units control network resource access at the group level. All members of a user group have the same network access as defined in FortiGate security policies.

You can use existing Windows AD user groups for authentication to FortiGate units if you intend that all members within each group have the same network access privileges.

Otherwise, you need to create new user groups for this purpose.

If you change a user's group membership, the change does not take effect until the user logs off and then logs on again.

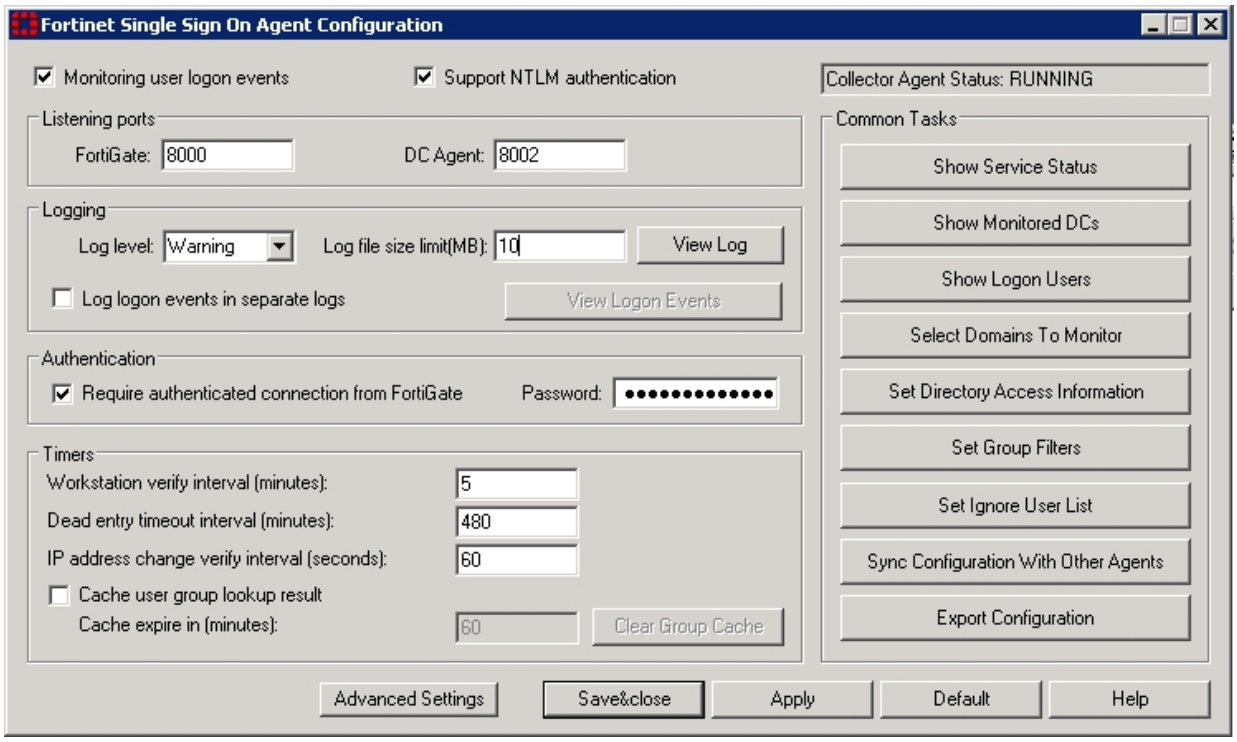
The FSSO Agent sends only Domain Local Security Group and Global Security Group information to FortiGate units. You cannot use Distribution group types for FortiGate access. No information is sent for empty groups.

Refer to Microsoft documentation for information about creating and managing Windows AD user groups.

Configuring Collector agent settings

You need to configure which domain controllers the Collector agent will use and which domains to monitor for user logons. You can also alter default settings and settings you made during installation. These tasks are accomplished by configuring the FSSO Collector Agent, and selecting either Apply to enable the changes.

At any time to refresh the FSSO Agent settings, select Apply.



To configure the Collector agent:

1. From the Start menu, select **Programs > Fortinet > Fortinet Single Sign-On Agent > Configure Fortinet Single Sign-On Agent**.
2. Enter the following information.

Monitoring user logon events	By default, this is enabled to automatically authenticate users as they log on to the Windows domain. Disable the Monitor feature only if you have a large network where this feature will slow responses too much.
Support NTLM authentication	By default, this is enabled to facilitate logon of users who are connected to a domain that does not have the FSSO DC Agent installed. Disable NTLM authentication only if your network does not support NTLM authentication for security or other reasons.
Collector Agent Status	Shows RUNNING when Collector agent is active.
Listening ports	You can change FSSO Collector Agent related port numbers if necessary.
FortiGate	TCP port for FortiGate units. Default 8000.
DC Agent	UDP port for DC Agents. Default 8002.
Logging	
Log level	Select the minimum severity level of logged messages.

	Log file size limit (MB)	Enter the maximum size for the log file in MB. Default is 10.
	View Log	View all Fortinet Single Sign On agent logs.
	Log logon events in separate logs	Record user login-related information separately from other logs. The information in this log includes: • data received from DC agents • user logon/logoff information • workstation IP change information • data sent to FortiGate units
	View Logon Events	If **Log logon events in separate logs** is enabled, you can view user login-related information.
Authentication		
	Require authenticated connection from FortiGate	Select to require the FortiGate unit to authenticate before connecting to the Collector agent.
	Password	Enter the password that FortiGate units must use to authenticate. The maximum password length is 15 characters. The default password is “fortinetcanada”. It is highly recommended to modify this password.
Timers		
	Workstation verify interval (minutes)	Enter the interval in minutes at which the Fortinet Single Sign On Collector agent connects to client computers to determine whether the user is still logged on. The default is every 5 minutes. The interval may be increased if your network has too much traffic. **Note:** This verification process creates security log entries on the client computer. If ports 139 or 445 cannot be opened on your network, set the interval to 0 to prevent checking. See Configuring FSSO ports on page 669.
	Dead entry timeout interval	Enter the interval in minutes after which Fortinet Single Sign On Agent purges information for user logons that it cannot verify. The default is 480 minutes (8 hours). Dead entries usually occur because the computer is unreachable (such as in standby mode or disconnected) but the user has not logged off. A common reason for this is when users forget to logoff before leaving the office for the day. You can also prevent dead entry checking by setting the interval to 0.

IP address change verify interval	Fortinet Single Sign On Agent periodically checks the IP addresses of logged-in users and updates the FortiGate unit when user IP addresses change. IP address verification prevents users from being locked out if they change IP addresses, as may happen with DHCP assigned addresses. Enter the verification interval in seconds. The default is 60 seconds. You can enter 0 to prevent IP address checking if you use static IP addresses. This does not apply to users authenticated through NTLM.
Cache user group lookup result	Enable caching. Caching can reduce group lookups and increase performance.
Cache expire in (minutes)	Fortinet Single Sign On Agent caches group information for logged-in users. Enter the duration in minutes after which the cache entry expires. If you enter 0, the cache never expires. A long cache expire interval may result in more stale user group information. This can be an issue when a user's group information is changed.
Clear Group Cache	Clear group information of logged-in users. This affects all logged-in users, and may force them to re-logon.

3. You can select **Save&Close** now or leave the agent configuration window open to complete additional configuration in the following sections.

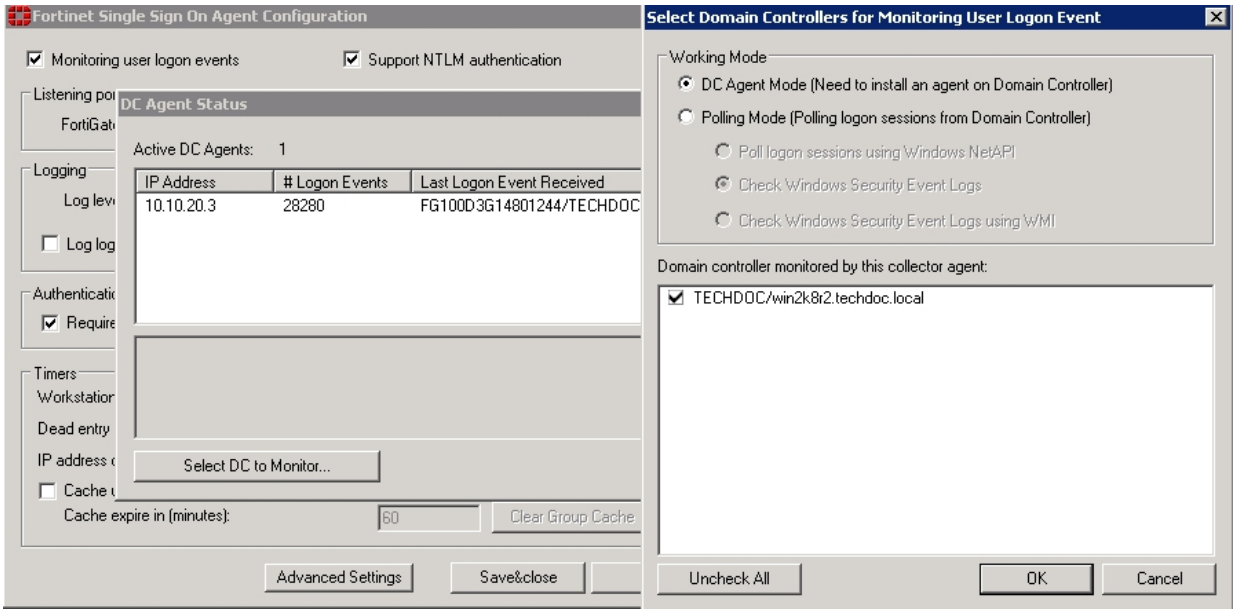
To view the version and build number information for your FSSO Collector Agent configuration, selecting the Fortinet icon in the upper left corner of the Collector agent Configuration screen and select **About Fortinet Single Sign On Agent configuration.**

Selecting Domain Controllers and working mode for monitoring

You can change which DC agents are monitored or change the working mode for logon event monitoring between DC agent mode and polling mode.

When polling mode is selected, it will poll port 445 of the domain controller every few seconds to see who is logged on.

1. From the Start menu select **Programs > Fortinet Fortinet Single Sign-On Agent > Configure Fortinet Single Sign On Agent**.
2. In the **Common Tasks** section, select **Show Monitored DCs**.
3. Select **Select DC to Monitor**.



4. Choose the **Working Mode:**
   - **DC Agent mode** — a Domain Controller agent monitors user logon events and passes the information to the Collector agent. This provides reliable user logon information, however you must install a DC agent on every domain controller in the domain.
   - **Polling mode** — the Collector agent polls each domain controller for user logon information. Under heavy system load this might provide information less reliably. However installing a DC agent on each domain controller is not required in this mode.
5. You also need to choose the method used to retrieve logon information:
   - Poll logon sessions using Windows NetAPI
   - Check Windows Security Event Logs
   - Check Windows Security Event Logs using WMI

   For more information about these options, see Polling mode on page 649.
6. Select **OK**.
7. Select **Close**.
8. Select **Save & Close**.

Configuring Directory Access settings

The FSSO Collector Agent can access Windows Active Directory in one of two modes:

- Standard — the FSSO Collector Agent receives group information from the Collector agent in the **domain\user** format. This option is available on FortiOS 3.0 and later.
- Advanced — the FSSO Collector Agent obtains user group information using LDAP. The benefit of this method is that it is possible to nest groups within groups. This is option is available on FortiOS 3.0 MR6 and later. The group information is in standard LDAP format.

If you change AD access mode, you must reconfigure your group filters to ensure that the group information is in the correct format.

To configure Directory Access settings:

1. From the Start menu select **Programs > Fortinet > Fortinet Single Sign On Agent > Configure Fortinet Single Sign On Agent**.
2. In the **Common Tasks** section, select **Set Directory Access Information**.
   The **Set Directory Access Information** dialog box opens.
3. From the **AD access mode** list, select either **Standard** or **Advanced**.
4. If you selected Advanced AD access mode, select **Advanced Setting** and configure the following settings and then select **OK**:

AD server address	Enter the address of your network's global catalog server.
AD server port	The default AD server port is 3268. This must match your server port.
BaseDN	Enter the Base distinguished name for the global catalog. This is the point in the tree that will be considered the starting point by default-See following example.
Username	If the global catalog accepts your Fortinet Single Sign On Agent agent's credentials, you can leave these fields blank. Otherwise, enter credentials for an account that can access the global catalog.
Password	

BaseDN example

An example DN for Training Fortinet Canada is `ou=training, ou=canada, dc=fortinet, dc=com`. If you set the **BaseDN** to `ou=canada, dc=fortinet, dc=com` then when Fortinet Single Sign On Agent is looking up user credentials, it will only search the Canada organizational unit, instead of all the possible countries in the company. Its a short cut to entering less information and faster searches.

However, you may have problems if you narrow the BaseDN too much when you have international employees from the company visiting different offices. If someone from Fortinet Japan is visiting the Canada office in the example above, their account credentials will not be matched because they are in `ou=japan, dc=fortinet, dc=com` instead of the BaseDN `ou=canada, dc=fortinet, dc=com`. The easy solution is to change the BaseDN to simply be `dc=fortinet, dc=com`. Then any search will check all the users in the company.

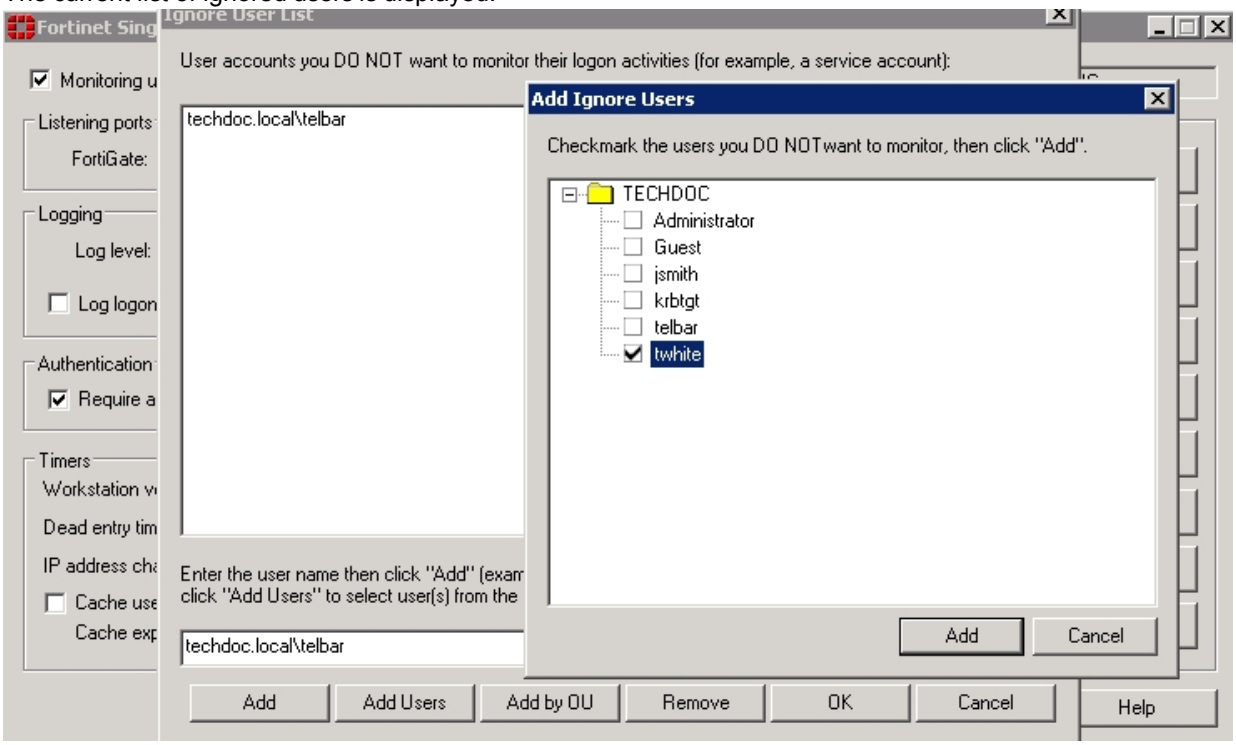
Configuring the Ignore User List

The Ignore User List excludes users that do not authenticate to any FortiGate unit, such as system accounts. The logons of these users are not reported to FortiGate units. This reduces the amount of required resources on the FortiGate unit especially when logging logon events to memory.

To configure the Ignore User List:

1. From the Start menu select **Programs > Fortinet > Fortinet Single Sign On Agent > Configure Fortinet Single Sign On Agent**.

2. In the **Common Tasks** section, select **Set Ignore User List**.
   The current list of ignored users is displayed:



3. Do any of the following:
   - To remove a user from the list, select the the username and then select **Remove**. The user's login is no longer ignored.
   - To add users to be ignored,
     - enter the username in the format **domain\username** and select **Add** or
     - select **Add Users**, an **Add Ignore Users** window is displayed, checkmark the users you do not want to monitor, then select **Add** or
     - select **Add by OU**, an **Add Ignore Users by OU** window is displayed, select an OU from the directory tree, then select **Add**. All users under the selected OU will be added to the ignore user list.
4. Select **OK**.

Configuring FortiGate group filters

FortiGate group filters actively control which user logon information is sent to each FortiGate unit. You need to configure the group filter list so that each FortiGate unit receives the correct user logon information for the user groups that are named in its security policies. These group filters help limit the traffic sent to the FortiGate unit, and help limit the logon events logged.

The maximum number of Windows AD user groups allowed on a FortiGate depends on the model. Low end models support 256 Windows AD user groups, where mid and high end models support 1024 groups. This is per VDOM if VDOMs are enabled on the FortiGate unit.

You do not need to configure a group filter on the Collector agent if the FortiGate unit retrieves group information from Windows AD using LDAP. In that case, the Collector agent uses the list of groups you selected on the FortiGate unit as its group filter.

The filter list is initially empty. You need to configure filters for your FortiGate units using the Add function. At a minimum, create a default filter that applies to all FortiGate units without a defined filter.

If no filter is defined for a FortiGate unit and there is no default filter, the Collector agent sends all Windows AD group and user logon events to the FortiGate unit. While this normally is not a problem, limiting the amount of data sent to the FortiGate unit improves performance by reducing the amount of memory the unit uses to store the group list and resulting logs.

To configure a FortiGate group filter:

1. From the Start menu select **Programs > Fortinet > Fortinet Single Sign On Agent > Configure Fortinet Single Sign On Agent**.
2. In the **Common Tasks** section, select **Set Group Filters**.
   The FortiGate Filter List opens. It has the following columns:

FortiGate SN	The serial number of the FortiGate unit to which this filter applies.
Description	An optional description of the role of this FortiGate unit.
Monitored Groups	The Windows AD user groups that are relevant to the security policies on this FortiGate unit.
Add	Create a new filter.
Edit	Modify the filter selected in the list.
Remove	Remove the filter selected in the list.
OK	Save the filter list and exit.
Cancel	Cancel changes and exit.

3. Select **Add** to create a new filter. If you want to modify an existing filter, select it in the list and then select **Edit**.
4. Enter the following information and then select **OK**.

Default filter	Select to create the default filter. The default filter applies to any FortiGate unit that does not have a specific filter defined in the list.
FortiGate Serial Number	Enter the serial number of the FortiGate unit to which this filter applies. This field is not available if Default is selected.
Description	Enter a description of this FortiGate unit's role in your network. For example, you could list the resources accessed through this unit. This field is not available if Default is selected.
Monitor the following groups	The Collector agent sends to the FortiGate unit the user logon information for the Windows AD user groups in this list. Edit this list using the Add, Advanced and Remove buttons.

Add	In the preceding single-line field, enter the Windows AD domain name and user group name, and then select Add. If you don't know the exact name, use the Advanced button instead. The format of the entry depends on the AD access mode (see Configuring Directory Access settings on page 665): Standard: Domain\Group Advanced: cn=group, ou=corp, dc=domain
Advanced	Select **Advanced**, select the user groups from the list, and then select **Add**.
Remove	Remove the user groups selected in the monitor list.

Configuring FSSO ports

For FSSO to function properly a small number of TCP and UDP ports must be open through all firewalls on the network. There ports listed in this section assume the default FSSO ports are used.

TCP ports for FSSO agent with client computers

Windows AD records when users log on but not when they log off. For best performance, Fortinet Single Sign On Agent monitors when users log off. To do this, Fortinet Single Sign On Agent needs read-only access to each client computer's registry over TCP port 139 or 445. Open at least one of these ports — ensure it is not blocked by firewalls.

If it is not feasible or acceptable to open TCP port 139 or 445, you can turn off Fortinet Single Sign On Agent logoff detection. To do this, set the Collector agent **workstation verify interval** to 0. The FSSO Collector Agent assumes that the logged on computer remains logged on for the duration of the Collector agent dead entry timeout interval — by default this is eight hours.

Configuring ports on the Collector agent computer

On the computer where you install the Collector agent, you must make sure that the firewall does not block the listening ports for the FortiGate unit and the DC Agent. By default, these are TCP port 8000 and UDP port 8002. For more information about setting these ports, see Configuring FSSO Advanced Settings on page 675.

Configuring alternate user IP address tracking

In environments where user IP addresses change frequently, you can configure Fortinet Single Sign On Agent to use an alternate method to track user IP address changes. Using this method, Fortinet Single Sign On Agent responds more quickly to user IP address changes because it directly queries workstation IP addresses to match users and IP addresses.

This feature requires FSAE version 3.5.27 or later, Fortinet Single Sign On Agent any version, and FortiOS 3.0 MR7 or later.

To configure alternate user IP address tracking:

1. On the computer where the Collector agent is installed, go to **Start > Run**.
2. Enter `regedit` or `regedt32` and select **OK**.
   The Registry Editor opens.
3. Find the registry key HKEY_LOCAL_MACHINE\SOFTWARE\Fortinet\FSAE\collectoragent.
4. Set the supportFSAEauth value (dword) to 00000001.
   If needed, create this new dword.
5. Close the Registry Editor.
6. From the Start menu select **Programs > Fortinet > Fortinet Single Sign On Agent > Configure Fortinet Single Sign On Agent**.
7. Select **Apply**.
   The Fortinet Single Sign On Agent service restarts with the updated registry settings.

Viewing FSSO component status

It is important to know the status of both your Collector agents and DC agents.

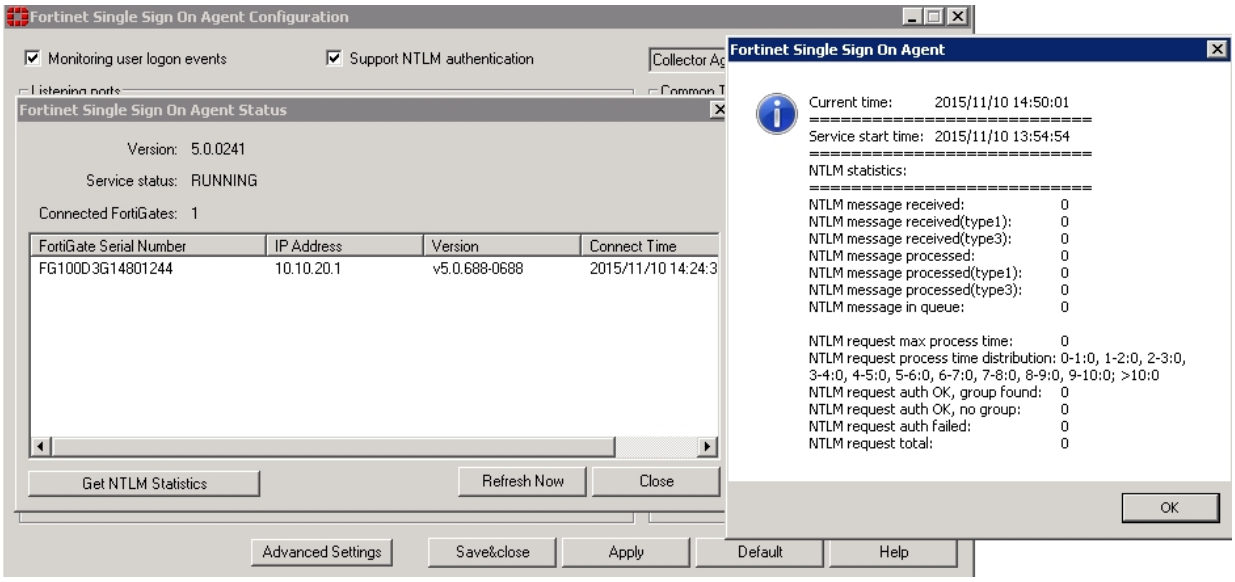
Viewing Collector agent status

Use the **Show Service Status** to view your Collector agent information in the Status window. The Status window displays:

- the version of the software
- the status of the service
- the number of connected FortiGate units
- connected FortiGate information such as serial number, IP address, and connect time

To view Collector agent status:

1. From the Start menu select **Programs > Fortinet > Fortinet Single Sign On Agent > Configure Fortinet Single Sign On Agent**.
2. In the **Common Tasks** section, select **Show Service Status**.
   The Fortinet Single Sign On Collector agent Status window opens.
3. Optionally select **Get NTLM statistics** in the Status window to display NTLM information such as number of messages received, processed, failed, in the queue.



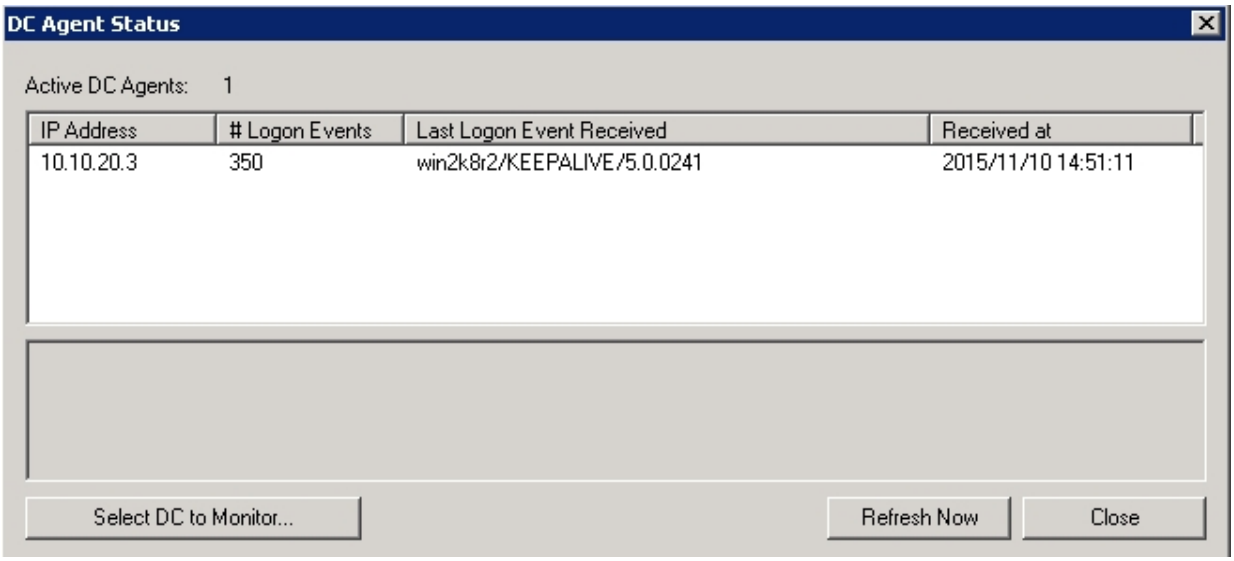
Viewing DC agent status

Use the **Show Monitored DCs** to view the status of DC agents.

To view domain controller agent status:

1. From the Start menu select **Programs > Fortinet > Fortinet Single Sign On Agent > Configure Fortinet Single Sign On Agent**.
2. In the **Common Tasks** section, select **Show Monitored DCs**.
   For each DC Agent, the following information is displayed:
   - IP address
   - number of logon events received
   - the last logon event
   - when last logon was received

To change which DC agents are monitored or change the working mode for logon event monitoring, select **Select DC to Monitor**



Configuring the FSSO TS agent for Citrix

The FSSO TS agent works with the same FSSO Collector agent that is used for integration with Windows Active Directory. Install the Collector agent first. Follow the Collector agent installation procedure in Collector agent installation on page 656.

FortiOS 5.6 supports FSSO DC/TS Agent v.5.x.

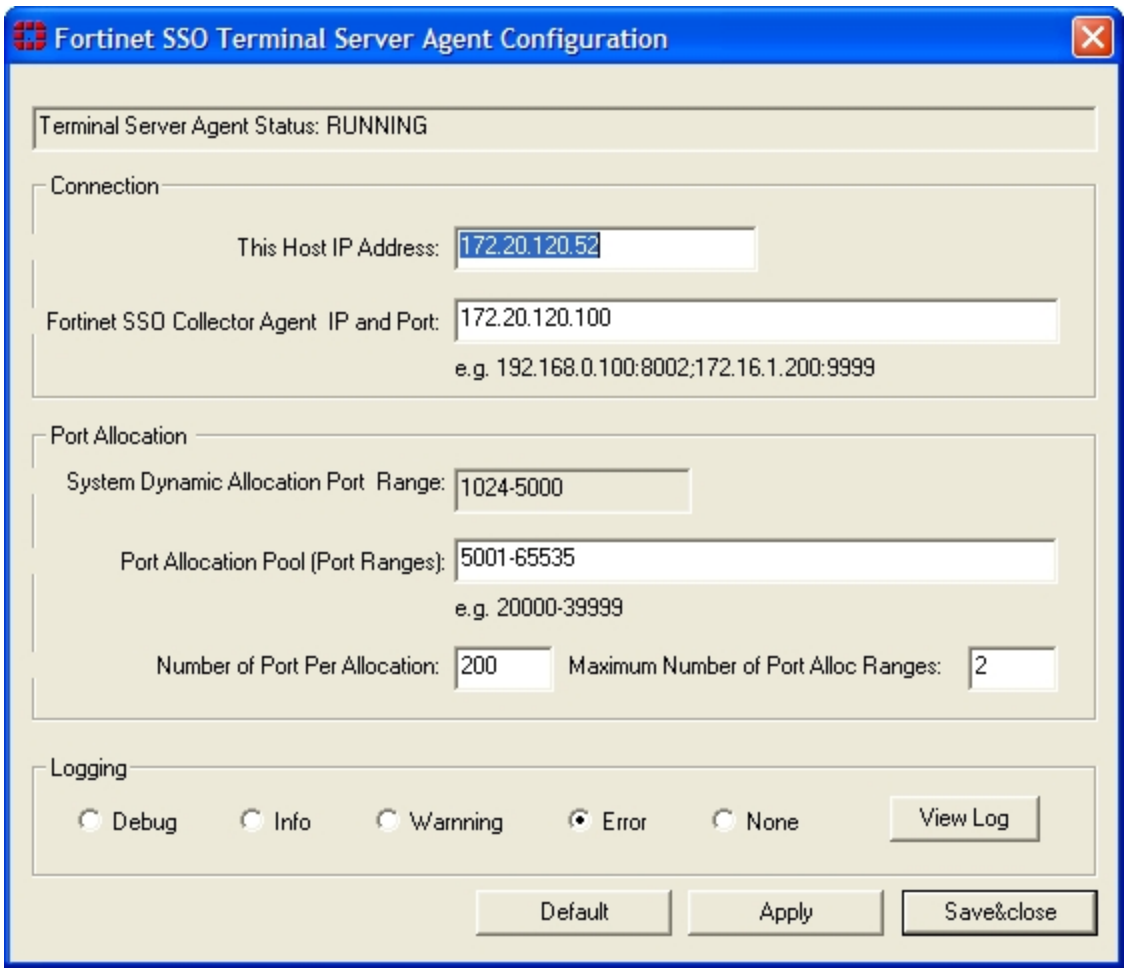
Configuration steps include:

- Install the Fortinet Citrix FSSO agent on the Citrix server.
- Install the Fortinet FSSO collector on a server on the network.
- Add the Citrix FSSO agent to the FortiGate Single-sign-On configuration.
- Add Citrix FSSO groups and users to an FSSO user group.
- Add an FSSO identity-based security policy that includes the Citrix FSSO user groups.

To change the TS agent configuration, select from the Start menu **Programs > Fortinet > Fortinet Single Sign-On Agent > TSAgent Config**. In addition to the host and Collector agent IP addresses that you set during installation, you can adjust port allocations for Citrix users. When a Citrix user logs on, the TS agent assigns that user a range of ports. By default each user has a range of 200 ports.

Fortinet SSO Collector Agent IP and Port needs to point to the current configured listening port on the collector which is port 8002 by default. Though it may be configured to a custom port.

Configuring the TS agent



Configuring FSSO with Novell networks

You need to configure the eDirectory agent for it to communicate with eDirectory servers. You may have provided some of this information during installation.

This section includes:

- Configuring the eDirectory agent
- Adding an eDirectory server
- Configuring a group filter

Configuring the eDirectory agent

You need to configure the eDirectory agent for it to communicate with eDirectory servers.

To configure the eDirectory agent:

1. From the Start menu select **Programs > Fortinet > eDirectory Agent > eDirectory Config Utility**.
2. The eDirectory Agent Configuration Utility dialog opens. Enter the following information and select **OK**.

eDirectory Authentication	
Username	Enter a username that has access to the eDirectory, using LDAP format.
Password	Enter the password.
Listening port	Enter the TCP port on which Fortinet Single Sign On Agent listens for connections from FortiGate units. The default is 8000. You can change the port if necessary.
Refresh interval	Enter the interval in seconds between polls of the eDirectory server to check for new logons. The default is 30 seconds.

FortiGate Connection Authentication	
Require authenticated connection from FortiGate	Select to require the FortiGate unit to authenticate before connecting to the eDirectory Agent.
Password	Enter the password that FortiGate units must use to authenticate. The maximum password length is 15 characters. The default password is “FortinetCanada”.
User logon Info Search Method	Select how the eDirectory agent accesses user logon information: **LDAP** or **Native** (Novell API). LDAP is the default. If you select **Native**, you must also have the Novell Client installed on the PC.

Logging	
Log file size limit (MB)	Enter the maximum size for the log file in MB.
View Log	View the current log file.
Dump Session	List the currently logged-on users in the log file. This can be useful for troubleshooting.
Log level	Select **Debug, Info**, **Warning** or **Error** as the minimum severity level of message to log or select **None** to disable logging.

eDirectory Server List	
Add	Add an eDirectory server. See Adding an eDirectory server on page 675.
Delete	Delete the selected eDirectory server.
Edit	Modify the settings for the selected server.
Set Group Filters...	Select the user groups whose user logons will be reported to the FortiGate unit. This is used only if user groups are not selected on the FortiGate unit.

Adding an eDirectory server

Once the eDirectory agent is configured, you add one or more eDirectory servers.

To add an eDirectory server:

1. In the eDirectory Agent Configuration Utility dialog box (see the preceding procedure, Configuring the eDirectory agent), select **Add**.
2. The eDirectory Setup dialog box opens. Enter the following information and select OK:

eDirectory Server Address	Enter the IP address of the eDirectory server.
Port	If the eDirectory server does not use the default port 389, clear the **Default** check box and enter the port number.
Use default credential	Select to use the credentials specified in the eDirectory Configuration Utility. See Configuring the eDirectory agent on page 673. Otherwise, leave the check box clear and enter a username and Password below.
User name	Enter a username that has access to the eDirectory, using LDAP format.
User password	Enter the password.
Use secure connection (SSL)	Select to connect to the eDirectory server using SSL security.
Search Base DN	Enter the base Distinguished Name for the user search.

Configuring a group filter

The eDirectory agent sends user logon information to the FortiGate unit for all user groups unless you either configure an LDAP server entry for the eDirectory on the FortiGate unit and select the groups that you want to monitor or configure the group filter on the eDirectory agent.

If both the FortiGate LDAP configuration and the eDirectory agent group filter are present, the FortiGate user group selections are used.

To configure the group filter:

1. From the Start menu select **Programs > Fortinet > eDirectory Agent > eDirectory Config Utility**.
2. Select **Set Group Filters**.
3. Do one of the following:
   - Enter group names, then select **Add**.
   - Select **Advanced**, select groups, and then select **Add**.
4. Select **OK**.

Configuring FSSO Advanced Settings

Depending on your network topologies and requirement, you may need to configure advanced settings in the FSSO Colloctor agent.To do so, from the Start menu, select **Programs > Fortinet > Fortinet Single Sign-On Agent > Configure Fortinet Single Sign-On Agent**, then from the **Common Tasks** section, select **Advanced Settings**.

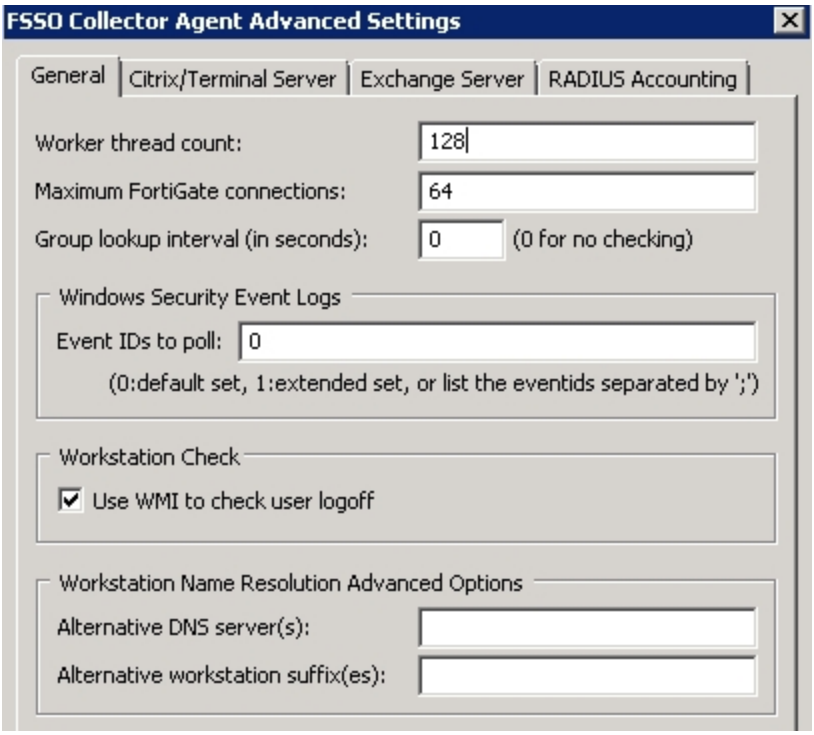
This section include :

- General Settings
- Citrix/Terminal Server
- Exchange Server
- RADIUS Accounting

General Settings

In the General tab, enter the following information and select **OK**.

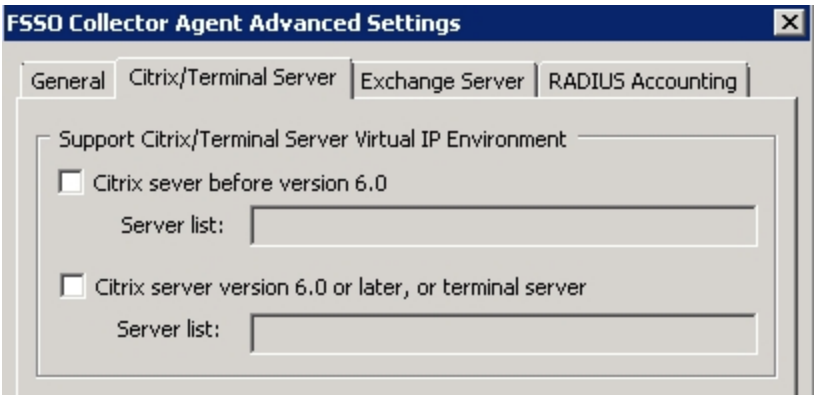
Worker thread count	Number of threads started in the CA process. Default is128 on CA version 5.0.0241.
Maximum FortiGate connections	Number of FortiGates can be connected to the CA. Default is 64.
Group look-up interval	The interval in seconds to lookup users/groups. If an AD group membership of currently logged on user, CA can detect this and update information on the FortiGate. Enter 0 for no checking.
Windows security Event logs	Choose the event logs to poll.
Event IDs to poll	0:Default set, it includes Kerberos authentication event logs : 672 for Windows server 2003, 4768 for Windows server 2008 and 2012 and NTLM authentication event logs : 680 for Windows server 2003, 4776 for Windows server 2008 and 2012. 1: Extended set, it includes Kerberos service ticket event logs : 673 for Windows server 2003, 4769 for Windows server 2008 and 2012. Service tickets are obtained whenever a user or computer accesses a server on the network. List the event ids separated by ";".
Workstation Check	Optionally enable **Use WMI to check user logoff** for the collector agent to query whether users is still logged on.
Workstation Name Resolution Advance Options	
Alternative DNS server(s)	Collector Agent uses the DNS server configured on the machine it is running on by default. If CA should use another DNS server then one or more alternative DNS server can be configured here.
Alternative workstation suffix(es)	If only host name is available CA uses the default domain suffix to build a FQDN for DNS queries. In case CA should use a different suffix, it can be configured as well.



Citrix/Terminal Server

In the Citrix/Terminal Server tab, enter the following information and select **OK**.

Support Citrix/Terminal Server Virtual IP Environment	When Citrix server are configured with VIP, CA can get user logon events from theses server. Citrix changed their interface and data format so version of Citrix server is important.
Citrix server before version 6.0	Enable this option if you Citrix server version is before 6.0.
Server list	Enter the list of servers separated by colon.
Citrix server version 6.0 or later, or Terminal Server	Enable this option if you Citrix server version is 6.0 or later.
Server list	Enter the list of servers separated by colon.

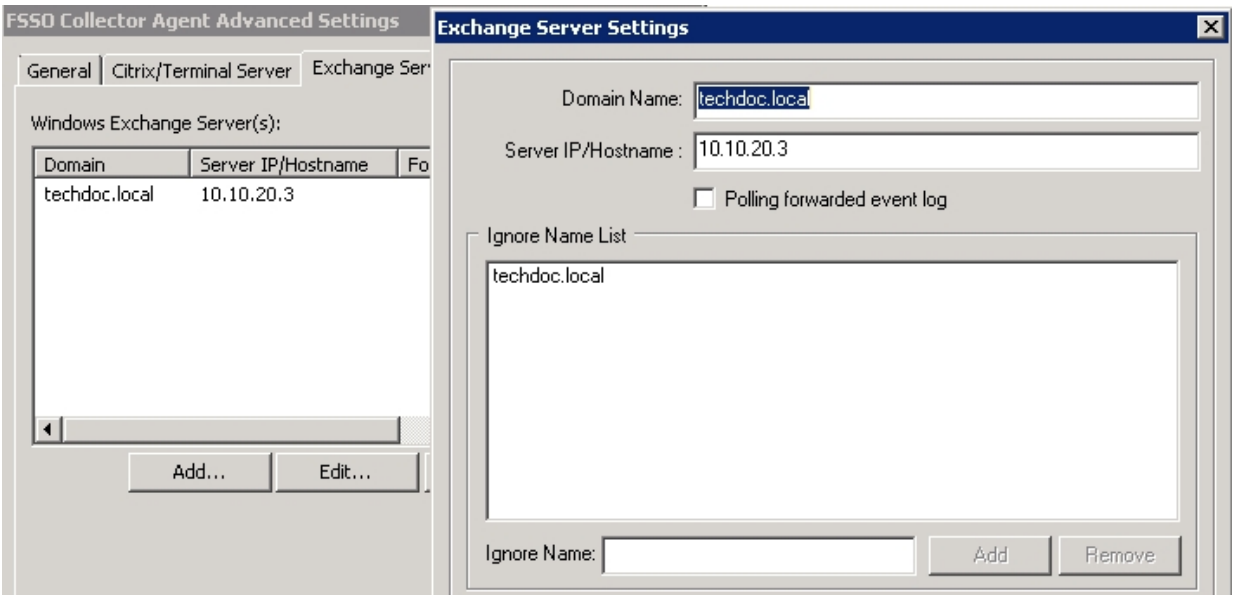


Exchange Server

FSSO supports monitoring Microsoft Exchange Server. This is useful for situation that the user use the domain account to access their email, but client device might or might not be in the domain. Support for Exchange server is configured on the Back-end FSSO collector agent under **Advanced Settings** > **Exchange Server**.

Select **Add** and enter the following information and select **OK**.

Domain Name	Enter your domain name.
Server IP/Hostname	Enter the IP address or the hostname of your exchange server.
Polling forwarded event log	This option for scenarios when you do not want that CA polls the Exchange Server logs directly. In this case you need to configure event log forwarding on the Exchange server. Exchange event logs can be forwarded to any member server. If you enable this, instead of the IP of the Exchange server configured in the previous step, you must then configure the IP of this member server. CA will then contact the member server.
Ignore Name	Because CA will also check Windows log files for logon events and when a user authenticates to Exchange Server there is also a logon event in Windows event log, which CA will read and this will overwrite the Exchange Server logon event (ES-EventLog) on CA. So it is recommended to set the ignore list to the domain the user belongs to. To do so, enter the domain name in the **Ignore Name** field and select **Add**.



RADIUS Accounting

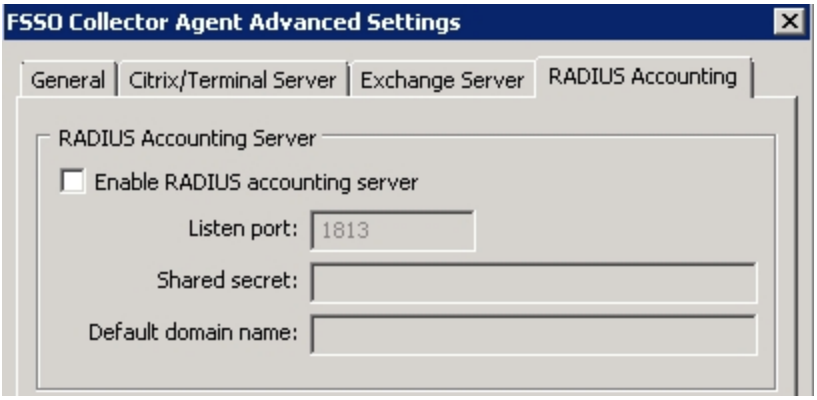
A RADIUS server must be configured in your network to send accounting messages to the Collector Agent which can be configured to work with most RADIUS-based accounting systems. In most cases, you only need to do the following to your RADIUS accounting system:

- Add a user group name field to customer accounts on the RADIUS server so that the name is added to the RADIUS Start record sent by the accounting system to the Collector Agent. User group names do not need to be added for all users, only to the accounts of users who will use RADIUS Accounting feature on the Collector Agent.
- Configure your accounting system to send RADIUS Start records to the Collector Agent.

The Collocter Agent should be configured to listen for RADIUS accounting messages as following.

RADIUS Accounting Server	
Enable RADIUS Accounting Server	Enable this option to allow the CA to gather information about authenticated users via a RADIUS server and send these information to the FortiGate unit for monitoring.
Listen port	The port on which CA listens for RADIUS accounting messages. Default RADIUS accounting is 1813, but if RADIUS server sends accounting messages on different port, value can be configured here.
Shared secret	Common secret between CA and RADIUS server.

Default domain name	This should be the AD domain for which this CA is configured. In this case user name in RADIUS accounting message can be in simple format like `user1`. If this value is empty, then user name in RADIUS accounting message must be in one of these formats `user1@domain`, `Domain\user1` or `domain/user1`. CA will use user name and domain to query group membership of user. Client IP address (Framed IP) should also be in RADIUS accounting message, so that CA can forward user name, IP address and groups to the FortiGate.



Configuring FSSO on FortiGate units

To configure your FortiGate unit to operate with agent-based FSSO, you

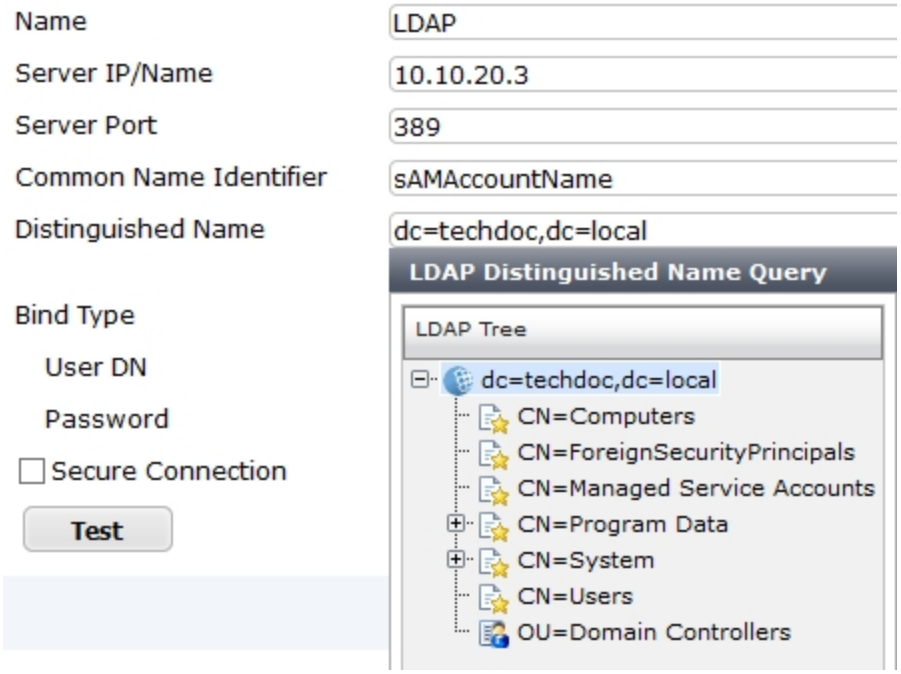
- Configure any access to LDAP servers that might be necessary. Skip this step if you are using FSSO Standard mode. See Configuring LDAP server access on page 680.
- Specify the Collector agent or Novell eDirectory agent that will provide user logon information. See Specifying your Collector agents or Novell eDirectory agents on page 682.
- Add Active Directory user groups to FortiGate user groups. See Creating Fortinet Single Sign-On (FSSO) user groups on page 683.
- Create security policies for FSSO-authenticated groups. See Creating security policies on page 684.
- Optionally, specify a guest security policy to allow guest access. See Enabling guest access through FSSO security policies on page 685.

Configuring LDAP server access

LDAP access is required if your network has a Novell eDirectory agent or a Collector agent using Windows Advanced AD access mode. If you are using FSSO Standard mode, go to Specifying your Collector agents or Novell eDirectory agents on page 682.

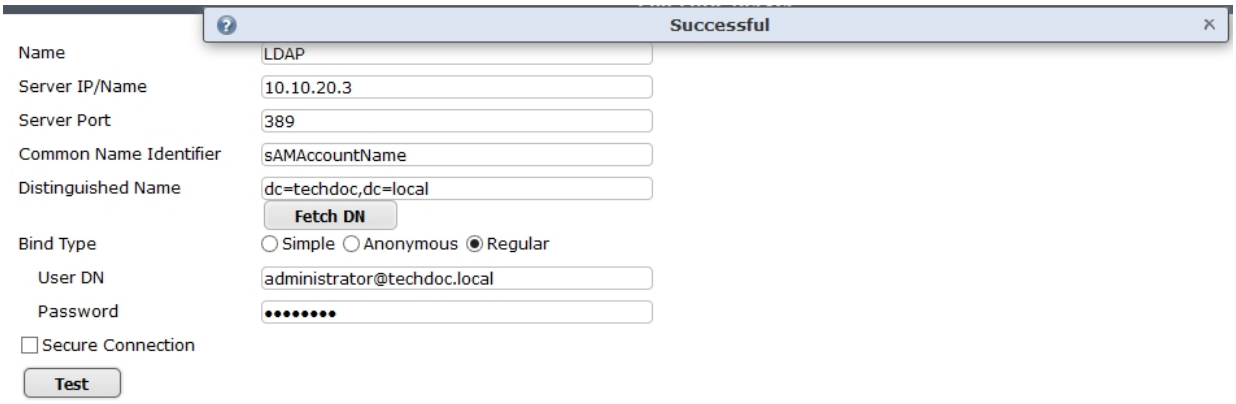
1. Go to **User & Device > LDAP Servers** and select **Create New**.
2. Enter the **Server IP/Name** and **Server Port** (default 389).
3. In the **Common Name Identifier** field, enter **sAMAccountName**.The default common name identifier is `cn`. This is correct for most LDAP servers. However some servers use other identifiers such as `uid`.

4. In the **Distinguished Name** field, enter your organization distinguished name. In this example, Distinguished Name is dc=techdoc,dc=local
5. Select **Fetch DN**, this will fetch the Windows AD directory.



6. Set **Bind Type** to **Regular.**
7. In the **User DN** field, enter the administrative account name that you created for FSSO.
   For example, if the account is administrator, enter “administrator@techdoc.local”.
8. Enter the administrative account password in the **Password** field.
9. Optionally select **Secure Connection**.
   - In the **Protocol** field, select **LDAPS** or **STARTTLS**.
   - In the **Certificate** field, select the appropriate certificate for authentication.

   Note that you need to configure the Windows AD for secure connection accordingly.
10. Select **OK**.
11. Test your configuration by selecting the **Test** button. A successful message confirming the right settings appears.



To configure LDAP for FSSO - CLI example:

```
config user ldap
   edit LDAP
      set server 10.10.20.3
      set cnid sAMAccountName
      set dn dc=techdoc,dc=local
      set type regular
      set username administrator@techdoc.local
      set password <your_password>
   next
end
```

Specifying your Collector agents or Novell eDirectory agents

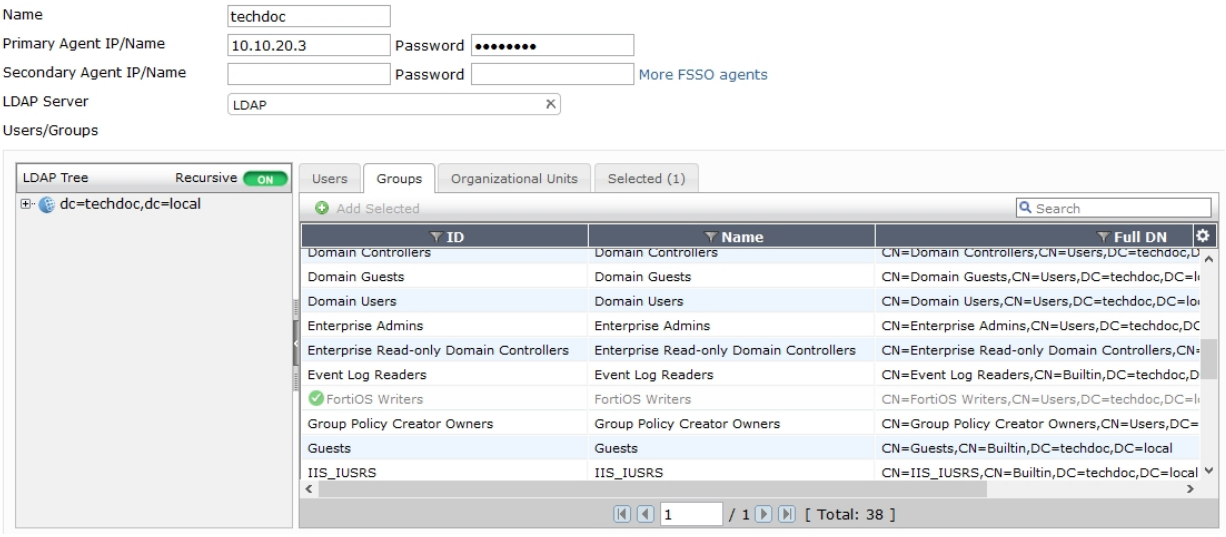
You need to configure the FortiGate unit to access at least one Collector agent or Novell eDirectory agent. You can specify up to five servers on which you have installed a Collector or eDirectory agent. The FortiGate unit accesses these servers in the order that they appear in the list. If a server becomes unavailable, the next one in the list is tried.

To specify Collector agents - web-based manager:

1. Go to **User & Device > Single Sign-On** and select **Create New**.
2. In **Type**, select **Fortinet Single-Sign-On Agent**.
3. Enter a **Name** for the Windows AD server. This name appears in the list of Windows AD servers when you create user groups.
4. Enter the following information for each of up to five collector agents and select **OK**:

Agent IP/Name	Enter the IP address or the name of the server where this agent is installed. Maximum name length is 63 characters. If the TCP port used for FSSO is not the default, 8000, you can change the setting in the CLI using the `config user fsso` command. See Configuring Collector agent settings on page 661.
Password	Enter the password for the Collector agent or eDirectory agent. For the Collector agent, this is required only if you configured the agent to require authenticated access.

5. For Novell eDirectory or Windows AD with Collector agent in Advanced AD access mode select the **LDAP Server** you configured previously. See Configuring LDAP server access on page 680.
6. In **Users/Groups**, select the **Users** or **Groups** or **Organizational Units** tab and then select the users or groups or OU that you want to monitor.
7. Select **OK**.



To specify the FSSO Collector agent - CLI:

In this example, the SSO server name is techdoc and the LDAP server is LDAP.

```
config user fsso
   edit techdoc
      set ldap-server LDAP
      set password <your_password>
      set server 10.10.20.3
      set port 8000
   end
```

Creating Fortinet Single Sign-On (FSSO) user groups

You cannot use Windows or Novell groups directly in FortiGate security policies. You must create FortiGate user groups of the FSSO type and add Windows or Novell groups to them.

To create a user group for FSSO authentication - web-based manager:

1. Go to **User & Device > User Groups**.
2. Select **Create New**.
   The New User Group dialog box opens.
3. In the **Name** box, enter a name for the group, FSSO_Internet_users for example.
4. In **Type**, select **Fortinet Single Sign-On (FSSO)**.
5. In **Members**, select the required **FSSO** groups.
6. Select **OK**.

To create the FSSO_Internet-users user group - CLI :

```
config user group
   edit FSSO_Internet_users
      set group-type fsso-service
      set member CN=Engineering,cn=users,dc=office,dc=example,dc=com
          CN=Sales,cn=users,dc=office,dc=example,dc=com
   end
```

Creating security policies

Policies that require FSSO authentication are very similar to other security policies. Using identity-based policies, you can configure access that depends on the FSSO user group. This allows each FSSO user group to have its own level of access to its own group of services

In this situation, Example.com is a company that has its employees and authentication servers on an internal network. The FortiGate unit intercepts all traffic leaving the internal network and requires FSSO authentication to access network resources on the Internet. The following procedure configures the security policy for FSSO authentication. FSSO is installed and configured including the RADIUS server, FSSO Collector agent, and user groups on the FortiGate

For the following procedure, the internal interface is `port1` and the external interface connected to the Internet is `port2`. There is an address group for the internal network called `company_network`. The FSSO user group is called `fsso_group`, and the FSSO RADIUS server is `fsso_rad_server`.

To configure an FSSO authentication security policy - web-based manager:

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter the following information.

Incoming Interface	port1
Source Address	company_network
Source User(s)	`fsso_group`
Outgoing Interface	port2
Destination Address	all
Schedule	always
Service	HTTP, HTTPS, FTP, and Telnet
Action	ACCEPT
NAT	ON
UTM Security Profiles	ON for AntiVirus, IPS, Web Filter, and Email Filter, all using default profiles.
Log Allowed Traffic	ON. Select **Security Events**.

3. Select **OK**.
4. Ensure the FSSO authentication policy is higher in the policy list than more general policies for the same interfaces.

To create a security policy for FSSO authentication - CLI:

```
config firewall policy
   edit 0
      set srcintf port1
      set dstintf port2
      set srcaddr company_network
```

```
    set dstaddr all
    set action accept
    set groups fsso_group
    set schedule always
    set service HTTP HTTPS FTP TELNET
    set nat enable
end
```

Here is an example of how this FSSO authentication policy is used. Example.com employee on the internal company network logs on to the internal network using their RADIUS username and password. When that user attempts to access the Internet, which requires FSSO authentication, the FortiGate authentication security policy intercepts the session, checks with the FSSO Collector agent to verify the user's identity and credentials, and then if everything is verified the user is allowed access to the Internet.

Users belonging to multiple groups

Before FSSO 4.0 MR3, if a user belonged to multiple user groups, the first security policy to match any group that user belonged too was the only security policy applied. If that specific group did not have access to this protocol or resource where another group did, the user was still denied access. For example, `test_user` belongs to `group1` and `group2`. There are two FSSO authentication policies — one matches `group1` to authenticate FTP traffic and one matches `group2` to authenticate email traffic. The `group1` policy is at the top of the list of policies. If `test_user` wants to access an email server, the first policy encountered for a group `test_user` belongs to is the `group1` policy which does not allow email access and `test_user` is denied access. This is despite the next policy allowing access to email. If the order was reversed in this case, the traffic would be matched and the user's traffic would be allowed through the firewall. However if the policy order was reversed, FTP traffic would not be matched.

As of FSSO 4.0 MR3, if a user belongs to multiple groups multiple then attempts to match the group are attempted if applicable. Using the above example, when the attempt to match the `group1` policy is made and fails, the next policy with a group that `test_user` is a member of is attempted. In this case, the next policy is matched and access is granted to the email server.

When configuring this example the only difference between the policies is the services that are listed and the FSSO user group name.

Authenticating through multiple groups allows administrators to assign groups for specific services, and users who are members of each group have access to those services. For example there could be an FTP group, an email group, and a Telnet group.

Enabling guest access through FSSO security policies

You can enable guest users to access FSSO security policies. Guests are users who are unknown to the Windows AD or Novell network and servers that do not logon to a Windows AD domain.

To enable guest access in your FSSO security policy, add an identity-based policy assigned to the built-in user group `SSO_Guest_Users`. Specify the services, schedule and protection profile that apply to guest users — typically guests receive reduced access to a reduced set of services.

IPv6 support for FSSO

FortiGate FSSO supports connecting to an FSSO agent over IPv6 and collecting and sending IPv6 details about endpoints. This is enforced in the same manner as IPv4 FSSO traffic.

Syntax

```
config user fsso
   edit <fsso agent name>
   set source-ip6 <IPv6 address for source>
end
```

FortiOS FSSO log messages

There are two types of FortiOS log messages — firewall and event. FSSO-related log messages are generated from authentication events. These include user logon and log off events, and NTLM authentication events. These log messages are central to network accounting policies, and can also be useful in troubleshooting issues. For more information on firewall logging, see "Enabling security logging". For more information on logging, see the FortiOS Handbook Log and Reporting guide.

Enabling authentication event logging

For the FortiGate unit to log events, that specific type of event must be enabled under logging.

When VDOMs are enabled certain options may not be available, such as CPU and memory usage events. You can enable event logs only when you are logged on to a VDOM; you cannot enable event logs globally.

To ensure you log all the events need, set the minimum log level to Notification or Information. Firewall logging requires Notification as a minimum. The closer to Debug level, the more information will be logged. While this extra information is useful, you must

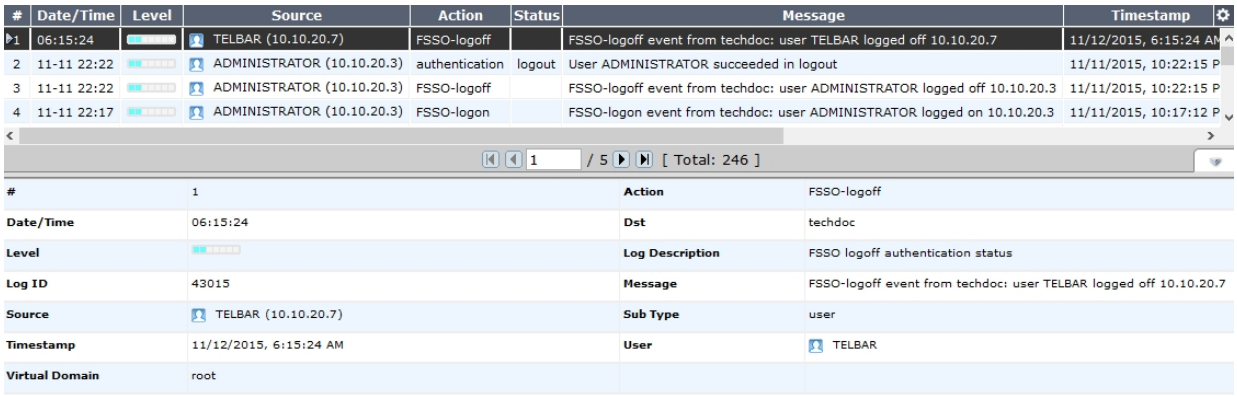
To enable event logging:

1. Go to **Log & Report > Log Settings**.
2. In **Event Logging**, select:

System activity event	All system-related events, such as ping server failure and gateway status.
User activity event	All administration events, such as user logins, resets, and configuration updates.

3. Optionally you can enable any or all of the other logging event options.
4. Select **Apply**.

Authentication log messages



#	Date/Time	Level	Source	Action	Status	Message	Timestamp
1	06:15:24		TELBAR (10.10.20.7)	FSSO-logoff		FSSO-logoff event from techdoc: user TELBAR logged off 10.10.20.7	11/12/2015, 6:15:24 AM
2	11-11 22:22		ADMINISTRATOR (10.10.20.3)	authentication	logout	User ADMINISTRATOR succeeded in logout	11/11/2015, 10:22:15 P
3	11-11 22:22		ADMINISTRATOR (10.10.20.3)	FSSO-logoff		FSSO-logoff event from techdoc: user ADMINISTRATOR logged off 10.10.20.3	11/11/2015, 10:22:15 P
4	11-11 22:17		ADMINISTRATOR (10.10.20.3)	FSSO-logon		FSSO-logon event from techdoc: user ADMINISTRATOR logged on 10.10.20.3	11/11/2015, 10:17:12 P

1 / 5 [Total: 246]

#	1	Action	FSSO-logoff
Date/Time	06:15:24	Dst	techdoc
Level		Log Description	FSSO logoff authentication status
Log ID	43015	Message	FSSO-logoff event from techdoc: user TELBAR logged off 10.10.20.7
Source	TELBAR (10.10.20.7)	Sub Type	user
Timestamp	11/12/2015, 6:15:24 AM	User	TELBAR
Virtual Domain	root		

List of FSSO related log messages

Message ID	Severity	Description
43008	Notification	Authentication was successful
43009	Notification	Authentication session failed
43010	Warning	Authentication locked out
43011	Notification	Authentication timed out
43012	Notification	FSSO authentication was successful
43013	Notification	FSSO authentication failed
43014	Notification	FSSO user logged on
43015	Notification	FSSO user logged off
43016	Notification	NTLM authentication was successful
43017	Notification	NTLM authentication failed

For more information on logging, see the FortiOS Handbook Log and Reporting guide.

Using filters

Logon events are detected by the FSSO CA by monitoring the Security Event logs. Additional logon event filters, such as ServiceName and ServiceID, have been implemented so as to avoid instances of conflicting security events, where existing FSSO logon user information could be overwritten and impact user connectivity.

The problem arises when a scenario such as the following occurs:

1. **User1** logs on to **PC1** on 1.1.1.1, which is logged as a successful Kerberos logon event with an ID of 4769.
2. The FortiGate creates an authenticated FSSO user log entry for **User1/1.1.1.1**.
3. **User1** then maps a network drive and uses credentials for **User2** to logon to the same PC (**PC1**).
4. The FortiGate sees this as a separate logon to **PC1** by a new user, **User2**. As a result, the log entry is updated to **User2/1.1.1.1**.
5. If **User2** is a member of a different user group to **User1** (i.e. has different access permissions), **User1** could lose access to their network resources.

The new filter makes the CA ignore the event log created when **User1** mapped a network drive, meaning that the original entry for **User1** will not be changed.

While this is a useful feature, it is highly recommended to test filters in a redundant test environment.

Testing FSSO

Once FSSO is configured, you can easily test to ensure your configuration is working as expected. For additional FSSO testing, see Troubleshooting FSSO on page 688.

1. Logon to one of the stations on the FSSO domain, and access an Internet resource.
2. Connect to the CLI of the FortiGate unit, and if possible log the output.
3. Enter the following command:
   ```
   diagnose debug authd fsso list
   ```
4. Check the output. If FSSO is functioning properly you will see something similar to the following:
   ```
   ----FSSO logons----
   IP: 10.10.20.3 User: ADMINISTRATOR Groups: CN=FORTIOS WRITERS,CN=USERS,DC=TECHDOC,DC=LOCAL
       Workstation: WIN2K8R2.TECHDOC.LOCAL MemberOf: FortiOS_Writers
   IP: 10.10.20.7 User: TELBAR Groups: CN=FORTIOS WRITERS,CN=USERS,DC=TECHDOC,DC=LOCAL
       Workstation: TELBAR-PC7.TECHDOC.LOCAL
   Total number of logons listed: 2, filtered: 0
   ----end of FSSO logons----
   ```
   The exact information will vary based on your installation.
5. Check the FortiGate event log, for FSSO-auth action or other FSSO related events with FSSO information in the message field.
6. To check server connectivity, run the following commands from the CLI:
   ```
   FGT# diagnose debug enable
   FGT# diagnose debug authd fsso server-status
   FGT# Server Name Connection Status Version
        ----------- ----------------- -------
        techdoc       connected FSSO 5.0.0241
   ```

Troubleshooting FSSO

When installing, configuring, and working with FSSO some problems are quite common. A selection of these problems follows including explanations and solutions.

Some common Windows AD problems include:

- General troubleshooting tips for FSSO
- Users on a particular computer (IP address) cannot access the network
- Guest users do not have access to network
- Can't find the DCagent service
- User logon events not received by FSSO Collector agent
- Mac OS X users can't access external resources after waking from sleep mode

General troubleshooting tips for FSSO

The following tips are useful in many FSSO troubleshooting situations.

- Ensure all firewalls are allowing the FSSO required ports through.
  FSSO has a number of required ports that must be allowed through all firewalls or connections will fail. These include: ports 139, 389 (LDAP), 445, 636 (LDAP) 8000, and 8002.
- Ensure the Collector agent has at least 64kbps bandwidth to the FortiGate unit.
  If not the Collector agent does not have this amount of bandwidth, information FSSO information may not reach

the FortiGate unit resulting in outages. The best solution is to configure traffic shaping between the FortiGate unit and the Collector agent to ensure that minimum bandwidth is always available.

Users on a particular computer (IP address) cannot access the network

Windows AD Domain Controller agent gets the username and workstation where the logon attempt is coming from. If there are two computers with the same IP address and the same user trying to logon, it is possible for the authentication system to become confused and believe that the user on computer_1 is actually trying to access computer_2.

Windows AD does not track when a user logs out. It is possible that a user logs out on one computer, and immediate logs onto a second computer while the system still believes the user is logged on the original computer. While this is allowed, information that is intended for the session on one computer may mistakenly end up going to the other computer instead. The result would look similar to a hijacked session.

Solutions

- Ensure each computer has separate IP addresses.
- Encourage users to logout on one machine before logging onto another machine.
- If multiple users have the same username, change the usernames to be unique.
- Shorten timeout timer to flush inactive sessions after a shorter time.

Guest users do not have access to network

A group of guest users was created, but they don't have access.

Solution

The group of the guest users was not included in a policy, so they do not fall under the guest account. To give them access, associate their group with a security policy.

Additionally, there is a default group called **`SSO_Guest_Users`**. Ensure that group is part of an identity-based security policy to allow traffic.

Can't find the DCagent service

The DCagent service can't be found in the list of regular windows services. This is because it has no associated Windows service.

Instead DCagent is really `dcagent.dll` and is located in the `Windows\system32` folder. This DLL file is loaded when windows boots up and it intercepts all logon events processed by the domain controller to send these events to the Collector agent (CA).

Solution

To verify that the DCagent is installed properly

1. Check that DCagent.dll exists in `Windows\system32` folder.
2. Check that the registry key exists: `[HKEY_LOCAL_MACHINE\SOFTWARE\Fortinet\FSAE\dcagent]`

If both exist, the DCagent is properly installed.

User logon events not received by FSSO Collector agent

When a warning dialog is present on the screen on the Collector agent computer, the Collector agent will not receive any logon events. Once the dialog has been closed normal operation will resume.

If polling mode is enabled, it is possible the polling interval is too large. Use a shorter polling interval to ensure the collector agent is capturing all logon events.

If NetAPI polling mode is enabled, consider switching to Event logs or Event Logs using WMI polling as it provides better accuracy.

Mac OS X users can’t access external resources after waking from sleep mode

When client computers running Mac OS X (10.6.X and higher) wake up from sleep mode, the user must authenticate again to be able to access external resources. If the user does not re-authenticate, the user will maintain access to internal web sites, but will be unable to access any external resources.

This issue is caused by Mac OS X not providing sufficient information to the FSSO. This results in the FortiGate blocking access to the user because they cannot be authenticated.

Solution

The security settings on client computer(s) must be configured to require that a username and password be entered when exiting sleep mode or screen saver. With this feature enabled in Mac OS X, the FortiGate will receive the authentication information it requires to authenticate the user and allow them access.

Note that if the user reverts their settings to disable the password requirement, this will cause the issue to reappear.

SSO using RADIUS accounting records

A FortiGate unit can authenticate users transparently who have already authenticated on an external RADIUS server. Based on the user group to which the user belongs, the security policy applies the appropriate UTM profiles. RADIUS SSO is relatively simple because the FortiGate unit does not interact with the RADIUS server, it only monitors RADIUS accounting records that the server forwards (originating from the RADIUS client). These records include the user's IP address and user group.

After the initial set-up, changes to the user database, including changes to user group memberships, are made on the external RADIUS server, not on the FortiGate unit.

This section describes:

- User's view of RADIUS SSO authentication
- Configuration Overview
- Configuring the RADIUS server
- Creating the FortiGate RADIUS SSO agent
- Defining local user groups for RADIUS SSO
- Creating security policies
- Example: webfiltering for student and teacher accounts

User's view of RADIUS SSO authentication

For the user, RADIUS SSO authentication is simple:

- The user connects to the RADIUS server and authenticates.
- The user attempts to connect to a network resource that is reached through a FortiGate unit. Authentication is required for access, but the user connects to the destination without being asked for logon credentials because the FortiGate unit knows that the user is already authenticated. FortiOS applies UTM features appropriate to the user groups that the user belongs to.

Configuration Overview

The general steps to implement RADIUS Single Sign-On are:

1. If necessary, configure your RADIUS server. The user database needs to include user group information and the server needs to send accounting messages.
2. Create the FortiGate RADIUS SSO agent.
3. Define local user groups that map to RADIUS groups.
4. Create a security policy which specifies the user groups that are permitted access.

Configuring the RADIUS server

You can configure FortiGate RSSO to work with most RADIUS-based accounting systems. In most cases, you only need to do the following to your RADIUS accounting system:

- Add a user group name field to customer accounts on the RADIUS server so that the name is added to the RADIUS Start record sent by the accounting system to the FortiOS unit. User group names do not need to be added for all

users, only to the accounts of users who will use RSSO feature on the FortiGate unit.

- Configure your accounting system to send RADIUS Start records to the FortiOS unit. You can send the RADIUS Start records to any FortiGate network interface. If your FortiGate unit is operating with virtual domains (VDOMs) enabled, the RADIUS Start records must be sent to a network interface in the management VDOM.

Creating the FortiGate RADIUS SSO agent

Once you define a RADIUS SSO (RSSO) agent, the FortiGate unit will accept user logon information from any RADIUS server that has the same shared secret. You can create only one RSSO agent in each VDOM.

Before you create the RSSO agent, you need to allow RADIUS accounting information on the interface that connects to the RADIUS server.

To enable RADIUS access on the interface - web-based manager:

1. Go to **System > Network > Interfaces** and edit the interface to which the RADIUS server connected.
2. Select **Listen for RADIUS Accounting Messages**.
3. Select **OK**.

To enable RADIUS access on the interface - CLI:

In this example, the port2 interface is used.

```
config system interface
   edit port2
      set allowaccess radius-acct
   end
```

To create a RADIUS SSO agent:

1. Go to **User & Device > Authentication > Single Sign-On** and select **Create New**.
2. In **Type**, select **RADIUS Single-Sign-On Agent**.
3. Select **Use RADIUS Shared Secret** and enter the RADIUS server shared secret.
4. Select **Send RADIUS Responses**.
5. Select **OK**.

To create a RADIUS SSO agent - CLI

```
config user radius
   edit RSSO_Agent
      set rsso enable
      set rsso-validate-request-secret enable
      set rsso-secret <your secret>
      set rsso-radius-response enable
   end
```

Selecting which RADIUS attributes are used for RSSO

For RADIUS SSO to work, FortiOS needs to know the user's endpoint identifier (usually IP address) and RADIUS user group. There are default RADIUS attributes where FortiOS expects this information, but you can change these attributes in the `config user radius` CLI command.

RSSO information and RADIUS attribute defaults

RSSO Information	RADIUS Attribute	CLI field
Endpoint identifier	Calling-Station-ID	`rsso-endpoint-attribute`
Endpoint block attribute	Called-Station-ID	`rsso-endpoint-block-attribute`
User group	Class	`sso-attribute`

The Endpoint block attribute can be used to block or allow a user. If the attribute value is set to the name of an attribute that indicates whether to block or allow, FortiOS blocks or allows respectively all traffic from that user's IP address. The RSSO fields are visible only when `rsso` is set to `enable`.

Configuring logging for RSSO

In the `config user radius` CLI command, you can set the following flags in the `rsso-log-flags` field to determine which types of RSSO-related events are logged:

- `protocol-error` — A RADIUS protocol error occurred.
- `profile-missing` — FortiOS cannot find a user group name in a RADIUS start message that matches the name of an RSSO user group in FortiOS.
- `accounting-stop-missed` — a user context entry expired without FortiOS receiving a RADIUS Stop message.
- `accounting-event` — FortiOS did not find the expected information in a RADIUS record.
- `endpoint-block` — FortiOS blocked a user because the RADIUS record's endpoint block attribute had the value "Block".
- `radiusd-other` — Other events, described in the log message.

Defining local user groups for RADIUS SSO

You cannot use RADIUS user groups directly in security policies. Instead, you create locally-defined user groups on the FortiGate unit and associate each of them with a RADIUS user group.

To define local user groups for RADIUS SSO:

1. Go to **User & Device > User > User Groups** and select **Create New**.
2. Enter a Name for the user group.
3. In **Type**, select **RADIUS Single Sign-On (RSSO)**.
4. In **RADIUS Attribute Value**, enter the name of the RADIUS user group this local user group represents.
5. Select **OK**.

To define local user groups for RADIUS SSO:

This example creates an RSSO user group called RSSO-1 that is associated with RADIUS user group "student".

```
config user group
   edit RSSO-1
      set group-type rsso
      set sso-attribute-value student
   end
```

Creating security policies

RADIUS SSO uses regular identity-based security policies. The RSSO user group you specify determines which users are permitted to use the policy. You can create multiple policies if user groups can have different UTM features enabled, different permitted services, schedules, and so on.

To create a security policy for RSSO - web-based manager:

1. Go to **Policy & Objects > Policy > IPv4**.
2. Select **Create New**.
3. Enter the following information.

Incoming Interface	as needed
Source Address	as needed
Source User(s)	Select the user groups you created for RSSO. See Defining local user groups for RADIUS SSO on page 693.
Outgoing Interface	as needed
Destination Address	all
Schedule	as needed
Service	as needed
Action	ACCEPT
Enable NAT	Selected
Security Profiles	Select security profiles appropriate for the user group.

4. Select **OK**.

   To ensure an RSSO-related policy is matched first, the policy should be placed higher in the security policy list than more general policies for the same interfaces.
5. Select **OK**.

To create a security policy for RSSO - CLI:

In this example, an internal network to Internet policy enables web access for members of a student group and activates the appropriate UTM profiles.

```
config firewall policy
   edit 0
      set srcintf internal
      set dstintf wan1
      set srcaddr all
      set dstaddr "all"
      set action accept
      set rsso enable
      set groups "RSSO-student"
      set schedule always
```

```
    set service HTTP HTTPS
    set nat enable
    set utm-status enable
    set av-profile students
    set webfilter-profile students
    set spamfilter-profile students
    set dlp-sensor default
    set ips-sensor default
    set application-list students
    set profile-protocol-options "default"
end
```

Example: webfiltering for student and teacher accounts

The following example uses RADIUS SSO to apply web filtering to students, but not to teachers. Assume that the RADIUS server is already configured to send RADIUS Start and Stop records to the FortiGate unit. There are two RADIUS user groups, **students** and **teachers**, recorded in the default attribute **Class**. The workstations are connected to port1, port2 connects to the RADIUS server, and port3 connects to the Internet.

Configure the student web filter profile:

1. Go to **Security Profiles > Web Filter** and select **Create New** (the "+" button).
2. Enter the following and select **OK**.

Name	student
Inspection Mode	Proxy
FortiGuard Categories	Enable. Right-click the **Potentially Liable** category and select **Block**. Repeat for **Adult/Mature Content** and **Security Risk**.

Create the RADIUS SSO agent:

1. Go to **User & Device > Authentication > Single Sign-On** and select **Create New**.
2. In **Type**, select **RADIUS Single-Sign-On**.
3. Select **Use RADIUS Shared Secret** and enter the RADIUS server shared secret.
4. Select **Send RADIUS Responses**.
5. Select **OK**.

Define local user groups associated with the RADIUS SSO user groups:

1. Go to **User & Device > User > User Groups** and select **Create New**.
2. Enter the following and select **OK**.

Name	RSSO-students
Type	RADIUS Single Sign-On (RSSO)
RADIUS Attribute Value	students

3. Select **Create New**, enter the following and select **OK**.

Name	RSSO-teachers
Type	RADIUS Single Sign-On (RSSO)
RADIUS Attribute Value	teachers

Create a security policy for students:

1. Go to **Policy & Objects > Policy > IPv4** and select **Create New**.
2. Enter

Incoming Interface	port1
Source Address	all
Source User(s)	RSSO-students
Source Device Type	All
Outgoing Interface	port3
Destination Address	all
Schedule	always
Service	HTTP, HTTPS
Action	ACCEPT
NAT	ON
Security Profiles	Enable AntiVirus, Web Filter, IPS. In Web Filter, select the **student** profile.

3. Select **OK**.

Create a security policy for teachers:

1. Go to **Policy & Objects > Policy > IPv4** and select **Create New**.
2. Enter

Incoming Interface	port2
Source Address	all
Source User(s)	RSSO-teachers
Source Device Type	All
Outgoing Interface	port3
Destination Address	all

Schedule	always
Service	ALL
Action	ACCEPT
NAT	ON
Security Profiles	Enable AntiVirus and IPS.

3. Select **OK**.

Monitoring authenticated users

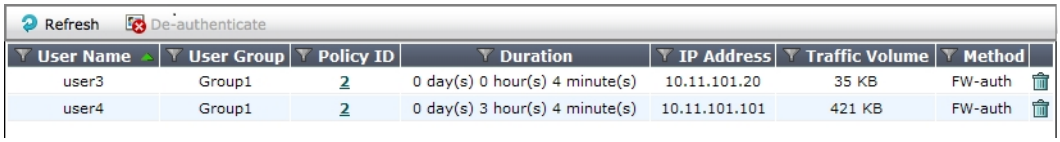
This section describes how to view lists of currently logged-in firewall and VPN users. It also describes how to disconnect users.

The following topics are included in this section:

- Monitoring firewall users
- Monitoring SSL VPN users
- Monitoring IPsec VPN users
- Monitoring users Quarantine

Monitoring firewall users

To monitor firewall users, go to **User & Device > Monitor > Firewall.**



You can de-authenticate a user by selecting the Delete icon for that entry.

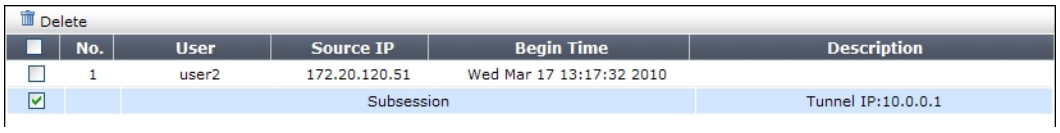
You can filter the list of displayed users by selecting the funnel icon for one of the column titles or selecting **Filter Settings**.

Optionally, you can de-authenticate multiple users by selecting them and then selecting **De-authenticate**.

Monitoring SSL VPN users

You can monitor web-mode and tunnel-mode SSL VPN users by username and IP address.

To monitor SSL VPN users, go to **VPN > Monitor > SSL-VPN Monitor**. To disconnect a user, select the user and then select the **Delete** icon.



The first line, listing the username and IP address, is present for a user with either a web-mode or tunnel-mode connection. The Subsession line is present only if the user has a tunnel mode connection. The **Description** column displays the virtual IP address assigned to the user's tunnel-mode connection.

For more information about SSL VPN, see the FortiOS Handbook SSL VPN guide.

To monitor SSL VPN users - CLI:

To list all of the SSL VPN sessions and their index numbers:

```
execute vpn sslvpn list
```

The output looks like this:

```
SSL-VPN Login Users:
 Index   User   Auth Type   Timeout         From      HTTPS in/out
 0       user1  1           256       172.20.120.51   0/0

SSL-VPN sessions:
 Index   User   Source IP        Tunnel/Dest IP
 0       user2  172.20.120.51    10.0.0.1
```

You can use the Index value in the following commands to disconnect user sessions:

To disconnect a tunnel-mode user

```
execute vpn sslvpn del-tunnel <index>
```

To disconnect a web-mode user

```
execute vpn sslvpn del-web <index>
```

You can also disconnect multiple users:

To disconnect all tunnel-mode SSL VPN users in this VDOM

```
execute vpn ssl del-all tunnel
```

To disconnect all SSL VPN users in this VDOM

```
execute vpn ssl del-all
```

Monitoring IPsec VPN users

To monitor IPsec VPN tunnels in the web-based manager, go to **VPN > Monitor > IPsec Monitor**. user names are available only for users who authenticate with XAuth.

You can close a tunnel by selecting the tunnel and right click to select **Bring Down**.

For more information, see the FortiOS Handbook IPsec VPN guide.

Monitoring users Quarantine

The User Quarantine list shows all IP addresses and interfaces blocked by NAC quarantine. The list also shows all IP addresses, authenticated users, senders, and interfaces blocked by Data Leak Prevention (DLP). The system administrator can selectively release users or interfaces from quarantine or configure quarantine to expire after a selected time period.

All sessions started by users or IP addresses on the User Quarantine list are blocked until the user or IP address is removed from the list. All sessions to an interface on the list are blocked until the interface is removed from the list.

You can configure NAC quarantine to add users or IP addresses to the User Quarantine list under the following conditions:

- **Users or IP addresses that originate attacks detected by IPS** - To quarantine users or IP addresses that originate attacks, enable and configure **Quarantine** in an IPS Filter.
- **Users or IP addresses that are quarantined by Data Leak Prevention** - In a DLP sensor select **Quarantine IP Address** as the action to take.

For more information, see FortiOS Handbook Security Profiles guide.

Users are viewed from **User & Device > Monitor > User Quarantine.**

Delete	Removes the selected user or IP address from the User Quarantine list.
Remove All	Removes all users and IP addresses from the User Quarantine list.
Search	Search the list for a particular IP address.
Source	The FortiGate function that caused the user or IP address to be added to the User Quarantine list: IPS or Data Leak Prevention.
Created	The date and time the user or IP address was added to the Banned User list.
Expires	The date and time the user or IP address will be automatically removed from the User Quarantine list. If **Expires** is **Indefinite**, you must manually remove the user or host from the list.

Examples and Troubleshooting

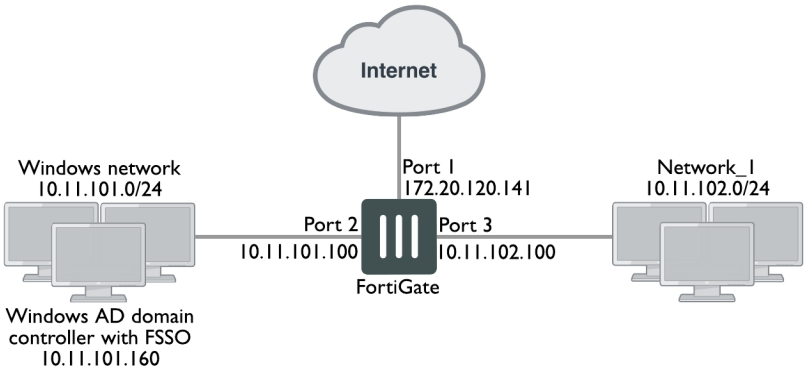
This chapter provides an example of a FortiGate unit providing authenticated access to the Internet for both Windows network users and local users.

The following topics are included in this section:

- Firewall authentication example
- LDAP Dial-in using member-attribute example
- RADIUS SSO example
- Troubleshooting

Firewall authentication example

Example configuration



Overview

In this example, there is a Windows network connected to Port 2 on the FortiGate unit and another LAN, Network_1, connected to Port 3.

All Windows network users authenticate when they logon to their network. Members of the Engineering and Sales groups can access the Internet without entering their authentication credentials again. The example assumes that the Fortinet Single Sign On (FSSO) has already been installed and configured on the domain controller.

LAN users who belong to the Internet_users group can access the Internet after entering their username and password to authenticate. This example shows only two users, User1 is authenticated by a password stored on the FortiGate unit, User2 is authenticated on an external authentication server. Both of these users are referred to as local users because the user account is created on the FortiGate unit.

Creating a locally-authenticated user account

User1 is authenticated by a password stored on the FortiGate unit. It is very simple to create this type of account.

To create a local user - web-based manager:

1. Go to **User & Device > User > User Definition** and select **Create New**.
2. Follow the User Creation Wizard, entering the following information and then select **Create**:

User Type	Local User
User Name	User1
Password	hardtoguess
Email Address **SMS**	(optional)
Enable	Select.

To create a local user - CLI:

```
config user local
   edit user1
      set type password
      set passwd hardtoguess
   end
```

Creating a RADIUS-authenticated user account

To authenticate users using an external authentication server, you must first configure the FortiGate unit to access the server.

To configure the remote authentication server - web-based manager:

1. Go to **User & Device > Authentication > RADIUS Servers** and select **Create New**.
2. Enter the following information and select **OK**:

Name	OurRADIUSsrv
Primary Server Name/IP	10.11.101.15
Primary Server Secret	OurSecret
Authentication Scheme	Select **Use Default Authentication Scheme**.

To configure the remote authentication server - CLI:

```
config user radius
   edit OurRADIUSsrv
      set server 10.11.102.15
      set secret OurSecret
      set auth-type auto
   end
```

Creation of the user account is similar to the locally-authenticated account, except that you specify the RADIUS authentication server instead of the user's password.

To configure a remote user - web-based manager:

1. Go to **User & Device > User > User Definition** and select **Create New**.
2. Follow the User Creation Wizard, entering the following information and then select **Create**:

User Type	Remote RADIUS User
User Name	User2
RADIUS server	OurRADIUSsrv
Email Address **SMS**	(optional)
Enable	Select

To configure a remote user - CLI:

```
config user local
   edit User2
      set name User2
      set type radius
      set radius-server OurRADIUSsrv
   end
```

Creating user groups

There are two user groups: an FSSO user group for FSSO users and a firewall user group for other users. It is not possible to combine these two types of users in the same user group.

Creating the FSSO user group

For this example, assume that FSSO has already been set up on the Windows network and that it uses Advanced mode, meaning that it uses LDAP to access user group information. You need to

- configure LDAP access to the Windows AD global catalog
- specify the collector agent that sends user logon information to the FortiGate unit
- select Windows user groups to monitor
- select and add the Engineering and Sales groups to an FSSO user group

To configure LDAP for FSSO - web-based manager:

1. Go to **User & Device > Authentication > LDAP Servers** and select **Create New**.
2. Enter the following information:

Name	ADserver
Server Name / IP	10.11.101.160
Distinguished Name	dc=office,dc=example,dc=com
Bind Type	Regular

User DN	cn=FSSO_Admin,cn=users,dc=office,dc=example,dc=com
Password	set_a_secure_password

3. Leave other fields at their default values.
4. Select **OK**.

To configure LDAP for FSSO - CLI"

```
config user ldap
   edit "ADserver"
      set server "10.11.101.160"
      set dn "cn=users,dc=office,dc=example,dc=com"
      set type regular
      set username "cn=administrator,cn=users,dc=office,dc=example,dc=com"
      set password set_a_secure_password
   next
end
```

To specify the collector agent for FSSO - web-based manager

1. Go to **User & Device > Authentication > Single Sign-On** and select **Create New.**
2. Enter the following information:

Type	Fortinet Single Sign-On Agent
Name	WinGroups
Primary Agent IP/Name	10.11.101.160
Password	fortinet_canada
LDAP Server	ADserver

3. Select **Apply & Refresh**.

In a few minutes, the FortiGate unit downloads the list of user groups from the server.

To specify the collector agent for FSSO - CLI:

```
config user fsso
   edit "WinGroups"
      set ldap-server "ADserver"
      set password ENC
          G7GQV7NEqilCM9jKmVmJJFVvhQ2+wtNEe9T0iYA5Sa+EqT2J8zhOrbkJFDr0RmY3c4LaoXdsoBczA
          1dONmcGfthTxxwGsigzGpbJdC71spFlQYtj
      set server "10.11.101.160"
   end
```

To create the FSSO_Internet-users user group - web-based manager:

1. Go to **User & Device > User > User Groups** and select **Create New**.
2. Enter the following information and then select **OK**:

Name	FSSO_Internet_users
Type	Fortinet Single Sign-On (FSSO)
Members	Engineering, Sales

To create the FSSO_Internet-users user group - CLI:

```
config user group
   edit FSSO_Internet_users
      set group-type fsso-service
      set member CN=Engineering,cn=users,dc=office,dc=example,dc=com
          CN=Sales,cn=users,dc=office,dc=example,dc=com
   end
```

Creating the Firewall user group

The non-FSSO users need a user group too. In this example, only two users are shown, but additional members can be added easily.

To create the firewall user group - web-based manager:

1. Go to **User & Device > User > User Groups** and select **Create New**.
2. Enter the following information and then select **OK**:

Name	Internet_users
Type	Firewall
Members	User1, User2

To create the firewall user group - CLI:

```
config user group
   edit Internet_users
      set group-type firewall
      set member User1 User2
   end
```

Defining policy addresses

1. Go to **Policy & Objects > Objects > Addresses**.
2. Create the following addresses:

Address Name	Internal_net
Type	Subnet
Subnet / IP Range	10.11.102.0/24
Interface	Port 3

Address Name	Windows_net
Type	Subnet
Subnet / IP Range	10.11.101.0/24
Interface	Port 2

Creating security policies

Two security policies are needed: one for firewall group who connect through port3 and one for FSSO group who connect through port2.

To create a security policy for FSSO authentication - web-based manager:

1. Go to **Policy & Objects > Policy > IPv4** and select **Create New**.
2. Enter the following information:

Incoming Interface	Port2
Source Address	Windows_net
Source User(s)	FSSO_Internet_users
Outgoing Interface	Port1
Destination Address	all
Schedule	always
Service	ALL
NAT	ON
Security Profiles	Optionally, enable security profiles.

3. Select OK.

To create a security policy for FSSO authentication - CLI:

```
config firewall policy
   edit 0
      set srcintf port2
      set dstintf port1
      set srcaddr Windows_net
      set dstaddr all
      set action accept
      set groups FSSO_Internet_users
      set schedule always
      set service ANY
      set nat enable
   end
```

To create a security policy for local user authentication - web-based manager

1. Go to **Policy & Objects > Policy > IPv4** and select **Create New**.
2. Enter the following information:

Incoming Interface	Port3
Source Address	Internal_net
Source User(s)	Internet_users
Outgoing Interface	Port1
Destination Address	all
Schedule	always
Service	ALL
NAT	ON
Security Profiles	Optionally, enable security profiles.

3. Select **OK**.

To create a security policy for local user authentication - CLI

```
config firewall policy
   edit 0
      set srcintf port3
      set dstintf port1
      set srcaddr internal_net
      set dstaddr all
      set action accept
      set schedule always
      set groups Internet_users
      set service ANY
      set nat enable
   end
```

LDAP Dial-in using member-attribute example

In this example, users defined in MicroSoft Windows Active Directory (AD) are allowed to set up a VPN connection simply based on an attribute that is set to TRUE, instead of based on their user group. In AD the "Allow Dialin" property is activated in the user properties, and this sets the `msNPAllowDialin` attribute to "TRUE".

This same procedure can be used for other member attributes, as your system requires.

To accomplish this with a FortiGate unit, member-attribute must be set. This can only be accomplished through the CLI - the option is not available through the web-based manager.

Before configuring the FortiGate unit, ensure the AD server has the `msNPAllowDialin` attribute set to "TRUE" for the users in question. If not, those users will not be able to authenticate.

To configure user LDAP member-attribute settings - CLI:

```
config user ldap
   edit "ldap_server"
      set server "192.168.201.3"
      set cnid "sAMAccountName"
      set dn "DC=fortilabanz,DC=com,DC=au"
      set type regular
      set username "fortigate@sample.com"
      set password ******
      set member-attr "msNPAllowDialin"
   next
end
```

To configure LDAP group settings - CLI:

```
config user group
   edit "ldap_grp"
      set member "ldap"
      config match
         edit 1
            set server-name "ldap"
            set group-name "TRUE"
         next
      end
   next
end
```

Once these settings are in place, users that are a member of the `ldap` user group will be able to authenticate.

To ensure your settings are correct, here is the sample output from a diag debug command that shows the authentication process.

When the "Allow Dial-in" attribute is set to "TRUE" the following will likely be in the output:

```
get_member_of_groups-Get the memberOf groups.
get_member_of_groups- attr='msNPAllowDialin', found 1 values
get_member_of_groups-val[0]='TRUE'
fnbamd_ldap_get_result-Auth accepted
fnbamd_ldap_get_result-Going to DONE state res=0
fnbamd_auth_poll_ldap-Result for ldap svr 192.168.201.3 is SUCCESS
fnbamd_auth_poll_ldap-Passed group matching
```

If the attribute is not set but it is expected, the following will likely be in the output:

```
get_member_of_groups-Get the memberOf groups.
get_member_of_groups- attr='msNPAllowDialin', found 1 values
get_member_of_groups-val[0]='FALSE'
fnbamd_ldap_get_result-Auth accepted
fnbamd_ldap_get_result-Going to DONE state res=0
fnbamd_auth_poll_ldap-Result for ldap svr 192.168.201.3 is SUCCESS
fnbamd_auth_poll_ldap-Failed group matching
```

The only difference between these two outputs is the last line which is either passed or failed based on if the member-attribute is set to the expected value or not.

RADIUS SSO example

A common RADIUS SSO topology involves a medium sized company network of users connecting to the Internet through the FortiGate unit, and authenticating with a RADIUS server. RADIUS SSO authentication was selected because it is fast and relatively easy to configure.

This section includes:

- Assumptions
- Topology
- Configuring RADIUS
- Configuring FortiGate regular and RADIUS SSO security policies
- Testing

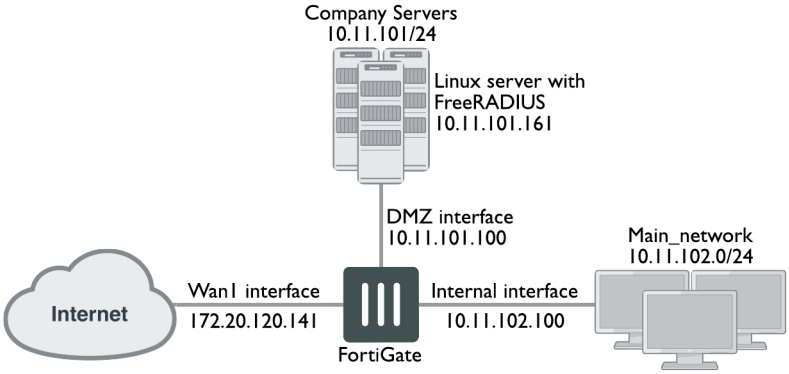
Assumptions

- VDOMs are not enabled
- The admin super_admin administrator account will be used for all FortiGate unit configuration.
- Any other devices on the network do not affect the topology of this example, and therefore are not included.
- Anywhere settings are not described, they are assumed to be default values.
- A RADIUS server is installed on a server or FortiAuthenticator unit and uses default attributes.
- BGP is used for any dynamic routing.
- Authentication event logging under Log&Report has been configured.

Topology

Example.com has an office with 20 users on the internal network. These users need access to the Internet to do their jobs. The office network is protected by a FortiGate-60C unit with access to the Internet through the wan1 interface, the user network on the internal interface, and all the servers are on the DMZ interface. This includes an Ubuntu Linux server running FreeRADIUS. For this example only two users will be configured — Pat Lee with an account name `plee`, or `plee@example.com`, and Kelly Green with an account name `kgreen`, or `kgreen@example.com`.

RADIUS SSO topology



Configuring RADIUS

Configuring RADIUS includes configuring the RADIUS server such as FreeRADIUS, a radius client on user's computers, and configuring users in the system. For this example the two users will be Pat Lee, and Kelly Green. They belong to a group called `exampledotcom_employees`. When it is all configured, the RADIUS daemon needs to started.

The users have a RADIUS client installed on their PCs that allows them to authenticate through the RADIUS server.

FreeRADIUS can be found on the freeradius.org website. For any problems installing FreeRADIUS, see the FreeRADIUS documentation.

Configuring FortiGate interfaces

Before configuring the RADIUS SSO security policy, configure FortiGate interfaces. This includes defining a DHCP server for the internal network as this type of network typically uses DHCP. The wan1 and dmz interfaces are assigned static IP addresses and do not need a DHCP server.

FortiGate interfaces used in this example

Interface	Subnet	Act as DHCP Server	Devices
wan1	172.20.120.141	No	Internet Service Provider
dmz	10.11.101.100	No	Servers, including RADIUS server
internal	10.11.102.100	Yes: x.x.x.110-.250	Internal user network

To configure FortiGate interfaces - web-based manager:

1. Go to **System > Network > Interfaces**.
2. Select wan1 to edit.
3. Enter the following information and select **OK**.

Alias	Internet
Addressing Mode	Manual
IP/Network Mask	172.20.120.141/255.255.255.0
Administrative Access	HTTPS, SSH
Enable DHCP Server	Not selected
Comments	Internet
Administrative Status	Up

4. Select dmz to edit.
5. Enter the following information and select **OK**.

Alias	Servers
Addressing Mode	Manual
IP/Network Mask	10.11.101.100/255.255.255.0
Administrative Access	HTTPS, SSH, PING, SNMP
Enable DHCP Server	Not selected
Listen for RADIUS Accounting Messages	Select
Comments	Servers
Administrative Status	Up

6. Select internal to edit.
7. Enter the following information and select **OK**.

Alias	Internal network
Addressing Mode	Manual
IP/Network Mask	10.11.102.100/255.255.255.0
Administrative Access	HTTPS, SSH, PING
Enable DHCP Server	Select
Address Range	10.11.102.110 - 10.11.102.250
Netmask	255.255.255.0
Default Gateway	Same as Interface IP
DNS Server	Same as System DNS
Comments	Internal network
Administrative Status	Up

Configuring a RADIUS SSO Agent on the FortiGate unit

To create a RADIUS SSO agent:

1. Go to **User & Device > Authentication > Single Sign-On** and select **Create New**.
2. In **Type**, select **RADIUS Single-Sign-On Agent**.
3. Select **Use RADIUS Shared Secret** and enter the RADIUS server shared secret.
4. Select **Send RADIUS Responses**.
5. Select **OK**.
   The Single Sign-On agent is named RSSO_Agent.

Creating a RADIUS SSO user group

To define a local user group for RADIUS SSO:

1. Go to **User & Device > User > User Groups** and select **Create New**.
2. Enter a Name for the user group.
3. In **Type**, select **RADIUS Single Sign-On (RSSO)**.
4. In **RADIUS Attribute Value**, enter the name of the RADIUS user group this local user group represents.
5. Select **OK**.

Configuring FortiGate regular and RADIUS SSO security policies

With the RADIUS server and FortiGate interfaces configured, security policies can be configured. This includes both RADIUS SSO and regular policies, as well as addresses and address groups. All policies require NAT to be enabled.

Security policies required for RADIUS SSO

Seq. No.	From -> To	Type	Schedule	Description
1	internal -> wan1	RADIUS SSO	business hours	Authenticate outgoing user traffic.
2	internal -> wan1	regular	always	Allow essential network services and VoIP.
3	dmz -> wan1	regular	always	Allow servers to access Internet.
4	internal -> dmz	regular	always	Allow users to access servers.
5	any -> any	deny	always	Implicit policy denying all traffic that hasn't been matched.

The RADIUS SSO policy must be placed at the top of the policy list so it is matched first. The only exception to this is if you have a policy to deny access to a list of banned users. In this case, that policy must go at the top so the RADIUS SSO does not mistakenly match a banned user or IP address.

This section includes:

- Schedules, address groups, and services groups
- Configuring regular security policies
- Configuring RADIUS SSO security policy

Schedules, address groups, and services groups

This section lists the lists that need to be configured before security policies are created. Creating these lists is straight forward, so the essential information has been provided here but not step by step instructions. For more

information on firewall related details, see

Schedules

Only one schedule needs to be configured — `business_hours`. This is a fairly standard Monday to Friday 8am to 5pm schedule, or whatever days and hours covers standard work hours at the company.

Address groups

The following address groups need to be configured before the security policies.

Address Group Name	Interface	Address range included
internal_network	internal	10.11.102.110 to 10.11.102.250
company_servers	dmz	10.11.101.110 to 10.11.101.250

Service groups

The following service groups need to be configured before the security policies. Note that the services listed are suggestions and may include more or less as required.

Service Group Name	Interface	Description of services to be included
essential_network_services	internal	Any network protocols required for normal network operation such as DNS, NTP, BGP.
essential_server_services	dmz	All the protocols required by the company servers such as BGP, HTTP, HTTPS, FTP, IMAP, POP3, SMTP, IKE, SQL, MYSQL, NTP, TRACEROUTE, SOCKs, and SNMP.
user_services	internal	Any protocols required by users HTTP, HTTP, FTP,

The following security policy configurations are basic and only include logging, and default AV and IPS.

Configuring regular security policies

Regular security policies allow or deny access for non-RADIUS SSO traffic. This is essential as there are network services—such as DNS, NTP, and FortiGuard—that require access to the Internet.

To configure regular security policies - web-based manager:

1. Go to **Policy & Objects > IPv4 Policy**, and select **Create New**.
2. Enter the following information, and select **OK**.

Incoming Interface	Internal

Source Address	internal_network
Outgoing Interface	wan1
Destination Address	all
Schedule	always
Service	essential_network_services
Action	ACCEPT
NAT	ON
Security Profiles	ON: AntiVirus, IPS
Log Allowed Traffic	ON
Comments	Essential network services

3. Select **Create New**, enter the following information, and select **OK**.

Incoming Interface	dmz
Source Address	company_servers
Outgoing Interface	wan1
Destination Address	all
Schedule	always
Service	essential_server_services
Action	ACCEPT
NAT	ON
Security Profiles	ON: AntiVirus, IPS
Log Allowed Traffic	enable
Comments	Company servers accessing the Internet

4. Select **Create New**, enter the following information, and select **OK**.

Incoming Interface	Internal
Source Address	internal_network
Outgoing Interface	dmz
Destination Address	company_servers

Schedule	always
Service	all
Action	ACCEPT
NAT	ON
Security Profiles	ON: AntiVirus, IPS
Log Allowed Traffic	enable
Comments	Access company servers

Configuring RADIUS SSO security policy

The RADIUS SSO policy allows access for members of specific RADIUS groups.

To configure RADIUS SSO security policy:

1. Go to **Policy & Objects > IPv4 Policy**.
2. Select **Create New**.
3. Enter the following information:

Incoming Interface	Internal
Source Address	internal_network
Source User(s)	Select the user groups you created for RSSO.
Outgoing Interface	wan1
Destination Address	all
Schedule	business_hours
Service	ALL
Action	ACCEPT
NAT	ON
Security Profiles	ON: AntiVirus, WebFilter, IPS, and Email Filter. In each case, select the default profile.

4. Select **OK**.
5. To ensure an RSSO-related policy is matched first, the policy should be placed higher in the security policy list than more general policies for the same interfaces.
6. Select **OK**.

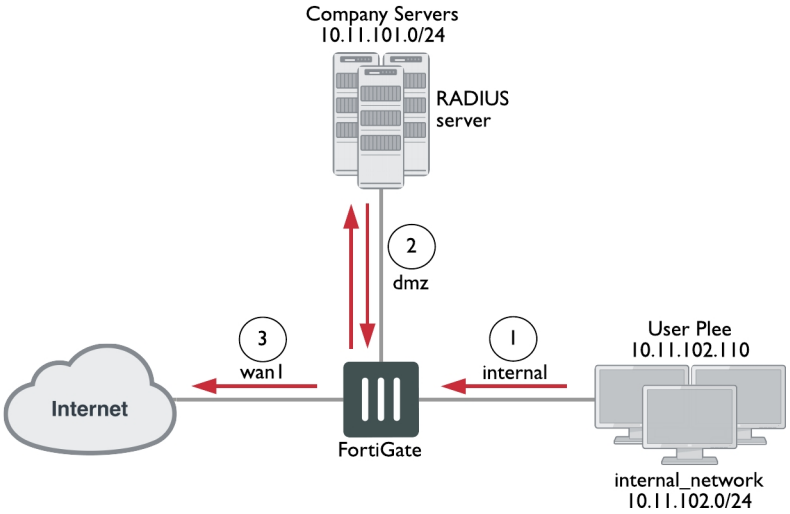
Testing

Once configured, a user only needs to log on to their PC using their RADIUS account. After that when they attempt to access an Internet website, the FortiGate unit will use their session information to get their RADIUS information. Once the user is verified, they are allowed access to the website.

To test the configuration perform the following steps:

1. Have user 'plee' logon to their PC, and try to access an Internet website.
2. The FortiGate unit will contact the RADUS server for user plee's information.
   Once confirmed, plee will have access to the website.
   Each step generates log entries that enable you to verify that each step was successful.
3. If a step is unsuccessful, confirm that your configuration is correct.

RADIUS SSO test



Troubleshooting

In the web-based manager, a good tool for troubleshooting is the packet counter column on the security policy page (**Policy > Policy**). This column displays the number of packets that have passed through this security policy. Its value when you are troubleshooting is that when you are testing your configuration (end to end connectivity, user authentication, policy use) watching the packet count for an increase confirms any other methods you may be using for troubleshooting. It provides the key of which policy is allowing the traffic, useful information if you expect a user to require authentication and it never happens. For more information about authentication security policies, see "Authentication in security policies".

This section addresses how to get more information from the CLI about users and user authentication attempts to help troubleshoot failed authentication attempts.

```
diag firewall iprope list
```

Shows the IP that the computer connected from. This is useful to confirm authorization and VPN settings.

```
diag firewall iprope clear
```

Clear all authorized users from the current list. Useful to force users to re-authenticate after system or group changes. However, this command may easily result in many users having to re-authenticate, so use carefully.

```
diag rsso query ip
diag rsso query rsso-key
```

Queries the RSSO database.

For more information on troubleshooting specific features, go to that section of this document. Most sections have troubleshooting information at the end of the section. In addition to that information, see the FortiOS Handbook Troubleshooting guide for general troubleshooting information.

Chapter 5 - Best Practices

Introduction

This FortiGate Best Practices document is a collection of guidelines to ensure the most secure and reliable operation of FortiGate units in a customer environment. It is updated periodically as new issues are identified.

General Considerations

1. For security purposes, NAT mode is preferred because all of the internal or DMZ networks can have secure private addresses. NAT mode policies use network address translation to hide the addresses in a more secure zone from users in a less secure zone.
2. Use virtual domains (VDOMs) to group related interfaces or VLAN subinterfaces. Using VDOMs will partition networks and create added security by limiting the scope of threats.
3. Use Transparent mode when a network is complex and does not allow for changes in the IP addressing scheme.

Customer service and technical support

For antivirus and attack definition updates, firmware updates, updated product documentation, technical support information, and other resources, please visit the Fortinet Technical Support web site at http://support.fortinet.com.

You can also register Fortinet products and service contracts from http://support.fortinet.com and change your registration information at any time.

For information about our priority support hotline (live support), see http://support.fortinet.com.

When requesting technical support, please provide the following information:

- Your name, and your company's name and location
- Your email address and/or telephone number
- Your support contract number (if applicable)
- The product name and model number
- The product serial number (if applicable)
- The software or firmware version number
- A detailed description of the problem

Fortinet Knowledge Base

The most recent Fortinet technical documentation is available from the Fortinet Knowledge Base. The knowledge base contains short how-to articles, FAQs, technical notes, product and feature guides, and much more. Visit the Fortinet Knowledge Base at http://kb.fortinet.com.

Comments on Fortinet technical documentation

Please send information about any errors or omissions in this document, or any Fortinet technical documentation, to techdoc@fortinet.com.

System and performance

By implementing the following best practices for system and performance, you will ensure maximum efficiency of your FortiGate device. Be sure to read everything carefully, particularly the section that concerns shutting down the FortiGate system, in order to avoid potential hardware issues.

Performance

- Disable any management features you do not need. If you don't need SSH or SNMP, disable them. SSH also provides another possibility for would-be hackers to infiltrate your FortiGate unit.
- Put the most used firewall rules to the top of the interface list.
- Log only necessary traffic. The writing of logs, especially if to an internal hard disk, slows down performance.
- Enable only the required application inspections.
- Keep alert systems to a minimum. If you send logs to a syslog server, you may not need SNMP or email alerts, making for redundant processing.
- Establish scheduled FortiGuard updates at a reasonable rate. Daily updates occurring every 4-5 hours are sufficient for most situations. In more heavy-traffic situations, schedule updates for the evening when more bandwidth can be available.
- Keep security profiles to a minimum. If you do not need a profile on a firewall rule, do not include it.
- Keep VDOMs to a minimum. On low-end FortiGate units, avoid using them if possible.
- Avoid traffic shaping if you need maximum performance. Traffic shaping, by definition, slows down traffic.

Shutting down

Always shut down the FortiGate operating system properly before turning off the power switch to avoid potentially catastrophic hardware problems.

To power off the FortiGate unit - web-based manager:

1. Go to **Dashboard**.
2. In the **System Resources** widget, select **Shutdown**.

To power off the FortiGate unit – CLI:

```
execute shutdown
```

Once this has been done, you can safely turn off the power switch or disconnect the power cables from the power supply.

Migration

Network administrators are often reluctant to change firewall vendors due to the perception that the migration process is difficult. Indeed, there is no point hiding the fact that moving to a new vendor requires careful consideration. But concern over the potential pain of migration should not stand in the way of adopting new security technologies. The purpose of this chapter is to describe the best practices for performing such migrations and ultimately to ease the migration process itself.

Information gathering

It is always best practice to perform a full network audit prior to any migration. This should include:

- Full back up of all security systems (including switches, routers) in case a back-out needs to be performed.
- Physical and logical network diagram with visual audit

Understanding exactly where cables run in the network and verifying they are all correctly labeled is essential to avoid mistakes and unnecessary downtime during the upgrade. Don't overlook simple things such as:

- Do I have enough spare interfaces on my switches?
- Do I have the right fiber (single/multi mode) and right connectors (LC, FC, MTRJ, SC, ST)?
- Do I have spare cables? (in the heat of the moment, it is a simple mistake to break an RJ-45 connector or damage a fiber)
- Do I have space in the rack for the new equipment?
- Do I have enough power sockets?

No matter how securely a FortiGate is configured in the network, it cannot help if it has been bypassed; visually checking where the device sits in the network in relation to other devices will ensure you are maintaining security and verify the network diagram is 'as built'. Details of all networks including subnet masks should be documented at this point to ensure that the replacement device is configured with the correct information.

Object and policy migration

Whilst we have suggested some level of manual review is included in the policy migration, it can be useful to be able to automatically migrate simply between another vendor's format and the FortiGate format. The FortiGate policy format is text based and can easily be cut and pasted into from other vendor formats however, responding to the high customer demand to migrate away from other vendors, Fortinet have released an automatic configuration migration tool at http://convert.fortinet.com to simplify this process. Supporting Cisco ACLs, PIX, ASA, Check Point, and Juniper, the Converter can securely upload and convert the policy into the Fortinet format.

Testing and validation

This is an important process and should be tested offline first wherever possible i.e. configure the policy in the lab or on a test network and verify that the required access permissions are being implemented. To really test the solution out, the FortiGate can be implemented on the live network with a different gateway IP and the selected user pointed to the new gateway. This allows a staged approach to migrating the new platform into the network ensuring that the process does not interrupt day to day operations.

Going live and obtaining feedback

If testing and validation is successful at this point, you can migrate to the new firewall either by switching IP's and removing the old devices or by changing the default gateway in DHCP. Once the firewall is in place, acceptance testing will of course need to be carried out and an iterative process of tuning undertaken to finalize the configuration.

Adding new services

The Fortinet solution will have a plethora of additional features compared to your previous vendor and it is very tempting to start switching them on but it is a good idea to wait and validate the new firewall as was previously configured before adding new functions as this simplifies testing and problem diagnosis. Finally complete the migration (don’t forget about the Plan Do Check Act Cycle) by adding any new services that were requested and learn about the multiple features you have available with the FortiGate appliance.

Environmental specifications

Keep the following environmental specifications in mind when installing and setting up your FortiGate unit.

- Operating temperature: 32 to 104°F (0 to 40°C). Temperatures may vary, depending on the FortiGate model.
- If you install the FortiGate unit in a closed or multi-unit rack assembly, the operating ambient temperature of the rack environment may be greater than room ambient temperature.
  Therefore, make sure to install the equipment in an environment compatible with the manufacturer's maximum rated ambient temperature.
- Storage temperature: -13 to 158°F (-25 to 70°C). Temperatures may vary, depending on the FortiGate model.
- Humidity: 5 to 90% non-condensing.
- Air flow - For rack installation, make sure that the amount of air flow required for safe operation of the equipment is not compromised.
- For free-standing installation, make sure that the appliance has at least 1.5 in. (3.75 cm) of clearance on each side to allow for adequate air flow and cooling.

Depending on your device, the FortiGate may generate, use, and even radiate radio frequency energy and, if not installed and used in accordance with the instructions, may cause harmful interference to radio communications. However, there is no guarantee that interference will not occur in a particular installation. If the equipment does cause harmful interference to radio or television reception, which can be determined by turning the equipment off and on, the user is encouraged to try to correct the interference by one or more of the following measures:

- Reorient or relocate the receiving antenna.
- Increase the separation between the equipment and receiver.
- Connect the equipment into an outlet on a circuit different from that to which the receiver is connected.
- Consult the dealer or an experienced radio/TV technician for help.

Explosion is a serious risk if the battery is replaced by an incorrect type. Dispose of used batteries according to the instructions. To reduce the risk of fire, use only No. 26 AWG or larger UL Listed or CSA Certified Telecommunication Line Cord.

Grounding

- Ensure the FortiGate unit is connected and properly grounded to a lightning and surge protector. WAN or LAN connections that enter the premises from outside the building should be connected to an Ethernet CAT5 (10/100 Mb/s) surge protector.
- Shielded Twisted Pair (STP) Ethernet cables should be used whenever possible rather than Unshielded Twisted Pair (UTP).
- Do not connect or disconnect cables during lightning activity to avoid damage to the FortiGate unit or personal injury.

Rack mounting

- **Elevated Operating Ambient** - If installed in a closed or multi-unit rack assembly, the operating ambient temperature of the rack environment may be greater than room ambient.
  Therefore, consideration should be given to installing the equipment in an environment compatible with the maximum ambient temperature (Tmax) specified by the manufacturer.

- **Reduced Air Flow** - Installation of the equipment in a rack should be such that the amount of air flow required for safe operation of the equipment is not compromised.
- **Mechanical Loading** - Mounting of the equipment in the rack should be such that a hazardous condition is not achieved due to uneven mechanical loading.
- **Circuit Overloading** - Consideration should be given to the connection of the equipment to the supply circuit and the effect that overloading of the circuits might have on overcurrent protection and supply wiring. Appropriate consideration of equipment nameplate ratings should be used when addressing this concern.
- **Reliable Earthing** - Reliable earthing of rack-mounted equipment should be maintained.

Particular attention should be given to supply connections other than direct connections to the branch circuit (e.g. use of power strips).

Firmware

Firmware upgrading and downgrading sounds pretty simple, anyone can do it, right? The mark of a professional is not that they can do something correctly, or even do it correctly over and over again. A professional works in such a way that, if anything goes wrong they are prepared and able to quickly get things back to normal. Firmware updates can go wrong just like anything else. So a real professional does things in a way that minimizes their risk and follows some best practices, as listed below.

Firmware change management

Consider the following five points when performing firmware upgrades, not only in FortiOS but in general. This applies to pretty much any change you have to do in a production environment.

Understanding the new version first

Before attempting any changes in production, first make sure you set up a laboratory where you can freely play with the new features, and understand them with enough time and no pressure. Read the Release Notes, Manuals, and other documentation like presentations, videos, or podcasts about the new version.

You are ready to explain the need for an upgrade once you understand:

- The differences and the enhancements between the new version and the previous version(s).
- The impact of the upgrade on customers and the users of the operating platform.
- The known limitations that might affect your environment.
- The potential risks when performing the upgrade.
- The licensing changes that may apply.

Never attempt to upgrade to a version you don't fully understand (both on features and known limitations), and on which you have no operational experience.

Have a valid reason to upgrade

The reason can NOT be “Because I want to have the latest version”. The reason has to be explained in terms of business, technical, and/or operational improvement.

Affirmative answers to the following questions are valid reasons to upgrade:

- Does the new version have a feature that helps to ensure compliance?
- Does the new version have an enhancement that allows 40% decrease (40% improvement) on the time to perform a certain operation?
- Does the new feature correct a known defect/bug found on a previous version that affects the company business/operations?
- Will the new version allow your organization to deploy new services that will help to gain new customers or increase loyalty of existing ones?
- Is the vendor cutting support for the version your organization is currently using?

If the best reason to upgrade is “Because the new features seem to be cool” or “Because I want to have the latest version”, a little more understanding and planning may be necessary.

Prepare an upgrade plan

If you choose to upgrade because you found a valid reason to do so, make sure you create a plan that covers business, technical, and operational aspects of the upgrade:

Business:

Proper planning and justification for an upgrade should be proportional to how critical the system is to the business.

- Make sure you can clearly articulate the benefits of the upgrade in business terms (time, money, and efficiency).
- Understand the business processes that will be affected by the change.
- Make sure the upgrade maintenance window is not close to a business-critical process (such as quarterly or monthly business closure).
- Obtain executive and operational approval for the maintenance window. The approval must come from the owners of ALL the systems/information affected by the upgrade, not only from those that own the system being upgraded. The approval must be done in a formal (written or e-mail) form.

Technical and operational:

- Re-read the Release Notes for the technology you are upgrading. Supported hardware models, upgrade paths, and known limitations should be clearly understood.
- Make sure your upgrade maintenance window does not overlap with any other maintenance window on your infrastructure.
- If you have any premium support offer (such as TAM, Premium Support), do a capacity planning exercise to ensure the new firmware/software version does not take more hardware resources than you currently have.
- Create a backup, whether or not you have scheduled backups. Create a new fresh backup.
- Obtain offline copies of both the currently installed firmware and the new version.
- Create a list of systems with inter-dependencies to the system you are upgrading. For example, if you are upgrading a FortiGate; understand the impact on any FortiAP, FortiAuthenticator, FortiToken, FortiManager, or FortiAnalyzer you have on your environment.
- Ensure you have a list of adjacent devices to the upgrading platform and have administrative access to them, just in case you need to do some troubleshooting. Are you upgrading FortiWeb? Make sure you can administratively access the Web Applications. Are you upgrading a FortiGate? Make sure you can administratively access the surrounding switches and routers.
- Have a step-by-step plan on how to perform and test the upgrade. You want to make sure you think of the worst situation before it happens, and have predefined courses of action, instead of thinking under pressure when something already went wrong.
- Define a set of tests (that include critical business applications that should be working) to make sure the upgrade went fine. If any test does not go well, define which ones mandate a rollback and which ones can be tolerated for further troubleshooting. This set of tests should be run before and after the upgrade to compare results, and they should be the same.
- Define a clear rollback plan. If something goes wrong with the upgrade or the tests, the rollback plan will help you get your environment back to a known and operational status. The plan must clearly state the conditions under which the rollback will be started.

- Declare configuration freezes. A little bit before and after the upgrade. The idea is to reduce the amount of variables to take into consideration if something goes wrong.
- Perform a “Quality Assurance” upgrade. Grab a copy of the production configuration, load it on a non-production box and execute the upgrade there to see if there are any issues on the process. Then adjust your plan according to the results you obtained.
- Have a list of information elements to be gathered if something goes wrong. This ensures that, even if the upgrade fails, you will collect enough information so you can troubleshoot the issue without needing to repeat the problem. Get help from TAC/Support departments if you need to check what else could be missing on your list.
- Define a test monitoring period after the change was completed. Even if the upgrade went smoothly, something could still go wrong. Make sure you monitor the upgraded system for at least one business cycle. Business cycles may be a week, a month, or a quarter, depending on your organization’s business priorities.

Execute the upgrade plan

Execution of an upgrade is just as key as planning.

Once you are performing the upgrade, the pressure will rise and stress might peak. This is why you should stick to the plan you created with a cool head.

Resist the temptation to take decisions while performing the upgrade, as your judgment will be clouded by the stress of the moment, even if a new decision seems to be “obvious” at such time. If your plan says you should rollback, then execute the rollback despite the potential “We-can-fix-this-very-quickly” mentality.

While performing the upgrade, make sure all the involved components are permanently monitored before, during, and after the upgrade, either via monitoring systems, SNMP alerts, or at least with tools like a ping. Critical resources like CPU, memory, network, and/or disk utilization must also be constantly monitored.

To avoid misunderstandings, when performing the tests for each critical application defined on the planning, make sure there are formal notifications on the results for each user area, service, system, and/or application tested.

Regardless if you have to rollback or not, if a problem occurs, make sure you gather as much information about the problem as possible, so you can later place a support ticket to find a solution.

Last but not least, document the upgrade:

- Enable your terminal emulation program to leave trace of all the commands executed and all the output generated. If you are performing steps via GUI, consider using a video capture tool to document it.
- Document any command or change performed over the adjacent/interdependent systems. Make sure they are acknowledged by the relevant administrators
- Document any deviations performed over the upgrade plan. This is planned-versus-actual.

Learn more about change management

Change Management and Change Control are huge knowledge areas in the field of Information Systems and Computer/Network Security.

This document is by no means a comprehensive list on what you should do when performing an upgrade, with either Fortinet or any other technology. It is merely a list of important things you should take into consideration when performing upgrades which are the result of years of experience dealing with changes on critical environments, as it is common that security devices are protecting critical applications and processes.

There are vast resources on the topic: books, public white papers, blog entries, etc. If you search the Internet for the “Change Control Best Practices” or “Change Management Best Practices” you will get many interesting documents.

Changes on production IT infrastructure are critical to the business. Make sure they play in your favor and not against you.

Performing a firmware upgrade

Upgrading a firewall is something that should be compared to upgrading the operating system on your computer. It’s not to be taken lightly! You want to make sure everything is backed up and you have some options available if things go awry. Assuming it all seems to work you also want a list of things to do in order to confirm everything is working properly. Finally, you need enough time to do it. All really simple stuff, but what does this mean in relation to upgrading your FortiGate? It means, you follow these simple steps:

1. **Backup and store old configuration (full configuration backup from CLI).**
   Digging into this a little, step 1 is easy to understand. Do a full backup of your old configuration. This is all part of your disaster recovery plan. If the upgrade fails in some way you need to make sure you can get the Firewall back up and running. The best way to do this is to get it back to a state where you know what the behavior was. For more information, refer to "Performing a configuration backup" on page 729.
2. **Have copy of old firmware available.**
   Step 2, is also part of your disaster recovery. If the upgrade fails you might be able to switch the active partition. But as a Professional, you need to be prepared for the worst case scenario where you can’t do that. Which means you’ll need your old firmware.
3. **Have disaster recovery option on standby -- especially if remote.**
   Step 3, is your plan for what to do in the event of a critical failure. As we’re talking FortiGate this means that your firewall doesn’t come back after the upgrade. What this means is that you need to be able to get to the console port in order to find out why. Maybe it’s DHCP and the IP changed, maybe the OS is corrupt, who knows? Get to the console and find out.
   There could be a simple fix. If there’s not, then be prepared for a format and TFTP reload.
4. **Read the release notes, including the upgrade path and bug information.**
   Step 4, READ THE RELEASE NOTES. They contain all kinds of information, known bugs, fixed bugs even upgrade issues like lost configuration settings. Not all upgrade information is ever contained in any products release notes. That does not mean they are devoid of good/useful information. Read them, digest them, then a few days later read them again.
5. **Double check everything.**
   Step 5, do a double check of everything. Is your TFTP server working, does your console connection function, is there anything in the release notes that could impact your upgrade procedure, do you have your configuration backed up? Make sure you’ve done everything.
6. **Upgrade.**
   Step 6, do the upgrade. Doing an upgrade doesn’t take very long, a few minutes (less a lot of times) but make sure you schedule enough time for it. At the end of the day an upgrade can succeed or fail. If it succeeds you want some time to check/confirm that any important features you have are working (VPNs etc). If it fails you’ll need time to sort things out.

Performing a firmware downgrade

Just like upgrading, you need to make sure it's done properly. While similar, the steps are somewhat different since there are other pitfalls in this case.

1. **Locate pre-upgrade configuration file.**
   Step 1 is very important. This is why, when you upgrade you make a backup of your old configuration and save it. If you don't, then you'll need to rebuild manually.
2. **Have copy of old firmware available.**
   Step 2 is fairly obvious. Even with devices that have multiple partitions and your downgrade process is simply going to be to switch the active partition, this could go wrong. In which case, you may be without Internet access. A professional has a plan for when things go wrong.
3. **Have disaster recovery option on standby -- especially if remote.**
   Step 3 is no different from before. Hopefully you don't need to format the unit, but be prepared for that, just in case.
4. **Read the release notes -- is a downgrade possible, or necessary?**
   Step 4, once again, is to READ THE RELEASE NOTES. In this case, you will need to do this for the version you are on, and the version you are downgrading too, and everything in between (if you are going back multiple major releases or patches). Maybe the OS switched from 32 to 64 bits somewhere between the two firmware releases. In order to make sure you don't get nailed by something like that you need to check the upgrade and downgrade information in every major release and patch, as it may have a direct impact on your options.
5. **Double check everything.**
6. **Downgrade -- all settings, except those needed for access, are lost.**
   Step 5 and 6 are the same as before. Double check everything, then downgrade.
7. **Restore pre-upgrade configuration.**
   Step 7 is new. Obviously most settings are lost when you downgrade so in order to get back up and running you will need to restore your old configuration file.

Performing a configuration backup

Once you configure the FortiGate unit and it is working correctly, it is extremely important that you backup the configuration. In some cases, you may need to reset the FortiGate unit to factory defaults or perform a TFTP upload of the firmware, which will erase the existing configuration. In these instances, the configuration on the device will have to be recreated, unless a backup can be used to restore it.

It is also recommended that once any further changes are made that you backup the configuration immediately, to ensure you have the most current configuration available. Also, ensure you backup the configuration before upgrading the FortiGate unit's firmware. Should anything happen during the upgrade that changes the configuration, you can easily restore the saved configuration.

Always backup the configuration and store it on the management computer or off-site. You have the option to save the configuration file to various locations including the local PC, USB key, FTP and TFTP site.The latter two are configurable through the CLI only.

If you have VDOMs, you can back up the configuration of the entire FortiGate unit or only a specific VDOM. Note that if you are using FortiManager or FortiCloud, full backups are performed and the option to backup individual VDOMs will not appear.

To back up the FortiGate configuration - web-based manager:

1. Go to **Dashboard**.
2. On the **System Information** widget, select **Backup** next to **System Configuration**.
3. Select to backup to your **Local PC** or to a **USB Disk**.
   The **USB Disk** option will be grayed out if no USB drive is inserted in the USB port. You can also backup to the FortiManager using the CLI.
4. If VDOMs are enabled, select to backup the entire FortiGate configuration (**Full Config**) or only a specific VDOM configuration (**VDOM Config**).
5. If backing up a VDOM configuration, select the VDOM name from the list.
6. Select **Encrypt configuration file**.
   Encryption must be enabled on the backup file to back up VPN certificates.
7. Enter a password and enter it again to confirm it. You will need this password to restore the file.
8. Select **Backup**.
9. The web browser will prompt you for a location to save the configuration file. The configuration file will have a .conf extension.

To back up the FortiGate configuration - CLI:

```
execute backup config management-station <comment>
```

… or …

```
execute backup config usb <backup_filename> [<backup_password>]
```

… or for FTP (note that port number, username are optional depending on the FTP site)…

```
execute backup config ftp <backup_filename> <ftp_server> [<port>] [<user_name>]
    [<password>]
```

… or for TFTP …

```
execute backup config tftp <backup_filename> <tftp_servers> <password>
```

Use the same commands to backup a VDOM configuration by first entering the commands:

```
config vdom
   edit <vdom_name>
```

Backing up a configuration file using SCP

You can use secure copy protocol (SCP) to download the configuration file from the FortiGate unit as an alternative method of backing up the configuration file or an individual VDOM configuration file. This is done by enabling SCP for and administrator account and enabling SSH on a port used by the SCP client application to connect to the FortiGate unit. SCP is enabled using the CLI commands:

```
config system global
   set admin-scp enable
end
```

Use the same commands to backup a VDOM configuration by first entering the commands:

```
config global
   set admin-scp enable
end
```

```
config vdom
   edit <vdom_name>
```

Security Profiles (AV, Web Filtering etc.)

Infection can come from many sources and have many different effects. Because of this, there is no single means to effectively protect your network. Instead, you can best protect your network with the various UTM tools your FortiGate unit offers.

Firewall

- Be careful when disabling or deleting firewall settings. Changes that you make to the firewall configuration using the GUI or CLI are saved and activated immediately.
- Arrange firewall policies in the policy list from more specific to more general. The firewall searches for a matching policy starting from the top of the policy list and working down. For example, a very general policy matches all connection attempts. When you create exceptions to a general policy, you must add them to the policy list above the general policy.
- Avoid using the All selection for the source and destination addresses. Use addresses or address groups.
- If you remove all policies from the firewall, there are no policy matches and all connections are dropped.
- If possible, avoid port ranges on services for security reasons.
- The settings for a firewall policy should be as specific as possible. Do not use 0.0.0.0 as an address. Do not use Any as a service. Use subnets or specific IP addresses for source and destination addresses and use individual services or service groups.
- Use a 32-bit subnet mask when creating a single host address (for example, 255.255.255.255).
- Use logging on a policy only when necessary and be aware of the performance impact. For example, you may want to log all dropped connections but can choose to use this sparingly by sampling traffic data rather than have it continually storing log information you may not use.
- It is possible to use security policies based on 'any' interface. However, for better granularity and stricter security, explicit interfaces are recommended.
- Use the comment field to input management data, for example: who requested the rule, who authorized it, etc.
- Avoid FQDN addresses if possible, unless they are internal. It can cause a performance impact on DNS queries and security impact from DNS spoofing.
- For non vlan interfaces, use zones (even if you have only one single interface for members) to allow:
  - An explicit name of the interface to use in security policies ('internal' is more explicit than 'port10').
  - A split between the physical port and its function to allow port remapping (for instance moving from a 1G interface to a 10G interface) or to facilitate configuration translation, as performed during hardware upgrades.

Security

- Use NTP to synchronize time on the FortiGate and the core network systems, such as email servers, web servers, and logging services.
- Enable log rules to match corporate policy. For example, log administration authentication events and access to systems from untrusted interfaces.
- Minimize adhoc changes to live systems, if possible, to minimize interruptions to the network. When not possible, create backup configurations and implement sound audit systems using FortiAnalyzer and FortiManager.
- If you only need to allow access to a system on a specific port, limit the access by creating the strictest rule possible.

Authentication

- You must add a valid user group to activate the Authentication check box on the firewall policy configuration page.
- Users can authenticate with the firewall using HTTP or FTP. For users to be able to authenticate, you must add an HTTP or FTP policy that is configured for authentication.

Antivirus

- Enable antivirus scanning at the network edge for all services.
- Use FortiClient endpoint antivirus scanning for protection against threats that get into your network.
- Subscribe to FortiGuard AntiVirus Updates and configure your FortiGate unit to receive push updates. This will ensure you receive antivirus signature updates as soon as they are available.
- To ensure that all AV push updates occur, ensure you have an AV profile enabled in a security policy.
- Enable only the protocols you need to scan. If you have antivirus scans occurring on the SMTP server, or use FortiMail, it is redundant to have scanning occur on the FortiGate unit as well.
- Reduce the maximum file size to be scanned. Viruses usually travel in small files of around 1 to 2 megabytes.
- Do not quarantine files unless you regularly monitor and review them. This is otherwise a waste of space and impacts performance.
- Examine antivirus reports and log messages periodically. Take particular notice of repeated detections. For example, repeated virus detection in SMTP traffic could indicate a system on your network is infected and is attempting to contact other systems to spread the infection using a mass mailer.

Antispam

- If possible use, a FortiMail unit. The antispam engines are more robust.
- Use fast DNS servers.
- Use specific security profiles for the rule that will use antispam.
- DNS checks may cause false positive with HELO DNS lookup.
- Content analysis (banned words) may impose performance overhead.

Intrusion Prevention System (IPS)

Your FortiGate's IPS system can detect traffic attempting to exploit this vulnerability. IPS may also detect when infected systems communicate with servers to receive instructions. Refer to the following list of best practices regarding IPS.

- Enable IPS scanning at the network edge for all services.
- Use FortiClient endpoint IPS scanning for protection against threats that get into your network.
- Subscribe to FortiGuard IPS Updates and configure your FortiGate unit to receive push updates. This will ensure you receive IPS signature updates as soon as they are available.
- Because it is critical to guard against attacks on services that you make available to the public, configure IPS signatures to block matching signatures. For example, if you have a web server, configure the action of web server signatures to Block.
- Create and use security profiles with specific signatures and anomalies you need per-interface and per-rule.
- Do not use predefined or generic profiles. While these profiles are convenient to supply immediate protection, you should create profiles to suit your network environment.

- If you do use the default profiles, reduce the IPS signatures/anomalies enabled in the profile to conserve processing time and memory.
- If you are going to enable anomalies, make sure you tune thresholds according to your environment.
- If you need protection, but not audit information, disable the logging option.
- Tune the IP-protocol parameter accordingly.

Blocking Skype using CLI options for improved detection

If you want to identify or block Skype sessions, use the following CLI command with your FortiGate's public IP address to improve detection (FortiOS 4.3.12+ and 5.0.2+):

```
config ips global
   set skype-client-public-ipaddr 198.51.100.0,203.0.113.0
end
```

Note that the above syntax is configured using multiple public IP addresses, where a single public IP address may suffice depending on your network configuration.

Email filter

Spam is a common means by which attacks are delivered. Users often open email attachments they should not, and infect their own machine.

- Enable email filtering at the network edge for all types of email traffic.
- Use FortiClient endpoint IPS scanning for protection against threats that get into your network.
- Subscribe to the FortiGuard AntiSpam Service.

URL filtering

Best practices for URL filtering can be divided into four categories: flow-based versus proxy based filtering; local category/rating feature; URL filter 'Exempt' action; and Deep Scan.

Flow-based versus proxy-based

Try to avoid mixing flow-based and proxy-based features in the same profile if you are not using IPS or Application Control.

Local category/rating feature

Local categories and local rating features consume a large amount of CPU resources, so use these features as little as possible. It is better to use Local categories instead of using the 'override' feature, since the 'override' feature is more complicated and more difficult to troubleshoot.

URL filter 'Exempt' action

When using the URL filter 'Exempt' option, webfilter, antivirus and dlp scans are bypassed by default, so use this option only for trusted sites.

Configuration notes: You need to configure 'Exempt' actions in the URL filter if you want to bypass the FortiGuard Web Filter.You can configure which particular inspection(s) you want to bypass using the `set exempt` command in `config webfilter urlfilter`.

Deep Scan

The 'Deep Scan' feature is much heavier on resources than 'HTTPS URL Scan Only'. Deep Scan is much more accurate, since many sites (such as various Google applications) cannot be scanned separately without deep scanning enabled.

Note: If you configure Deep Scan in the SSL profile and then configure 'Enable HTTPS URL Scan Only' in the web filter profile, then Deep Scan is not performed.

Web filtering

FortiGuard Web Filtering can help stop infections from malware sites and help prevent communication if an infection occurs.

- Enable FortiGuard Web Filtering at the network edge.
- Install the FortiClient application and use FortiGuard Web Filtering on any systems that bypass your FortiGate unit.
- Block categories such as Pornography, Malware, Spyware, and Phishing. These categories are more likely to be dangerous

Patch management

When vulnerabilities are discovered in software, the software vendors release updates that fix these problems. Keeping your software and operating system up-to-date is a vital step to prevent infection and defend against attacks.

- Follow the latest advisories and reports on the FortiGuard webpage.
- Apply updates to all software as the updates become available.
- FortiGuard Vulnerability Management can help identify security weaknesses in your network. This subscription service is available through FortiScan and FortiAnalyzer units.
- Apply firmware updates to your FortiGate unit as they are released.
- Subscribe to FortiGuard AntiVirus and IPS services, so that AntiVirus and IPS scanning engines are automatically updated when new version are released.

Policy configuration

Configuring the FortiGate unit with an 'allow all' traffic policy is very undesirable. While this does greatly simplify the configuration, it is less secure. As a security measure, it is best practice for the policy rulebase to 'deny' by default, and not the other way around.

Policy configuration changes

On a heavy-loaded system, plan configuration changes during low usage periods in order to minimize impact on CPU usage and established sessions. In this scenario, it is considered a best practice to de-accelerate the hardware-accelerated sessions.

You can configure de-accelerated behaviour on hardware-accelerated sessions using CLI commands to control how the processor manages policy configuration changes. The following CLI commands are to be used:

```
config system settings
   set firewall-session-dirty { check-all | check-new | check-policy-option }
end
```

where you want the following to be true:

`check-all`	CPU flushes all current sessions and re-evaluates them. This is the default option.
`check-new`	CPU keeps existing sessions and applies policy changes to new sessions only. This reduces CPU load and the possibility of packet loss.
`check-policy-option`	Use the option selected in the `firewall-session-dirty` field of the firewall policy (`check-all` or `check-new`, as above, but per policy).

Policy whitelisting

- Allow only the necessary inbound and outbound traffic.
- If possible, limit traffic to specific addresses or subnets. This allows the FortiGate unit to drop traffic to and from unexpected addresses.

IPS and DoS policies

- Because it is critical to guard against attacks on services that you make available to the public, configure IPS signatures to block matching signatures. For example, if you have a web server, configure the action of web server signatures to Block.
- Your FortiGate unit includes IPS signatures written to protect specific software titles from DoS attacks. Enable the signatures for the software you have installed and set the signature action to Block.
- DoS attacks are launched against vulnerabilities. Maintain a FortiGuard IPS subscription to ensure your FortiGate unit automatically receives new and updated IPS signatures as they are released.
- Use and configure DoS policies to appropriate levels based on your network traffic and topology. This will help drop traffic if an abnormal amount is received. The key is to set a good threshold. The threshold defines the maximum number of sessions/packets per second of normal traffic. If the threshold is exceeded, the action is triggered. Threshold defaults are general recommendations, but your network may require very different values. One way to find the correct values for your environment is to set the action to Pass and enable logging. Observe the logs and adjust the threshold values until you can determine the value at which normal traffic begins to generate attack reports. Set the threshold above this value with the margin you want. Note that the smaller the margin, the more protected your system will be from DoS attacks, but your system will also be more likely to generate false alarms.

Networking

When configuring your network, ensure that there is no 'back door' access to the protected network. For example, if there is a wireless access point, it must be appropriately protected with password and encryption.

Be sure to also maintain an up-to-date network diagram which includes IP addressing, cabling, and network elements.

Routing configuration

- Always configure a default route.
- Add blackhole routes for subnets reachable using VPN tunnels. This ensures that if a VPN tunnel goes down, traffic is not mistakingly routed to the Internet unencrypted.

Policy routing

Keep the number of policy routes to a minimum to optimize performance in route lookup and to simplify troubleshooting.

Dynamic routing

- Select a Router ID that matches an IP assigned to an interface. This avoids the likelihood of having two devices with the same router ID.
- For routing over an IPsec tunnel, assign IP addresses to both ends of the tunnel.

Advanced routing

Use the following best practices for advanced routing when dealing with Border Gateway Protocol (BGP) and Open Shortest Path First (OSPF).

Border Gateway Protocol (BGP)

If you are using BGP, it is recommended that you enable soft-reconfiguration. This has two benefits:

- It allows you to perform 'soft clear' of peers after a change is made to a BGP policy.
- It provides greater visibility into the specific prefixes learned from each neighbor.

Leave soft-reconfiguration disabled if your FortiGate does not have much unused memory. Soft-reconfiguration requires keeping separate copies of prefixes received and advertised, in addition to the local BGP database.

Open Shortest Path First (OSPF)

- Avoid use of passive interfaces wherever possible.
- Avoid use of virtual links to connect areas. All areas should be designed to connect directly to the backbone area.
- Ensure that all backbone routers have a minimum of two peering connections to other backbone neighbors.
- An entire OSPF domain should be under common administration.

Network Address Translation (NAT)

- Beware of misconfiguring the IP Pool range. Double-check the start and end IPs of each IP pool. The IP pool should not overlap with addresses assigned to FortiGate interfaces or to any hosts on directly connected networks.
- If you have internal and external users accessing the same servers, use split DNS to offer an internal IP to internal users so that they don't have to use the external-facing VIP.

Configuring NAT

Do not enable NAT for inbound traffic unless it is required by an application. If, for example, NAT is enabled for inbound SMTP traffic, the SMTP server might act as an open relay.

Transparent Mode

- Do not connect two ports to the same VLAN on a switch or to the same hub. Some Layer 2 switches become unstable when they detect the same MAC address originating on more than one switch interface or from more than one VLAN.
- If you operate multiple VLANs on your FortiGate unit, assign each VLAN id to its own forwarding domain to ensure that the scope of the broadcast does not extend beyond the VLAN it originated in.

To protect against Layer 2 loops:

- Enable `stpforward` on all interfaces.
- Use separate VDOMs for production traffic (TP mode VDOM) and management traffic (NAT/Route mode VDOM).
- Only place those interfaces used for production in the TP mode VDOM. Place all other interfaces in the NAT/Route mode VDOM. This protects against potential Layer 2 loops.

Using Virtual IPs (VIPs)

- Use the external IP of 0.0.0.0 when creating a VIP for a FortiGate unit where the external interface IP address is dynamically assigned.
- Be sure to select the correct external interface when creating a new virtual IP (VIP). The external interface should be set to the interface at which the FortiGate unit receives connection requests from external networks.

FGCP High Availability

Fortinet suggests the following practices related to high availability:

- Use Active-Active HA to distribute TCP and UTM sessions among multiple cluster units. An active-active cluster may have higher throughput than a standalone FortiGate unit or than an active-passive cluster.
- Use a different host name on each FortiGate unit when configuring an HA cluster. Fewer steps are required to add host names to each cluster unit before configuring HA and forming a cluster.
- Consider adding an Alias to the interfaces used for the HA heartbeat so that you always get a reminder about what these interfaces are being used for.
- Enabling `load-balance-all` can increase device and network load since more traffic is load-balanced. This may be appropriate for use in a deployment using the firewall capabilities of the FortiGate unit and IPS but no other content inspection.
- An advantage of using session pickup is that non-content inspection sessions will be picked up by the new primary unit after a failover. The disadvantage is that the cluster generates more heartbeat traffic to support session pickup as a larger portion of the session table must be synchronized. Session pickup should be configured only when required and is not recommended for use with SOHO FortiGate models. Session pickup should only be used if the primary heartbeat link is dedicated (otherwise the additional HA heartbeat traffic could affect network performance).
- If session pickup is not selected, after a device or link failover all sessions are briefly interrupted and must be re-established at the application level after the cluster renegotiates. For example, after a failover, users browsing the web can just refresh their browsers to resume browsing. Users downloading large files may have to restart their download after a failover. Other protocols may experience data loss and some protocols may require sessions to be manually restarted. For example, a user downloading files with FTP may have to either restart downloads or restart their FTP client.
- If you need to enable session pickup, consider enabling `session-pickup-delay` to improve performance by reducing the number of sessions that are synchronized. See Session failover (session-pickup) on page 1884.
- Consider using the `session-sync-dev` option to move session synchronization traffic off the HA heartbeat link to one or more dedicated session synchronization interfaces. See Session failover (session-pickup) on page 1884.
- To avoid unpredictable results, when you connect a switch to multiple redundant or aggregate interfaces in an active-passive cluster you should configure separate redundant or aggregate interfaces on the switch; one for each cluster unit.
- Use SNMP, syslog, or email alerts to monitor a cluster for failover messages. Alert messages about cluster failovers may help find and diagnose network problems quickly and efficiently.

Heartbeat interfaces

Fortinet suggests the following practices related to heartbeat interfaces:

Do not use a FortiGate switch port for the HA heartbeat traffic. This configuration is not supported.

- Configure at least two heartbeat interfaces and set these interfaces to have different priorities.

- For clusters of two FortiGate units, as much as possible, heartbeat interfaces should be directly connected using patch cables (without involving other network equipment such as switches). If switches have to be used they should not be used for other network traffic that could flood the switches and cause heartbeat delays.
  - If you cannot use a dedicated switch, the use of a dedicated VLAN can help limit the broadcast domain to protect the heartbeat traffic and the bandwidth it creates.
- For clusters of three or four FortiGate units, use switches to connect heartbeat interfaces. The corresponding heartbeat interface of each FortiGate unit in the cluster must be connected to the same switch. For improved redundancy use a different switch for each heartbeat interface. In that way if the switch connecting one of the heartbeat interfaces fails or is unplugged, heartbeat traffic can continue on the other heartbeat interfaces and switch.
- Isolate heartbeat interfaces from user networks. Heartbeat packets contain sensitive cluster configuration information and can consume a considerable amount of network bandwidth. If the cluster consists of two FortiGate units, connect the heartbeat interfaces directly using a crossover cable or a regular Ethernet cable. For clusters with more than two units, connect heartbeat interfaces to a separate switch that is not connected to any network.
- If heartbeat traffic cannot be isolated from user networks, enable heartbeat message encryption and authentication to protect cluster information. See Enabling or disabling HA heartbeat encryption and authentication on page 1847.
- Configure and connect redundant heartbeat interfaces so that if one heartbeat interface fails or becomes disconnected, HA heartbeat traffic can continue to be transmitted using the backup heartbeat interface. If heartbeat communication fails, all cluster members will think they are the primary unit resulting in multiple devices on the network with the same IP addresses and MAC addresses (condition referred to as *Split Brain*) and communication will be disrupted until heartbeat communication can be reestablished.
- Do not monitor dedicated heartbeat interfaces; monitor those interfaces whose failure should trigger a device failover.
- Where possible at least one heartbeat interface should not be connected to an NP4 or NP6 processor to avoid NP4 or NP6-related problems from affecting heartbeat traffic.
- Where possible, the heartbeat interfaces should not be connected to an NP4 or NP6 processor that is also processing network traffic.
- Where possible, each heartbeat interface should be connected to a different NP4 or NP6 processor.
- Any FortiGate interface can be used as a heartbeat interface including 10/100/1000Base-T, SFP, QSFP fiber and copper, and so on. If you set up two or more interfaces as heartbeat interfaces each interface can be a different type and speed.

Interface monitoring (port monitoring)

Fortinet suggests the following practices related to interface monitoring (also called port monitoring):

- Wait until a cluster is up and running and all interfaces are connected before enabling interface monitoring. A monitored interface can easily become disconnected during initial setup and cause failovers to occur before the cluster is fully configured and tested.
- Monitor interfaces connected to networks that process high priority traffic so that the cluster maintains connections to these networks if a failure occurs.
- Avoid configuring interface monitoring for all interfaces.
- Supplement interface monitoring with remote link failover. Configure remote link failover to maintain packet flow if a link not directly connected to a cluster unit (for example, between a switch connected to a cluster interface and the network) fails. See Remote link failover on page 1873.

WAN Optimization

WAN Optimization features require significant memory resources and generate a high amount of I/O on disk. Before enabling WAN Optimization, ensure that the memory usage is not too high. If possible, avoid other disk-intensive features such as heavy traffic logging on the same disk as the one configured for WAN Optimization needs.

In general, it is preferable to enable the Transparent Mode checkbox and ensure that routing between the two endpoints is acceptable. Some protocols may not work well without enabling Transparent Mode.

Other best practices for utilizing the WAN Optimization feature follow.

Sharing the WAN Opt. tunnel for traffic of the same nature

WAN optimization tunnel sharing is recommended for similar types of WAN optimization traffic (such as CIFS traffic from different servers). However, tunnel sharing for different types of traffic is not recommended. For example, aggressive and non-aggressive protocols should not share the same tunnel.

Ordering WAN Opt. rules appropriately

- Precise, port specific WAN Optimization rules should be at the top of the list.
- Generic rules, such as overall TCP, should be at the bottom of the list.

Avoiding mixing protocols in a WAN Opt. tunnel

Different protocols may be more or less talkative or interactive . Mixing protocols in a tunnel may result in a delay for some of them. It is recommended to define protocol specific wan-optimization rules and restrict the ports to the necessary ones only for performance reasons.

Setting correct configuration options for CIFS WAN Opt.

Ensure that the WAN Optimization rules cover TCP ports 139 and 445 (on the same or two different rules). Also ensure that Transparent Mode is selected.

Setting correct configuration options for MAPI WAN Opt.

For MAPI WAN Optimization, only specify a rule with TCP port 135 (unless the MAPI control port is configured differently). Derived data sessions using other random ports will be handled by the CIFS wan-optimization daemon even with only the control port configured.

Testing WAN Opt. in a lab

- Ensure that WAN emulators are used to simulate the WAN. If no WAN emulator is used, it is expected to have better results without WAN Optimization than with WAN Optimization.
- To test the difference between cold transfers (first-time transfers) and warm transfers, it is recommended to generate a random file of the cold transfer to ensure that the test is the first time that the file has been seen.

Regarding byte compression and type of file

Enabling byte compression on file transfers already compressed (.jpeg files, compressed archive, etc.) won't provide any performance increase and could be seen as a misuse of CPU resources.

Regarding network address translation (NAT)

Selecting the NAT feature in a security policy does not have any influence on WAN Optimization traffic.

High Availability

There is no benefit to using active-active mode, so for pure WAN Optimization needs, use active-passive mode. Refer to the FGCP High Availability section for other best practices related to HA.

Authentication with specific peers

Configure WAN optimization authentication with specific peers. Accepting any peer is not recommended as this can be less secure.

Virtual Domains (VDOMs)

VDOMs can provide separate firewall policies and, in NAT/Route mode, completely separate configurations for routing and VPN services for each connected network or organization. This section provides a list of best practices for configuring VDOMs.

Per-VDOM resource settings

While Global resources apply to resources shared by the whole FortiGate unit, per-VDOM resources are specific to only one Virtual Domain.

By default all the per-VDOM resource settings are set to no limits. This means that any single VDOM can use up all the resources of the entire FortiGate unit if it needs to do so. This would starve the other VDOMs for resources to the point where they would be unable to function. For this reason, it is recommended that you set some maximums on resources that are most vital to your customers.

Virtual domains in NAT/Route mode

Once you have enabled virtual domains and created one or more VDOMs, you need to configure them. It is recommended that you perform the following tasks in the order given (while you may not require all for your network topology):

1. Change the management virtual domain.
2. Configure FortiGate interfaces in a NAT/Route VDOM.
3. Configure VDOM routing.
4. Configure security policies for NAT/Route VDOMs.
5. Configure UTM profiles for NAT/Route VDOMs.
6. Test the configuration.

Virtual clustering

If you decide to disable override for clurstering, as a result of persistent renegotiating, you should disable it for both cluster units.

Explicit proxy

- For explicit proxies, when configuring limits on the number of concurrent users, you need to allow for the number of users based on their authentication method. Otherwise you may run out of user resources prematurely.
- Each session-based authenticated user is counted as a single user using their authentication membership (RADIUS, LDAP, FSSO, local database etc.) to match users in other sessions. So one authenticated user in multiple sessions is still one user.
- For all other situations, the source IP address is used to determine a user. All sessions from a single source address are assumed to be from the same user.
- Set the explicit web proxy and explicit FTP proxy Default Firewall Policy Action to Deny. This means that a firewall policy is required to use these explicit proxies, allowing you to control access and impose security features.
- Do not enable the explicit web or FTP proxy on an interface connected to the Internet. This is a security risk because anyone on the Internet who finds the proxy could use it to hide their source address. If you must enable the proxy on such an interface make sure authentication is required to use the proxy.

Wireless

The following section contains a list of best practices for wireless network configurations with regard to encryption and authentication, geographic location, network planning, power usage, client load balancing, local bridging, SSIDs, and the use of static IPs.

Encryption and authentication

It is best practice to always enable the strongest user authentication and encryption method that your client supports. Fortinet recommends the following security, in order of strongest to weakest:

- WPA2 - Enterprise 802.1x/EAP - Personal pre-shared key (8-63 characters)
- WPA - Enterprise 802.1x/EAP - Personal pre-shared key (8-63 characters)
- WEP128 - 26 Hexadecimal digit key
- WEP64 - 10 Hexadecimal digit key
- None - Open system

Geographic location

Ensure that the FortiGate wireless controller is configured for your geographic location. This ensures that the available radio channels and radio power are in compliance with the regulations in your region.

The maximum allowed transmitter power and permitted radio channels for Wi-Fi networks depend on the region in which the network is located. By default, the WiFi controller is configured for the United States. If you are located in any other region, you need to set your location before you begin configuring wireless networks.

The location setting can only be changed from CLI. To change the country to France, for example, enter the following:

```
config wireless-controller setting
   set country FR
end
```

To see the list of country codes, enter a question mark ('?') in place of the country code.

Using an incorrect geographic location is a common error that can lead to unpredicable results on the client side.

Network planning

It is recommended that you perform a proper site survey prior positioning the wireless access point. In order to evaluate the coverage area environment, the following criteria must be taken into account:

- Size of coverage area
- Bandwidth required
- Client wireless capabilities

After completing a RF site survey, you'll have a good idea of the number and location of access points needed to provide users with adequate coverage and performance.

However, prior to installing the access points, be sure to determine the RF channel(s) you plan to use. This will ensure that users can roam throughout the facility with substantial performance.

To avoid co-channel interference, adjacent Wi-Fi APs must be configured to use non-overlapping channels. Otherwise, you'll find poor performance will degrade because of interference between access points.

It is recommended to statically configure the non-overlapping channels on every access point, using one Custom AP profile per AP (or group of APs). If static configuration cannot be used, the FortiOS Wi-Fi Controller includes the Automatic Radio Resource Provisioning (ARRP) feature.

Lowering the power level to reduce RF interference

Relevant Product(s): FortiAP

Reducing power reduces unwanted coverage and potential interference to other WLANs. Areas of unwanted coverage are a potential security risk. If possible, reduce the transmitter power of your wireless access point so that the signal is not available beyond the areas where it is needed. Auto Tx Power Control can be enabled to automatically adjust the transmit power.

In cases where customers complain about slow wireless traffic through a FortiAP, it might be necessary to try to reduce the possibility of RF interference. It is best practice not to locate FortiAPs near steel beams or other interfering materials. You can try using a wireless sniffer tool to collect the wireless packets and then analyze the extent of air interference.

A common mistake is spacing FortiAPs based upon the 5Ghz radio frequency. The 2.4Ghz signal travels further.

You have two options when confronted with slow wireless traffic through a FortiAP:

Option #1: Reducing transmit power

Perform a speed test and record the results. Set one of the radios on a FortiAP to be in dedicated monitoring mode. Then observe how many APs are detected. If the number of APs is too high (i.e., greater than 20), try reducing the transmit power in the WTP profile for the FortiAPs until the number of dedicated APs has dropped significantly.

Repeat the speed test.

Option #2: Ensuring that VAPs are distributed over the available channels

No built-in tools are available to measure RF interference directly. However, FortiOS 5.0 does allow for automatic power adjustment, which should minimize the occurrence of RF interference.

Wireless client load balancing

Wireless load balancing allows your wireless network to more efficiently distribute wireless traffic among wireless access points and available frequency bands. FortiGate wireless controllers support the following types of client load balancing:

- **Access Point Hand-off** - The wireless controller signals a client to switch to another access point.
- **Frequency Hand-off** - The wireless controller monitors the usage of 2.4GHz and 5GHz bands, and signals clients to switch to the lesser-used frequency.

Local bridging

Whenever possible, use local bridging to offload the CAPWAP tunnel. Note that in this case, Wi-Fi client devices obtain IP addresses from the same DHCP server as wired devices on the LAN. The vlan ID can only be configured

from the CLI:

```
config wireless-controller vap
   edit "vaplocalbridge"
      set vdom "root"
      set ssid "testvaplocalbridge"
      set local-bridging enable
      set vlanid 40 ---> only available in CLI
   next
end
```

Advertising SSIDs

- It is highly recommended to advertise the SSID. It makes it easier for customers and wireless clients. Also, if you 'hide' the SSID (known as 'network cloaking'), then clients will always look for it when they're outside the coverage area, which searches for known SSIDs, in effect leaking the SSID anyway. Refer to RFC 3370. Furthermore, many of the latest Broadcom drivers do not support hidden SSID for WPA2.
- For security reason, you might want to prevent direct communication between your wireless clients. In this case, enable Block Intra-SSID Traffic (in the SSID configuration).
- In a network with multiple wireless controllers, you need to change the mesh SSID so that each mesh root has a unique SSID. Other controllers using the same mesh root SSID might be detected as fake or rogue APs. Go to **WiFi & Switch Controller > SSID** to change the SSID. Fortinet also recommends that you create a new preshared key instead of using the default.

Using static IPs in a CAPWAP configuration

In a large FortiAP deployment with more than 20 FortiAPs connecting to a Fortigate Wireless Controller (AC), it is recommended to use static IPs on the access points instead of DHCP, setting the AC IP statically and the AC discovery type to static (Type 1), instead of learning it through broadcast, multicast, or DHCP.

This makes management of the APs easier since you know the exact IP of each access point. Troubleshooting also becomes easier as the debug of the AC controller won't continuously attempt the different discovery methods in sequence (broadcast > multicast > static).

Logging and reporting

The default log device settings must be modified so that system performance is not compromised. The FortiGate unit, by default, has all logging of FortiGate features enabled, except for traffic logging. The default logging location will be either the FortiGate unit's system memory or hard disk, depending on the model. Units with a flash disk are not recommended for disk logging.

Log management

When the FortiGate unit records FortiGate activity, valuable information is collected that provides insight into how to better protect network traffic against attacks, including misuse and abuse. There is a lot to consider before enabling logging on a FortiGate unit, such as what FortiGate activities to enable and which log device is best suited for your network's logging needs. A plan can help you in deciding the FortiGate activities to log, a log device, as well as a backup solution in the event the log device fails.

This plan should provide you with an outline, similar to the following:

- What FortiGate activities you want and/or need logged (for example, security features).
- The logging device best suited for your network structure.
- If you want or require archiving of log files.
- Ensuring logs are not lost in the event a failure occurs.

After the plan is implemented, you need to manage the logs and be prepared to expand on your log setup when the current logging requirements are outgrown. Good log management practices help you with these tasks.

Log management practices help you to improve and manage logging requirements. Logging is an ever-expanding tool that can seem to be a daunting task to manage. The following management practices will help you when issues arise, or your logging setup needs to be expanded.

- Revisit your plan on a yearly basis to verify that your logging needs are being met by your current log setup. For example, your company or organization may require archival logging, but not at the beginning of your network's lifespan. Archival logs are stored on a FortiGate unit's local hard drive, a FortiAnalyzer unit, or a FortiCloud server, in increasing order of size.
- Configure an alert message that will notify you of activities that are important to be aware about. For example: if a branch office does not have a FortiGate administrator, you will need to know at all times that the IPsec VPN tunnel is still up and running. An alert email notification message can be configured to send only if IPsec tunnel errors occur.
- If your organization or company uses peer-to-peer programs such as Skype or other instant messaging software, use the IM usage dashboard widget or the Executive Summary's report widget (Top 10 Application Bandwidth Usage Per Hour Summary) to help you monitor the usage of these types of instant messaging software. These widgets can help you in determining how these applications are being used, including if there is any misuse and abuse. Their information is taken from application log messages; however, application log messages should be viewed as well since they contain the most detailed information.
- Ensure that your backup solution is up-to-date. If you have recently expanded your log setup, you should also review your backup solution. The backup solution provides a way to ensure that all logs are not lost in the event that the log device fails or issues arise with the log device itself.

- When downloading log messages and viewing them on a computer, the log file will be downloaded like any other file. Log file names contain their log type and date in the name, so it is recommended to create a folder in which to archive your log messages, as they can be sorted easily.

System memory and hard disks

If the FortiGate unit has a hard disk, it is enabled by default to store logs. This also means that you do not have to enable this and configure the settings for logging to the hard disk, but modify these settings so that it is configured for your network logging requirements.

If the FortiGate unit has only flash memory, disk logging is disabled by default, as it is not recommended. Constant rewrites to flash drives can reduce the lifetime and efficiency of the memory. It must be enabled in the CLI under config log disk setting.

For some low-end models, disk logging is unavailable. Check a product's Feature Matrix for more information. In either case, Fortinet recommends using either a FortiAnalyzer unit or the FortiCloud service.

Chapter 6 - FortiGate-6000

Fortigate-6000

FortiGate-6000 overview

The FortiGate-6000 series is a collection of 3U 19-inch rackmount appliances that all include twenty-four 25GigE SFP28 and four 100GigE QSFP28 data network interfaces, as well as NP6 and CP9 processors to deliver high IPS/threat prevention performance.

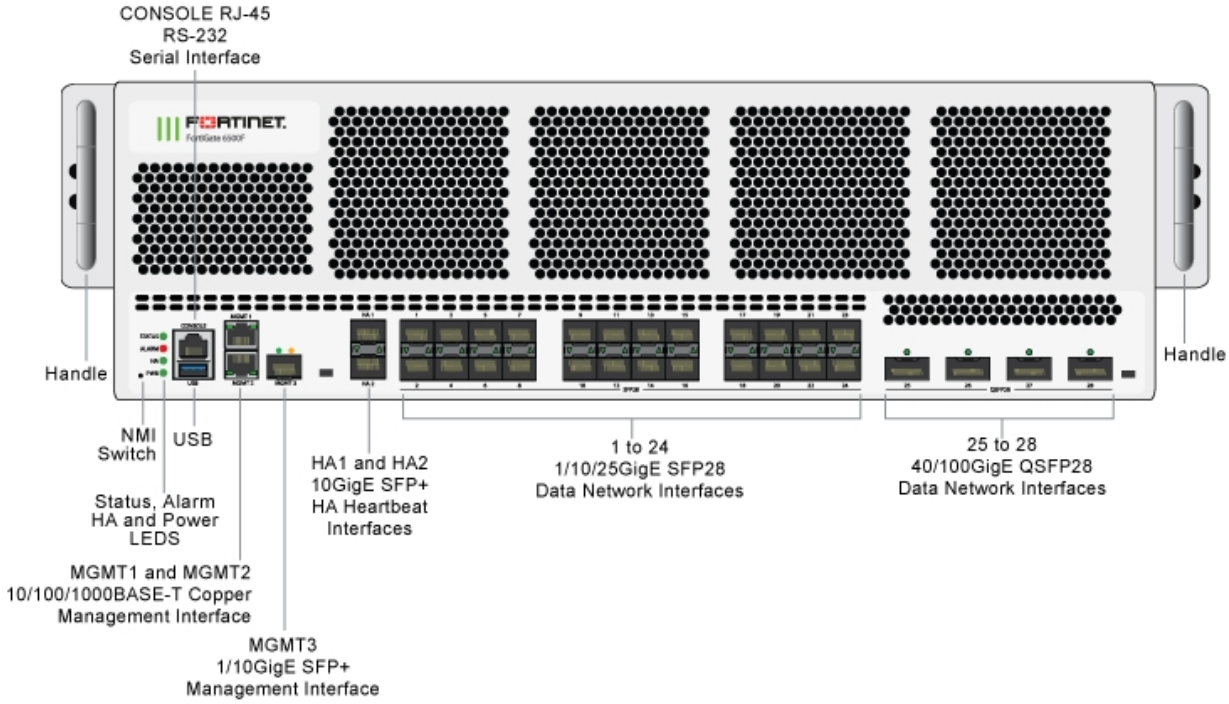
Currently, four FortiGate-6000 models are available:

- FortiGate-6500F
- FortiGate-6501F
- FortiGate-6300F
- FortiGate-6301F

All FortiGate-6000 models have the same front and back panel configuration including the same network interfaces. The differences are the processing capacity of the individual models. All FortiGate-6000 models include internal Fortinet Processor Cards (FPCs) that contain NP6 and CP9 security processors. The FortiGate-6000 uses session-aware load balancing to distribute sessions to the FPCs. The FortiGate-6500F includes ten FPCs and the FortiGate-6300F includes six FPCs.

Also the FortiGate-6501F and 6301F models are the same as their related models with the addition of two internal 1 TByte log disks.

FortiGate-6000 front panel (FortiGate-6500F shown)



Front panel interfaces

All FortiGate-6000 models have the following front panel interfaces:

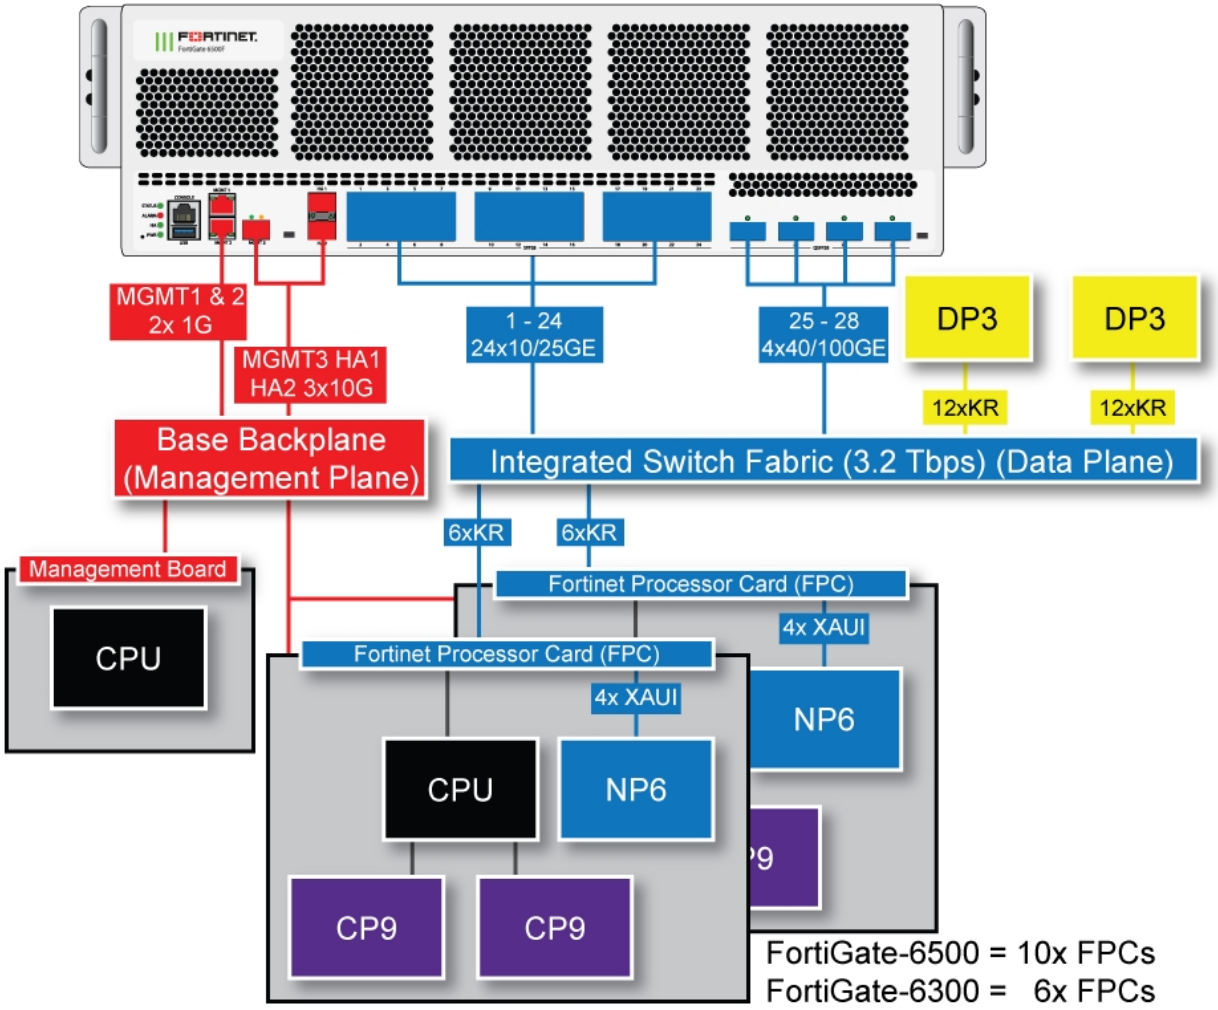
- Twenty-four 1/10/25GigE SFP28 data network interfaces (1 to 24). The default speed of these interfaces is 10Gbps.
- Four 40/100GigE QSFP28 data network interfaces (25 to 28). The default speed of these interfaces is 40Gbps.
- Two front panel 1/10GigE SFP+ HA interfaces (HA1 and HA2) used for heartbeat, session sync, and management communication between two and only two FortiGate-6000s in an HA cluster. The default speed of these interfaces is 10Gbps. Operating them at 1Gbps is not recommended. A FortiGate-6000 cluster consists of two (and only two) FortiGate-6000s of the same model. To set up HA, you can use a direct cable connection between the FortiGate-6000s HA1 interfaces and a second direct cable connection between the HA2 interfaces. For more information about FortiGate-6000 HA, see FortiGate-6000 high availability (FGCP) on page 781.
- Two 10/100/1000BASE-T out of band management Ethernet interfaces (MGMT1 and MGMT2).
- One front panel 1/10GigE SFP+ out of band management interface (MGMT3). You can use the 10Gbps MGMT3 interface for additional bandwidth management traffic that might be useful for high bandwidth activities such as remote logging.
- One RJ-45 RS-232 serial console connection.
- One USB connector.

FortiGate-6000 schematic

The FortiGate-6000 has separate data and management planes. The data plane handles all traffic and security processing functionality. The management plane handles management functions such as administrator logins, configuration and session synchronization, SNMP and other monitoring, HA heartbeat communication, and

remote and (if supported) local disk logging. Separating these two planes means that resources used for traffic and security processing are not compromised by management activities.

FortiGate-6000 schematic



In the data plane, two DP3 load balancers use session-aware load balancing to distribute sessions from the front panel interfaces (port1 to 28) to Fortinet Processor Cards (FPCs). The DP3 processors communicate with the FPCs across the 3.2Tbps integrated switch fabric. Each FPC processes sessions load balanced to it. The FPCs send outgoing sessions back to the integrated switch fabric and then out the network interfaces to their destinations.

The NP6 processor in each FPC enhances network performance with fastpath acceleration that offloads communication sessions from the FPC CPU. The NP6 processor can also handle some CPU intensive tasks, like IPsec VPN encryption/decryption.

The CP9 processors in each FPC accelerate many common resource intensive security related processes such as SSL VPN, Antivirus, Application Control, and IPS.

The management plane includes the management board, base backplane, management interfaces, and HA heartbeat interfaces. Configuration and session synchronization between FPCs in a FortiGate-6000F occurs over the base backplane. In an HA configuration, configuration and session synchronization between the FortiGate-6000s in the cluster takes place over the HA1 and HA2 interfaces. Administrator logins, SNMP monitoring, remote logging to one or more FortiAnalyzers or syslog servers, and other management functions use the MGMT1, MGMT2, and MGMT3 interfaces. You can use the 10Gbps MGMT3 interface for additional bandwidth that might be useful for high bandwidth activities such as remote logging.

Getting started with FortiGate-6000

Once you have installed your FortiGate-6000 in a rack and connected it to power you should review the front and back panel LEDs to verify that everything is operating normally. Wait until the FortiGate-6000 has completely started up and synchronized before making configuration changes. You can use the `diagnose system ha status` command to confirm that the FortiGate-6000 is completely initialized. If the output from entering this command hasn't changed after checking for a few minutes you can assume that the system has initialized. You don't normally have to confirm that the system has initialized, but this diagnose command is available if needed.

You can connect to the MGMT1 Ethernet interface to log into the GUI or CLI. Connect to the GUI by browsing to https://192.168.1.99. Connect to the CLI by using SSH to connect to 192.168.1.99. Log into the GUI or CLI using the admin account with no password. You may have to enable SSH administrative access for the mgmt1 interface before you can connect to the CLI.

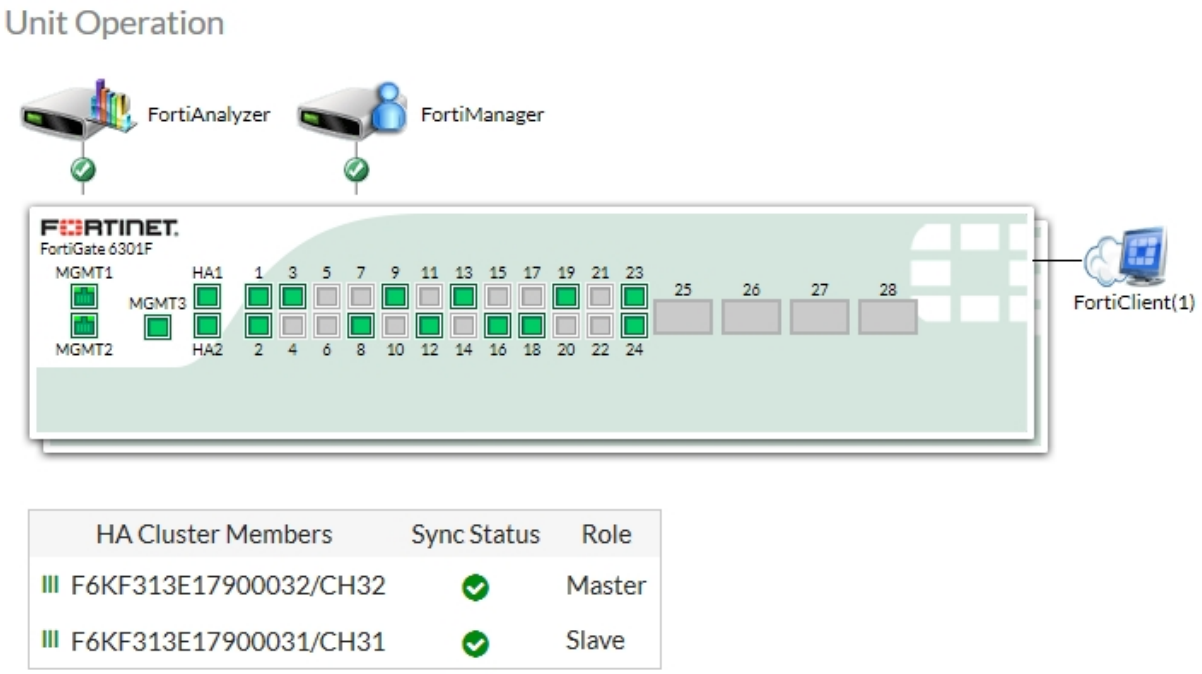
You can also connect to the CLI using the front panel Console port using the console cable shipped with your product. For the console connection, use the following settings: Baud Rate (bps) 9600, Data bits 8, Parity None, Stop bits 1, and Flow Control None.

For security reasons you should add a password to the admin account before connecting the FortiGate-6000 to your network.

Once you have logged into the GUI or CLI you can view and change the configuration of your FortiGate-6000 just like any FortiGate. For example, you can configure firewall policies between any two interfaces. You can also configure aggregates of the front panel interfaces.

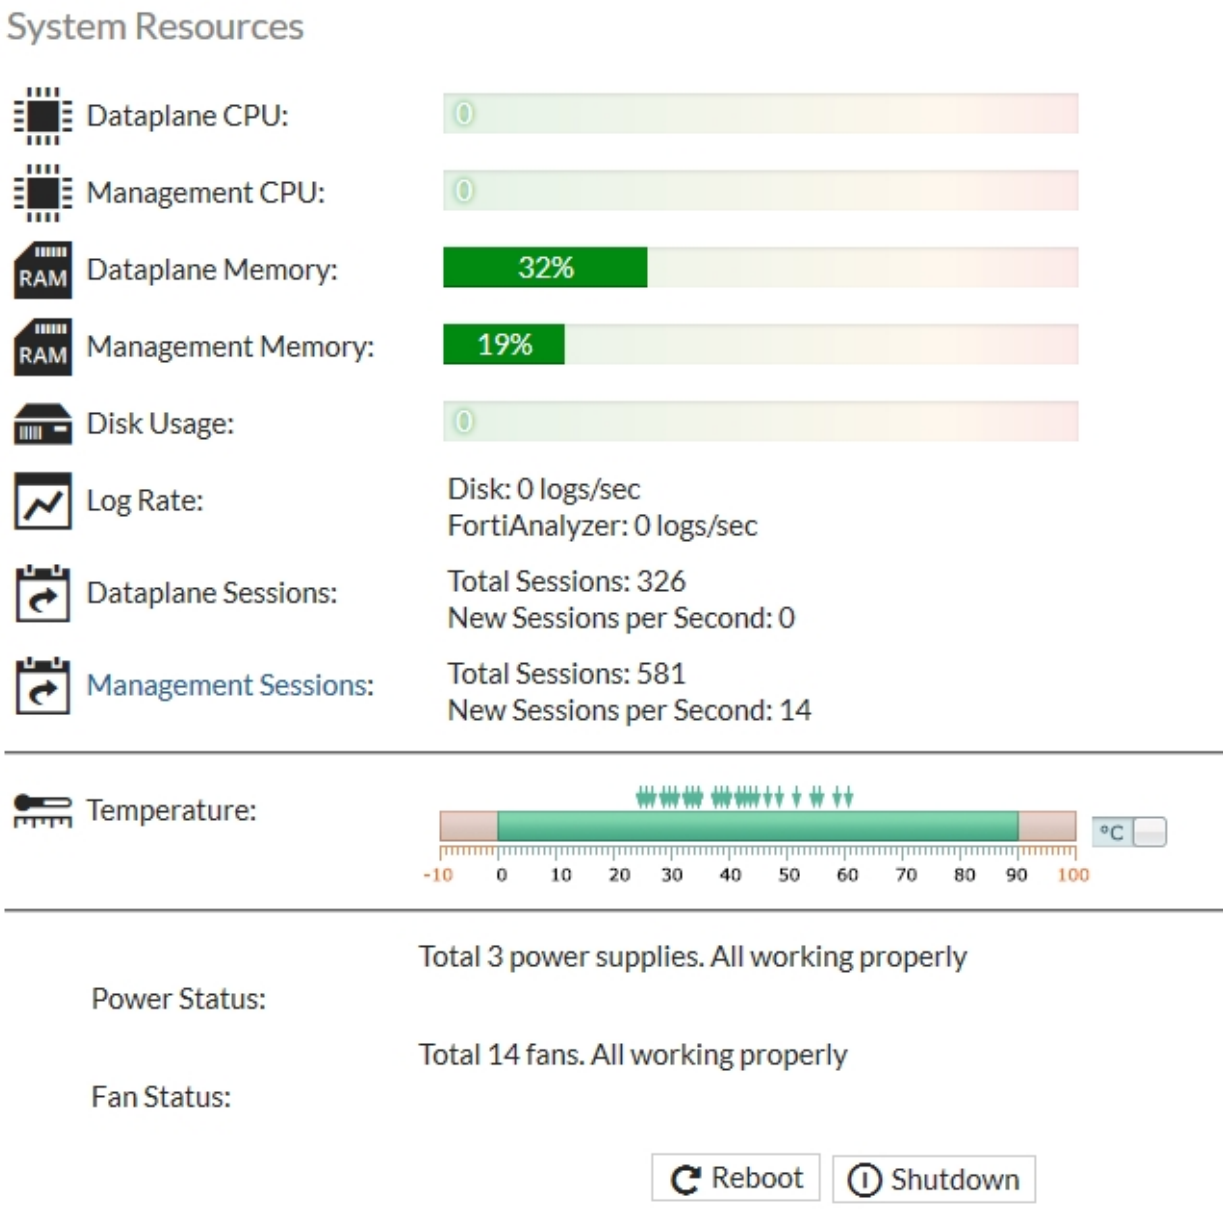
If you logged into the GUI you can use the dashboard to view the status of your FortiGate-6000 product. The following shows and example **Unit Operation** widget view for a FortiGate Clustering Protocol (FGCP) cluster of two FortiGate-6301Fs.

Example FortiGate-6301F cluster unit operation widget



The dashboard **System Resources** widget shows FortiGate-6000 specific information including the data plane and management plane CPU and memory usage and session count. You can also see the temperatures measured by the temperature sensors built into the FortiGate-6000 as well as the status of the three power supplies and fourteen fans.

Example FortiGate-6301F System Resources widget



Interface groups and changing data interface speeds

Depending on the networks that you want to connect your FortiGate-6000 to, you may have to manually change the data interface speeds. The port1 to port24 data interfaces are divided into the following groups:

- port1 - port4
- port5 - port8
- port9 - port12
- port13 - port16

- port17 - port20
- port21 - port24

All of the interfaces in a group operate at the same speed. Changing the speed of an interface changes the speeds of all of the interfaces in the same group. For example, if you change the speed of port18 from 10Gbps to 25Gbps the speeds of port17 to port20 are also changed to 25Gbps.

Another example, the default speed of the port1 to port24 interfaces is 10Gbps. If you want to install 25GigE transceivers in port1 to port24 to convert these data interfaces to connect to 25Gbps networks, you must enter the following from the CLI:

```
config system interface
   edit port1
      set speed 25000full
   next
   edit port5
      set speed 25000full
   next
   edit port9
      set speed 25000full
   next
   edit port13
      set speed 25000full
   next
   edit port17
      set speed 25000full
   next
   edit port21
      set speed 25000full
   end
```

Every time you change a data interface speed, when you enter the `end` command, the CLI confirms the range of interfaces affected by the change. For example, if you change the speed of port5 the following message appears:

```
config system interface
   edit port5
end
port5-port8 speed will be changed to 25000full due to hardware limit.
Do you want to continue? (y/n)
```

Configuring the management interfaces

The default FortiGate-6000 configuration includes a management VDOM named mgmt-vdom. The management interfaces mgmt1, mgmt2, and mgmt3 are all in this VDOM. The ha1 and ha2 interfaces are also in this VDOM. This mgmt-vdom cannot be removed or renamed and interfaces cannot be removed from it or added to it. Fortinet recommends managing the FortiGate-6000 from the mgmt1, mgmt2, and mgmt3 out-of-band management interfaces and not from a data interface.

You can change the IP address of the management interfaces and configure routing for the management VDOM as required. For example, from the GUI, select the **mgmt-vdom** then go to **Network > Interfaces** to configure the mgmt1, mgmt2, or mgmt3 interfaces.

From the CLI:

```
config system interface
   edit mgmt1
      set ip <ip-address> <netmask>
      etc
```

Using data interfaces for management traffic

Normally, all management traffic connects with the FortiGate-6000 through the MGMT1, MGMT2, and MGMT3 interfaces. The FortiGate-6000 does also support management traffic connections to the FortiGate-6000 data interfaces (port1 to port28). To enable management connections to these interfaces you must configure the VDOM that the data interfaces are included in to allow traffic forwarding to the management board. By default, the root VDOM includes all of the data interfaces. To allow management communication between the root VDOM and the management board, edit the root VDOM from the CLI and use the following command:

```
config vdom
   edit root
      config system settings
         set motherboard-traffic-forwarding {icmp | admin | auth}
   end
```

The `icmp` option, enabled by default, allows you to log into the management board from one of the MGMT interfaces and use the `execute ping` command to ping an address through one of the data interfaces. The interface used depends on the routing configuration.

The `admin` option allows Telnet, SSH, HTTP, and HTTPS administrator connections from a management PC to a data interface. You cannot configure data interfaces to accept management connections using non-standard ports.

The `auth` option allows authentication communication from external LDAP, RADIUS, or FSSO servers through data interfaces to the management board.

Currently, the `admin` and `auth` settings are in development and not recommended.

Viewing interface statistics

You can add Interface History dashboard widgets to view traffic in and traffic out and total traffic information about the traffic passing through any FortiGate-6000 interface. You can add an Interface Bandwidth widget to the dashboard for:

- Any physical interface
- Any link aggregation (LAG) interface
- Any member of a LAG
- Any VLAN interface
- Any IPsec VPN tunnel interface
- Any redundant interface

The displayed data includes all of the traffic processed by the interface, independent of how the traffic is load balanced.

You can add individual Interface History widgets for each interface that you want to monitor. When adding the widget you can select the interface to monitor and select different time periods for which to display data. The data displayed on the widget updates in real time if you select enable refresh. You can also scan your cursor over the graph on the widget to see traffic in and out of the interface, and the total traffic for different times on the graph.

From the CLI, for physical interfaces, you can use the `diagnose hardware deviceinfo nic <interface-name>` command to view transmitted and received packets.

For LAG and VLAN interfaces you can display transmitted and received packets using the `diagnose netlink interface list <interface-name>` command.

Changing the FortiGate-6301F and 6501F log disk configuration

The FortiGate-6301F and FortiGate-6501F both include two internal 1-TByte log disks in a RAID-1 configuration. In the RAID-1 configuration you can use the disks for disk logging only. You can use the `execute disk raid` command to disable RAID and use one of the disks for disk logging and the other for other purposes such as disk caching. You can also change the RAID level to RAID-0. Changing the RAID configuration deletes all data from the disks and can disrupt disk logging so a best practice is set the RAID configuration when initially setting up the FortiGate-6301F or 6501F.

You can see the RAID configuration from the **RAID Monitor** dashboard widget.

Select **Configure** to change the RAID level. You can select RAID-0 or RAID-1.

From the CLI you can use the following command to show disk status. The following command output shows the default disk status.

```
execute disk list

Disk RAID ref: 255 916.9GB, 915.9GB free type: RAID [RAID level 1] dev: /dev/md0
  Disk NVME-2 ref: 931.5GB type: SSD [NVME] dev: /dev/nvme0n1
  Disk NVME-3 ref: 931.5GB type: SSD [NVME] dev: /dev/nvme1n1
```

Use the following command to disable RAID:

```
execute disk raid disable
```

RAID is disabled, the disks are separated and formatted.

Use the following command to change the RAID level to RAID-0:

```
execute disk raid rebuild-level 0
```

The disks are formatted for RAID-0.

Use the following command to rebuild the current RAID partition:

```
execute disk raid rebuild
```

The RAID is rebuilt at the current RAID level.

Use the following command to show RAID status. The following command output shows the default RAID status.

```
execute disk raid status
RAID Level: Raid-1
RAID Status: OK
RAID Size: 1000GB

Disk 1: OK Used 953GB
Disk 2: OK Used 953GB
```

Managing individual FPCs

When you log into the GUI or CLI using the MGMT1 interface IP address you are actually connecting to the FortiGate-6000F management board (called slot 0 or MBD on the CLI). This is normally how you would connect to a FortiGate-6000F for administration.

In some cases you may want to connect to the individual Fortinet Processor Cards (FPCs) in your FortiGate-6000F. For example, you may want to view the traffic being processed by a specific FPC. You can connect to the GUI or CLI of individual FPCs in the chassis using the system management IP address with a special port number.

For example, if the system management IP address is 192.168.1.99 you can connect to the GUI of the first FPC using the system management IP address followed by the special port number, for example https://192.168.1.99:44301.

The special port number (in this case 44301) is a combination of the service port (for HTTPS the service port is 443) and the FPC slot number (in this example, 01). The following table lists the special ports to use to connect to each FPC slot using common admin protocols. The FortiGate-6300F and 6301F have 7 slots (0 to 6) and the FortiGate-6500 and 6501 have 11 slots (0 to 10).

FortiGate-6000 special administration port numbers

Slot Address	HTTP (80)	HTTPS (443)	Telnet (23)	SSH (22)	SNMP (161)
Chassis 1, Slot 0, (MBD)	8000	44300	2300	2200	16100
Chassis 1, Slot 1 (FPC01)	8001	44301	2301	2201	16101
Chassis 1, Slot 2 (FPC02)	8002	44302	2302	2202	16102
Chassis 1, Slot 3 (FPC03)	8003	44303	2303	2203	16103
Chassis 1, Slot 4 (FPC04)	8004	44304	2304	2204	16104
Chassis 1, Slot 5 (FPC05)	8005	44305	2305	2205	16105
Chassis 1, Slot 6 (FPC06)	8006	44306	2306	2206	16106
Chassis 1, Slot 7 (FPC07)	8007	44307	2307	2207	16107
Chassis 1, Slot 8 (FPC08)	8008	44308	2308	2208	16108
Chassis 1, Slot 9 (FPC09)	8009	44309	2309	2209	16109
Chassis 1, Slot 10 (FPC10)	8010	44310	23010	22010	16110

For example:

- To connect to the GUI of the FPC slot 3 using HTTPS you would browse to https://192.168.1.99:44303.
- To send an SNMP query to the FPC in slot 6 use port number 16106.

The configuration is the same no matter whether you log into the management board or an FPC. Logging into different FPCs allows you to use the FortiView or Monitor GUI pages to view the activity on that FPC. Even though you can log into different FPCs, you should only make configuration changes from the management board (slot 0 or MBD).

Connecting to individual FPC consoles

From the management board CLI, the `execute system console server` command provides access to individual FPC consoles in your FortiGate-6000. Console access can be useful for troubleshooting. For example, if an FPC does not boot properly you can use console access to view the state of the FPC and enter commands to fix the problem or restart the FPC.

For example, from the management board CLI, use the following command to log into the console of the FPC in slot 3:

```
execute system console-server connect 3
```

Authenticate to log into the console and use CLI commands to view information, make changes, or restart the FPC. When you are done, use **Ctrl-X** to exit from the console back to the management board CLI.

Also from the management board CLI you can use the `execute system console-server showline` command to list any active console server sessions. Only one console session can be active for each FPC, so before connecting to an FPC console, you can use this command to verify whether or not there is an active console session.

The following command output shows an active console session with the FPC in slot 4:

```
execute system console-server showline
MB console line connected - 1
Telnet-to-console line connected - 4
```

You can use the `execute system console-server clearline` command to clear an active console session. For example, the clear an active console session with the FPC in slot 4, enter:

```
execute system console-server clearline 4
```

The `execute system console-server` commands only allow access to FPCs in the FortiGate-6000 that you are logged into. You can't use this command to access FPCs in the other FortiGate-6000 in an HA configuration.

Connecting to individual FPC CLIs

From the management board CLI you can use the following command to switch between FPCs and perform different operations on the FPC in each slot:

```
execute load-balance slot {manage | nmi-reset | power-off | power-on | reboot} <chassis-
    number>.<slot-number>
```

Use `manage` to connect to the CLI of a different FPC, use the other options to perform an action on an individual FPC.

For example, to connect to the NPC in chassis 1 slot 4 enter:

```
execute load-balance slot manage 1.4
```

For example, to rebook the NPC in chassis 1 slot 3 enter:

```
execute load-balance slot reboot 1.3
```

Connecting to FPC CLIs using the console port

You can use the front panel console port to connect to the CLI of the management board and individual FPCs.

By default when the FortiGate-6000 first starts up the console port is connected to the management board. The default settings for connecting to the console port are:

Baud Rate (bps) 9600, Data bits 8, Parity None, Stop bits 1, and Flow Control None.

If you connect a PC to the console port with a serial cable and open a terminal session you can press Ctrl-T to enable console switching mode. Press Ctrl-T multiple times to cycle through the management board (MBD) and FPC CLIs (the new destination is displayed in the terminal window).

Once the console port connects to the CLI that you want to use, press Enter to enable the CLI and login.

When your session is complete you can press Ctrl-T to connect to another CLI.

Connecting the CLI of an individual FPC

Use the following steps to connect to the CLI of the FPC in slot 4: (FPC04)

1. Connect the console cable supplied with your FortiGate-6000 to the console port and to your PC or other device RS-232 console port.
2. Start a terminal emulation program on the PC. Use these settings:
   Baud Rate (bps) 9600, Data bits 8, Parity None, Stop bits 1, and Flow Control None.
3. Press Ctrl-T to enter console switch mode.
4. Repeat pressing Ctrl-T until you have connected to FPC04. Example prompt:
   ```
   <Switching to Console: FPC04 (9600)>
   ```
5. Login with an administrator name and password.
   The default is admin with no password. For security reasons, it is strongly recommended that you change the password.
6. When your session is complete, enter the `exit` command to log out.

Default VDOM and management VDOM configuration

By default when the FortiGate-6000 first starts up it is operating in multiple VDOM mode. The system has a management VDOM (named mgmt-vdom) and the root VDOM. The ha1, ha2, mgmt1, mgmt2, and mgmt3 interfaces are in mgmt-vdom and all of the data interfaces (port1 to port28) are in the root VDOM.

For the FortiGate-6000 system to operate normally you should not change the configuration of the mgmt-vdom VDOM and this VDOM should always be the management VDOM. You should also not add or remove interfaces from this VDOM. You can change the IP addresses of the mgmt1, mgmt2, and mgmt3 interfaces and you can add routes to the mgmt-vdom VDOM.

You have full control over the configurations of other FortiGate-6000 VDOMs.

Firmware upgrades

The management board and all of the FPCs in your FortiGate-6000 run the same firmware image. You upgrade the firmware from the management board GUI or CLI just as you would any FortiGate product. During the upgrade process, the firmware on the management board and all of the FPCs upgrade in one step. Firmware upgrades should be done during a quiet time because traffic will be interrupted for a short time during the upgrade process.

If you are operating two FortiGate-6000s in HA mode with `uninterruptable-upgrade` and `session-pickup` enabled, firmware upgrades should only cause a minimal traffic interruption. Use the following command to enable these settings. These settings are synchronized to all FPCs.

```
config system ha
   set uninterruptable-upgrade enable
   set session-pickup enable
end
```

Restarting the FortiGate-6000

To restart the FortiGate-6000, connect to the management board CLI and enter the command `execute reboot`. When you enter this command the management board and all of the FPCs reboot.

You can restart individual FPCs by logging into that FPC's CLI and entering the `execute reboot` command.

NMI switch and NMI reset commands

When working with Fortinet Support to troubleshoot problems with your FortiGate-6000 you can use the front panel non-maskable interrupt (NMI) switch to assist with troubleshooting. Pressing this switch causes the software to dump management board registers and backtraces to the console. After the data is dumped, the management board reboots. While the management board restarts, traffic is temporarily blocked. The management board should restart normally and traffic can resume once the management board is up and running.

You can use the following command to dump registers and backtraces of one or more FPCs to the console. After the data is dumped, the FPCs reboot. While the FPCs are rebooting, traffic is distributed to the remaining FPCs. The FPCs should restart normally and traffic can resume once they are up and running.

```
execute load-balance slot nmi-reset <slot-number(s)>
```

Where `<slot-number(s)>` can be one or more FPC slot numbers or slot number ranges with no space and separated by commas. For example:

```
execute load-balance slot nmi-reset 1,3-4
```

Configuration synchronization

When you make configuration changes from the management board, FortiGate-6000 synchronizes these configuration changes to the FPCs. To support configuration synchronization, the management board becomes the config-sync master and makes sure the configurations of all FPCs are synchronized. Every time you make a configuration change you must be logged in using the management address, which logs you into the management board.

You can use the `diagnose sys confsync status | grep in_sy` command to view the synchronization status of the management board and FPCs. The following example just shows a few output lines:

```
diagnose sys confsync status | grep in_sy
FPC6KF3E17900200, Slave, uptime=5385.45, priority=119, slot_id=2:1, idx=2, flag=0x4, in_sync=1
F6KF313E17900031, Slave, uptime=5484.74, priority=2, slot_id=1:0, idx=0, flag=0x10, in_sync=1
F6KF313E17900032, Master, uptime=5488.57, priority=1, slot_id=2:0, idx=1, flag=0x10, in_sync=1
FPC6KF3E17900201, Slave, uptime=5388.78, priority=120, slot_id=2:2, idx=2, flag=0x4, in_sync=1
F6KF313E17900031, Slave, uptime=5484.74, priority=2, slot_id=1:0, idx=0, flag=0x10, in_sync=1

...
```

The `in_sync=1` field indicates that the FPC is synchronized.

Failover in a standalone FortiGate-6000

A FortiGate-6000 will continue to operate even if one of the FPCs fails. If an FPC fails, sessions being processed by that FPC fail. All sessions are then load balanced to the remaining FPCs. Sessions that were being processed by the failed FPC are restarted and load balanced to the remaining FPCs.

An FPC can fail due to a hardware malfunction, a software problem, or a power supply failure. The FortiGate-6000 includes three hot-swappable power supplies in a 2+1 redundant configuration. At least two of the power supplies must be operating to provide power to the FortiGate-6000. If only one power supply is operating then some of the FPCs will be shut down. The FortiGate-6000 will continue to operate but with reduced performance because fewer FPCs are operating.

If FPCs fail due to a hardware failure, they are not customer replaceable. Instead you should RMA the FortiGate-6000.

You can use the `diagnose load-balance status` command to show the status of the FPCs. In the command output, if `Status Message` is `Running` the FPC is operating normally. For example, for a FortiGate-6301F:

```
diagnose load-balance status
================================================================================
MBD SN: F6KF313E17900032
  Master FPC Blade: slot-2

      Slot  1: FPC6KF3E17900200
        Status:Working   Function:Active
        Link:      Base: Up          Fabric: Up
        Heartbeat: Management: Good   Data: Good
        Status Message:"Running"
      Slot  2: FPC6KF3E17900201

        Heartbeat: Management: Good   Data: Good
        Status Message:"Running"
      Slot  6: FPC6KF3E17900169
        Status:Working   Function:Active
        Link:      Base: Up          Fabric: Up
        Heartbeat: Management: Good   Data: Good
```

```
Status Message:"Running"
```

Installing firmware on an individual FPC

You might want to install firmware in an individual FPC to resolve a problem with the FPC that may have caused it to stop processing traffic or otherwise stop working properly because of a software problem.

You can upload a firmware image from a TFTP server, an FTP server, or a USB key to an internal FortiGate-6000 TFTP server then install the firmware image from the internal TFTP server onto the FPC.

You use one of the following commands to upload a firmware image to the FortiGate-6000 TFTP server:

```
execute upload image ftp <image-file-and-path> <comment> <ftp-server-address> <username>
    <password>
execute upload image tftp <image-file> <comment> <tftp-server-address>
execute upload image usb <image-file-and path> <comment>
```

Then use the following command to install the firmware image on an FPC:

```
execute load-balance update image <slot-number>
```

Where `<slot-number>` is the FPC slot number.

This command uploads the firmware image to the FPC which then reboots. When the FPC starts up the it's configuration is reset to factory defaults and then synchronized by the management board. The FPC reboots again, rejoins the cluster, and can start processing traffic.

You can use the following command to verify that the configuration of the FPC has been synchronized. The command output below shows the sync status of some of the FPCs in an HA cluster of two FortiGate-6301Fs. The field `in_sync=1` indicates that the configuration of the FPC is synchronized.

```
diagnose sys confsync status | grep in_sy
FPC6KF3E17900207, Slave, uptime=72643.57, priority=18, slot_id=2:3, idx=2, flag=0x4, in_
    sync=1
F6KF313E17900031, Slave, uptime=72777.97, priority=2, slot_id=1:0, idx=0, flag=0x10, in_
    sync=1
F6KF313E17900032, Master, uptime=72783.53, priority=1, slot_id=2:0, idx=1, flag=0x10, in_
    sync=1
```

If `in_sync` is not equal to 1 or if an FPC is missing in the command output you can try restarting the FPC by entering `execute reboot` from the FPC`s CLI.

Packet sniffing for FPC and management board packets

From the management board CLI, you can use the `diagnose sniffer packet` command to view or sniff packets processed by the FPCs. To use this command log into the management board and edit a VDOM. This command includes a `<slot>` option to allow you to view packets processed by individual FPCs.

You can the `diagnose sniffer packet` command from an individual FPC CLO to view packets processed by that FPC.

From the management board the command syntax is:

```
diagnose sniffer packet <interface> <protocol-filter> <verbose> <count> <timestamp> <slot>
```

Where:

<interface> the name of one or more interfaces on which to sniff for packets. Use any to sniff packets for all interfaces.

<protocol-filter> a filter to select the protocol for which to view traffic. This can be simple, such as entering udp to view UDP traffic or complex to specify a protocol, port, and source and destination interface and so on.

<verbose> the amount of detail in the output, and can be:

1 display packet headers only.

2 display packet headers and IP data.

3 display packet headers and Ethernet data (if available).

4 display packet headers and interface names.

5 display packet headers, IP data, and interface names.

6 display packet headers, Ethernet data (if available), and interface names.

<count> the number of packets to view. You can enter Ctrl-C to stop the sniffer before the count is reached.

<timestamp> the timestamp format, a for UTC time and l for local time.

<slot> the FPC(s) for which to view packets.

- To view packets for one FPC enter the FPC's slot number.
- To view packets for more than one FPC, enter the slot numbers separated by commas. You can also include a range. For example, to view packets for the FPCs in slots 1, 2, 3, and 6 you can enter 1,2,3,6 or 1-3,6.
- To view packets for all FPCs, enter all.
- If you leave out the <slot> option, you can use the diagnose sniffer options slot command to set whether management board packets appear or whether management board and FPC packets appear.

Using the diagnose sniffer options slot command

You can use the diagnose sniffer options slot command to control what the diagnose sniffer packet command displays if you don't include the <slot> option. The default diagnose sniffer options slot setting causes the diagnose sniffer packet command to display packets processed by all FPCs and by the management board.

You can use the following command to only display packets processed by the management board:

```
diagnose sniffer options slot current
```

Then the next time you enter the diagnose sniffer packet command and leave out the <slot> option, only packets from the management board appear in the command output.

Filtering out internal management traffic

The FortiGate-6000 includes internal interfaces that process internal management and synchronization communication between FortiGate-6000 components. Because this traffic uses internal interfaces, if you specify one or more interface names in the diagnose sniffer packet command this traffic is filtered out. However, if you sniff traffic on any interface, internal management traffic can appear in the diagnose sniffer packet command output.

The `diagnose sniffer options filter-out-internal-pkts option` if enabled (the default), filters out this internal management traffic. You can disable this option if you want to see the internal management traffic in the `diagnose sniffer packet` output.

Load balancing and flow rules

This chapter provides an overview of how FortiGate-6000 Session-Aware Load Balancing (SLBC) works and then breaks down the details and explains why you might want to change some load balancing settings.

For information about IP sec load balancing, see FortiGate-6000 IPsec VPN on page 776.

FortiGate-6000 SLBC works as follows.

1. SLBC attempts to match all incoming sessions with a configured flow rule (see Load balancing and flow rules on page 768). If a session matches a flow rule, the session is directed according to the action setting of the flow rule. Usually flow rules send traffic that can't be load balanced to a specific FPC.
2. TCP, UDP, SCTP, ICMP (IPv4 only) and ESP (IPv4 only) sessions that do not match a flow rule are directed to the DP3 processors.
   The DP3 processors distribute sessions to the FPCs according to the load balancing method set by the `dp-load-distribution-method` option of the `config load-balance setting` command.
3. All other sessions are sent to the primary (or master) FPC.

Setting the load balancing method

The FortiGate-6000 load balances or distributes sessions based on the load balancing method set by the following command:

```
config load-balance setting
   set dp-load-distribution-method {to-master | src-ip | dst-ip | src-dst-ip | src-ip-
       sport | dst-ip-dport | src-dst-ip-sport-dport}
end
```

Where:

`to-master` directs all session to the primary FPC. For troubleshooting only and should not be used for normal operation. Directing all sessions to the primary FPC has a negative impact on performance.

`src-ip` distribute sessions across all FPCs according to their source IP address.

`dst-ip` distribute sessions statically distributed across all FPCs according to their destination IP address.

`src-dst-ip` distribute sessions across all FPCs according to their source and destination IP addresses.

`src-ip-sport` distribute sessions across all FPCs according to their source IP address and source port.

`dst-ip-dport` distribute sessions across all FPCs according to their destination IP address and destination port.

`src-dst-ipsport-dport` distribute sessions across all FPCs according to their source and destination IP address, source port, and destination port. This is the default load balance algorithm and represents true session-aware load balancing. Session aware load balancing takes all session information into account when deciding where to send new sessions and where to send additional packets that are part of an already established session.

The `src-ip` and `dst-ip` load balancing methods use layer 3 information (IP addresses) to identify and load balance sessions. All of the other load balancing methods (except for `to-master`) use both layer 3 and layer 4 information (IP addresses and port numbers) to identify a TCP and UDP session. The layer 3 and layer 4 load

balancing methods only use layer 3 information for other types of traffic (SCTP, ICMP, and ESP). If you enable GTP load balancing, the FortiGate-6000 uses Tunnel Endpoint Identifiers (TEIDs) to identify GTP sessions.

Flow rules for sessions that cannot be load balanced

Some traffic types cannot be load balanced. Sessions for traffic types that cannot be load balanced should normally be sent to the primary (or master) FPC by configuring flow rules for that traffic. You can also configure flow rules to send traffic that cannot be load balanced to specific FPCs.

Create flow rules using the `config loadbalance flow-rule` command. The default configuration uses this command to send IKE, GRE, session helper, Kerberos, BGP, RIP, IPv4 and IPv6 DHCP, PPTP, BFD, IPv4 multicast and IPv6 multicast to the primary FPC. You can view the default configuration of the `config loadbalance flow-rule` command to see how this is all configured. For example, the following configuration sends all IKE sessions to the primary FPC:

```
config load-balance flow-rule
   edit 1
      set status enable
      set vlan 0
      set ether-type ip
      set protocol udp
      set src-l4port 500-500
      set dst-l4port 500-500
      set action forward
      set forward-slot master
      set priority 5
      set comment "ike"
   next
   edit 2
      set status disable
      set vlan 0
      set ether-type ip
      set protocol udp
      set src-l4port 4500-4500
      set dst-l4port 0-0
      set action forward
      set forward-slot master
      set priority 5
      set comment "ike-natt src"
   next
   edit 3
      set status disable
      set vlan 0
      set ether-type ip
      set protocol udp
      set src-l4port 0-0
      set dst-l4port 4500-4500
      set action forward
      set forward-slot master
      set priority 5
      set comment "ike-natt dst"
   next
```

See Default configuration for traffic that cannot be load balanced on page 772 for a listing of all of the default flow rules.

Here is a list of protocols that are not load balanced, but sent to the primary FPC. You can create flow rules to change this behavior:

- IPv4 over IPv6
- IPv6 over IPv4
- IP over IP
- L2TP

Determining which FPC is operating as the primary FPC

You can use the `diagnose load-balance status` command to determine which FPC is operating as the primary FPC. The primary FPC is also responsible for dynamic routing.

The following example `diagnose load-balance status` output for a FortiGate-6300F shows that the FPC in slot 1 is the primary (master) FPC. The command output also shows the status of all of the FPCs in the FortiGate-6300F.

```
diagnose load-balance status
================================================================================
MBD SN: F6KF313E17900032
  Master FPC Blade: slot-1

     Slot  1: FPC6KF3E1790020
       Status:Working   Function:Active
       Link:      Base: Up          Fabric: Up
       Heartbeat: Management: Good   Data: Good
       Status Message:"Running"
     Slot  2: FPC6KF3E17900201
       Status:Working   Function:Active
       Link:      Base: Up          Fabric: Up
       Heartbeat: Management: Good   Data: Good
       Status Message:"Running"
     Slot  3: FPC6KF3E17900207
       Status:Working   Function:Active
       Link:      Base: Up          Fabric: Up
       Heartbeat: Management: Good   Data: Good
       Status Message:"Running"
     Slot  4: FPC6KF3E17900219
       Status:Working   Function:Active
       Link:      Base: Up          Fabric: Up
       Heartbeat: Management: Good   Data: Good
       Status Message:"Running"
     Slot  5: FPC6KF3E17900235
       Status:Working   Function:Active
       Link:      Base: Up          Fabric: Up
       Heartbeat: Management: Good   Data: Good
       Status Message:"Running"
     Slot  6: FPC6KF3E17900169
       Status:Working   Function:Active
       Link:      Base: Up          Fabric: Up
       Heartbeat: Management: Good   Data: Good
       Status Message:"Running"
```

GTP load balancing

You can use the following command to enable or disable GTP load balancing.

```
config load-balance setting
   set gtp-load-balance {disable | enable}
end
```

By default, this option is disabled and GTP load balancing is disabled. Instead, the following flow rule is enabled and GTP traffic is directed to the primary (master) FPC.

```
config load-balance flow-rule
    edit 17
        set status enable
        set ether-type ipv4
        set protocol udp
        set dst-l4port 546-546
        set dst-l4port 2123-2123
        set comment "gtp-c to master blade"
    next
end
```

When the `gtp-load-balance` option is enabled, the GTP load balancing is flow rule is disabled and the FortiGate-6000 directs GTP sessions to the DP3 processors where they are load balanced to the FPCs.

SSL VPN load balancing

FortiGate-6000s do not support load balancing SSL VPN sessions terminated by the FortiGate-6000. The recommended configuration is to direct SSL VPN sessions terminated by the FortiGate-6000 to the primary FPC. You can do this by enabling the following built-in SSL VPN flow rule.

SSL VPN sessions are sessions from an SSL VPN client to your configured SSL VPN server listening port.

```
config load-balance flow-rule
    edit 26
        set ether-type ip
        set protocol tcp
        set dst-l4port 10443-10443
        set forward-slot load-balance
        set comment "ssl vpn to master blade"
    next
end
```

This flow rule matches all sessions sent to the port 10443 (the default SSL VPN server listening port) and sends these sessions to the primary FPC. This should match all of your SSL VPN traffic if you are using the default SSL VPN server listening port. This flow rule also matches all other sessions using 10443 as the destination port so all of this traffic is also sent to the primary FPC.

If you change the SSL VPN server listening port

You must either create custom SSL VPN flow rules or modify the default SSL VPN if your SSL VPN server listening changes. For example, if you have changed the SSL VPN server listening port to 443 and set up your SSL VPN clients to only connect to port12 and port23 you can create the following flow rule:

```
config load-balance flow-rule
   edit 29
      set src-interface port12 port23
      set ethertype ip
      set protocol tcp
      set dst-l4port 443-443
    next
end
```

Default configuration for traffic that cannot be load balanced

The default FortiGate-6000 `configure load-balance flow-rule` command contains the recommended default rules for how the FortiGate-6000 handles traffic types that cannot be load balanced. All of these flow rules identify the traffic type using the options available in the command and direct the traffic to the primary (or master) FPC. The rules also include a comment that identifies the traffic type.

Most of the flow rules are enabled (`status` set to `enable`) and they will direct matching traffic to the primary FPC. However, the configuration does include some disabled flow rules. You can enable these flow rules if required for your network.

The CLI syntax below was created with the `show` command and just shows the configuration changes. All other options are set to their defaults. Flow rules with no `status` option are disabled be default. Also the default `forward-slot` setting is `master`, which directs matching traffic to the primary FPC.

```
config load-balance flow-rule
    edit 1
        set ether-type ip
        set protocol udp
        set src-l4port 88-88
        set comment "kerberos src"
    next
    edit 2
        set ether-type ip
        set protocol udp
        set dst-l4port 88-88
        set comment "kerberos dst"
    next

        edit 23
            set ether-type ipv4
            set protocol esp
            set comment "ipv4 esp"
        next
        edit 24
            set status enable
            set ether-type ip
            set protocol tcp
            set dst-l4port 1000-1000
            set comment "authd http to master blade"
        next
        edit 25
            set status enable
            set ether-type ip
            set protocol tcp
            set dst-l4port 1003-1003
            set comment "authd https to master blade"
        next
    end
```

FortiGate-6000 IPsec VPN

This chapter describes some common FortiGate-6000 IPsec VPN configurations.

IPsec VPN load balancing

You can use the following command to enable or disable IPsec VPN load balancing:

```
config load-balance setting
   config ipsec-load-balance {disable | enable}
end
```

By default IPsec VPN load balancing is enabled and the flow rules listed below are disabled. The FortiGate-6000 directs IPsec VPN sessions to the DP3 processors which load balances them among the FPCs.

However, with IPsec VPN load balancing enabled, the FortiGate-6000 will drop IPsec VPN sessions traveling between two IPsec tunnels because the two IPsec tunnels may be terminated on different FPCs. So if you have traffic entering the FortiGate-6000 from one IPsec VPN tunnel and leaving the FortiGate-6000 out another IPsec VPN tunnel you need to disable IPsec load balancing:

```
config load-balance setting
   config ipsec-load-balance disable
end
```

Disabling IPsec VPN load balancing in this way enables the following flow rules:

```
config load-balance flow-rule
    edit 21
        set ether-type ipv4
        set protocol udp
        set dst-l4port 500-500
        set comment "ipv4 ike"
    next
    edit 24
        set ether-type ipv4
        set protocol udp
        set dst-l4port 4500-4500
        set comment "ipv4 ike-natt dst"
    next
    edit 25
        set ether-type ipv4
        set protocol esp
        set comment "ipv4 esp"
    next
end
```

These flow rules should generally handle all IPsec VPN traffic. You can also adjust them or add your own flow rules if you have an IPsec VPN setup that is not compatible with the default flow rules.

Adding source and destination subnets to IPsec VPN phase 2 configurations

If your FortiGate-6000 configuration includes IPsec VPNs you should enhance your IPsec VPN Phase 2 configurations as described in this section. Because the FortiGate-6000 only allows 16-bit to 32-bit routes, you must add one or more destination subnets to your IPsec VPN phase 2 configuration for FortiGate-6000 v5.4.9 using the following command:

```
config vpn ipsec phase2-interface
   edit "to_fgt2"
      set phase1name <name>
      set src-subnet <IP> <netmask>
      set dst-subnet <IP> <netmask>
   end
```

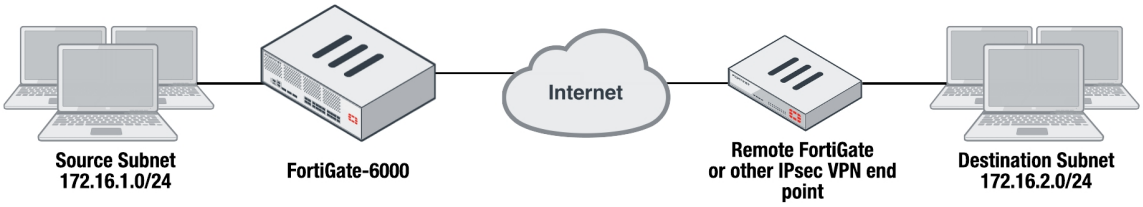
Where

`src-subnet` is the subnet protected by the FortiGate-6000 that you are configuring and from which users connect to the destination subnet. Configuring the source subnet is optional but recommended.

`dst-subnet` is the destination subnet behind the remote IPsec VPN endpoint. Configuring the destination subnet is required.

Example basic IPsec VPN Phase 2 configuration

In a simple configuration such as the one below with an IPsec VPN between two remote subnets you can just add the subnets to the phase 2 configuration.

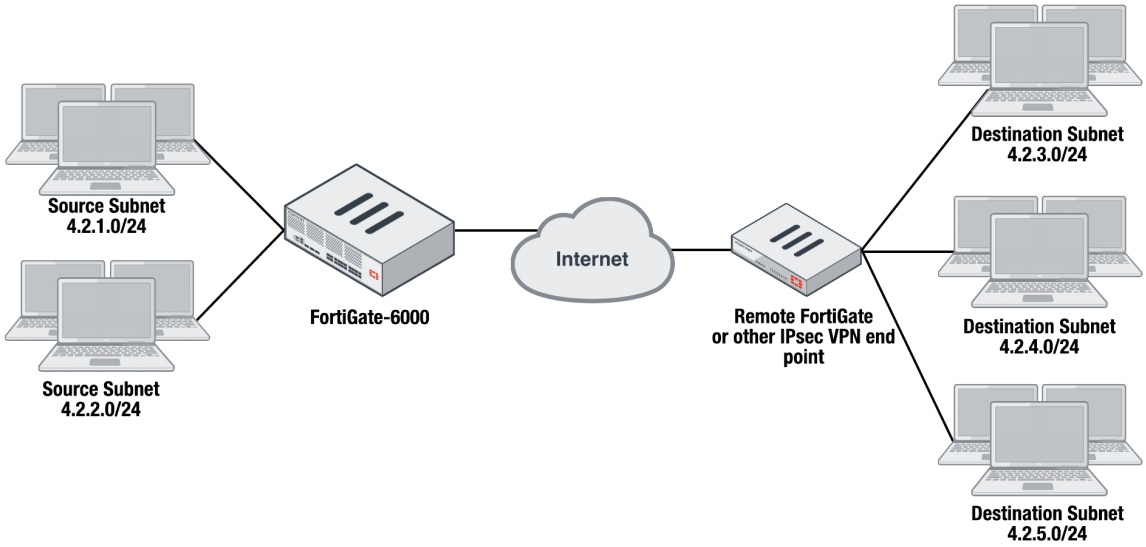


Enter the following command to add the source and destination subnets to the FortiGate-6000 IPsec VPN Phase 2 configuration.

```
config vpn ipsec phase2-interface
   edit "to_fgt2"
      set phase1name "to_fgt2"
      set src-subnet 172.16.1.0 255.255.255.0
      set dst-subnet 172.16.2.0 255.255.255.0
   end
```

Example multiple subnet IPsec VPN Phase 2 configuration

In a more complex configuration, such as the one below with a total of 5 subnets you still need to add all of the subnets to the Phase 2 configuration. In this case you can create a firewall address for each subnet and the addresses to address groups and add the address groups to the Phase 2 configuration.



Enter the following commands to create firewall addresses for each subnet.

```
config firewall address
   edit "local_subnet_1"
      set subnet 4.2.1.0 255.255.255.0
   next
   edit "local_subnet_2"
      set subnet 4.2.2.0 255.255.255.0
   next
   edit "remote_subnet_3"
      set subnet 4.2.3.0 255.255.255.0
   next
   edit "remote_subnet_4"
      set subnet 4.2.4.0 255.255.255.0
   next
   edit "remote_subnet_5"
      set subnet 4.2.5.0 255.255.255.0
   end
```

And then put the five firewall addresses into two firewall address groups.

```
config firewall addrgrp
   edit "local_group"
      set member "local_subnet_1" "local_subnet_2"
   next
   edit "remote_group"
      set member "remote_subnet_3" "remote_subnet_4" "remote_subnet_5"
   end
```

Now, use the firewall address groups in the Phase 2 configuration:

```
config vpn ipsec phase2-interface
   edit "to-fgt2"
      set phase1name "to-fgt2"
      set src-addr-type name
      set dst-addr-type name
      set src-name "local_group"
      set dst-name "remote_group"
```

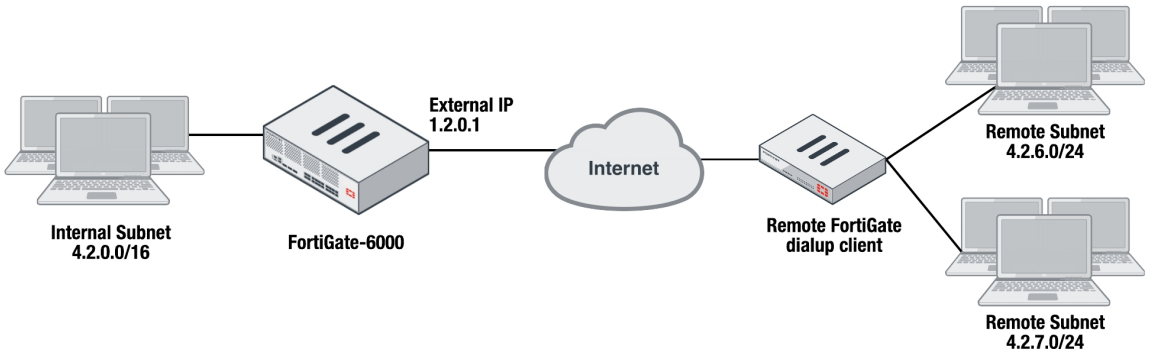
```
end
```

Configuring the FortiGate-6000 as a dialup IPsec VPN server

FortiGate-6000s running v5.4.9 can be configured as dialup IPsec VPN servers.

Example dialup IPsec VPN configuration

The following shows how to setup a dialup IPsec VPN configuration where the FortiGate-6000 acts as a dialup IPsec VPN server.



To configure the FortiGate-6000 as a dialup IPsec VPN server

Configure the phase1, set type to dynamic.

```
config vpn ipsec phase1-interface
   edit dialup-server
      set type dynamic
      set interface "v0020"
      set peertype any
      set psksecret < password>
   end
```

Configure the phase 2, to support dialup IPsec VPN, set the destination subnet to 0.0.0.0 0.0.0.0.

```
config vpn ipsec phase2-interface
   edit dialup-server
      set phase1name dialup-server
      set src-subnet 4.2.0.0 255.255.0.0
      set dst-subnet 0.0.0.0 0.0.0.0
   end
```

To configure the remote FortiGate as a dialup IPsec VPN client

The dialup IPsec VPN client should advertise its local subnet(s) using the phase 2 src-subnet option.

If there are multiple local subnets, create a phase 2 for each one. Each phase 2 only advertises one local subnet to the dialup IPsec VPN server. If more than one local subnet is added to the phase 2, only the first one is advertised to the server.

Dialup client configuration:

```
config vpn ipsec phase1-interface
   edit "to-fgt6k"
      set interface "v0020"
      set peertype any
      set remote-gw 1.2.0.1
      set psksecret <password>
   end
config vpn ipsec phase2-interface
   edit "to-fgt6k"
      set phase1name "to-fgt6k"
      set src-subnet 4.2.6.0 255.255.255.0
      set dst-subnet 4.2.0.0 255.255.0.0
   next
   edit "to-fgt6k-2"
      set phase1name "to-fgt6k"
      set src-subnet 4.2.7.0 255.255.255.0
      set dst-subnet 4.2.0.0 255.255.0.0
   end
```

FortiGate-6000 high availability (FGCP)

FortiGate-6000 supports FortiGate Clustering Protocol (FGCP) HA between two (and only two) identical FortiGate-6000 models. You can configure FortiGate-6000 HA in much the same way as any FortiGate HA setup except that you must use the HA1 and HA2 interfaces for HA heartbeat communication. Also, the heartbeat packets are VLAN-tagged and you can configure the VLANs used. Also, FortiGate-6000 HA only supports Active-Passive HA and even though the FortiGate-6000s are configured with multiple VDOMs they do not support virtual clustering.

During the FortiGate-6000 HA configuration you assign each of the FortiGate-6000s in the HA cluster a chassis ID of 1 or 2. The chassis IDs just allow you to identify individual FortiGate-6000s and do not influence primary unit selection.

Example FortiGate-6000 HA configuration

In a FortiGate-6000 FGCP HA configuration, the primary (or master) FortiGate-6000 processes all traffic. The backup FortiGate-6000 operates in hot standby mode. The FGCP synchronizes the configuration, active sessions, routing information, and so on to the backup FortiGate-6000. If the primary FortiGate-6000 fails, traffic automatically fails over to the backup.

The FGCP selects the primary FortiGate-6000 based on standard FGCP primary unit selection:

- Connected monitored interfaces
- Age
- Device Priority
- Serial Number

In most cases, if everything is connected and operating normally, the FortiGate-6000 with the highest serial number becomes the primary FortiGate-6000. You can set the device priority higher on one of the FortiGate-6000s if you want to it to become the primary unit. You can also enable override along with setting a higher device priority to make sure the same FortiGae-6000 always becomes the primary FortiGate-6000.

Session terminated by the cluster include management sessions (such as HTTPS connections to the FortiGate GUI or SSH connection to the CLI as well as SNMP and logging and so on). Also included in this category are IPsec VPN, SSL VPN, sessions terminated by the cluster, and explicit proxy sessions. In general, whether or not session-pickup is enabled, these sessions do not failover and have to be restarted.

Before you begin configuring HA

Before you begin, the FortiGate-6000s should be running the same FortiOS firmware version and interfaces should not be configured to get their addresses from DHCP or PPPoE. Register and apply licenses to each FortiGate-6000 before setting up the HA cluster. This includes licensing for FortiCare, IPS, AntiVirus, Web Filtering, Mobile Malware, FortiClient, FortiCloud, and additional virtual domains (VDOMs). Both FortiGate-6000s in the cluster must have the same level of licensing for FortiGuard, FortiCloud, FortiClient, and VDOMs. FortiToken licenses can be added at any time because they are synchronized to all cluster members.

On each FortiGate-6000, make sure the configurations of the FPCs are synchronized before starting to configure HA. You can use the following command to verify the configuration status of the FPCs. The following example shows the results from a FortiGate-6300F.

```
diagnose sys confsync showchsum | grep all
```

```
all: c0 68 d2 67 e1 23 d9 3a 10 50 45 c5 50 f1 e6 8e
all: c0 68 d2 67 e1 23 d9 3a 10 50 45 c5 50 f1 e6 8e
all: c0 68 d2 67 e1 23 d9 3a 10 50 45 c5 50 f1 e6 8e
all: c0 68 d2 67 e1 23 d9 3a 10 50 45 c5 50 f1 e6 8e
all: c0 68 d2 67 e1 23 d9 3a 10 50 45 c5 50 f1 e6 8e
all: c0 68 d2 67 e1 23 d9 3a 10 50 45 c5 50 f1 e6 8e
all: c0 68 d2 67 e1 23 d9 3a 10 50 45 c5 50 f1 e6 8e
```

If the FPCs are synchronized, the listed checksums should all be the same.

You can also use the following command to list the FPCs that are synchronized. The example output, for a FortiGate-6300F, shows all six FPCs have been configured for HA and added to the cluster.

```
diagnose sys confsync status | grep in_sync
F6KF313E17900031, Slave, uptime=232441.23, priority=2, slot_id=1:0, idx=0, flag=0x10, in_sync=1
F6KF313E17900031, Slave, uptime=232441.23, priority=2, slot_id=1:0, idx=0, flag=0x10, in_sync=1
F6KF313E17900031, Slave, uptime=232441.23, priority=2, slot_id=1:0, idx=0, flag=0x10, in_sync=1
F6KF313E17900031, Slave, uptime=232441.23, priority=2, slot_id=1:0, idx=0, flag=0x10, in_sync=1
F6KF313E17900031, Slave, uptime=232441.23, priority=2, slot_id=1:0, idx=0, flag=0x10, in_sync=1
F6KF313E17900031, Master, uptime=232441.23, priority=1, slot_id=1:0, idx=0, flag=0x10, in_sync=1
F6KF313E17900031, Slave, uptime=232441.23, priority=2, slot_id=1:0, idx=0, flag=0x10, in_sync=1
FPC6KF3E17900209, Slave, uptime=231561.99, priority=24, slot_id=1:6, idx=6, flag=0x24, in_sync=1
FPC6KF3E17900215, Slave, uptime=231524.81, priority=22, slot_id=1:4, idx=7, flag=0x24, in_sync=1
FPC6KF3E17900217, Slave, uptime=232289.83, priority=120, slot_id=1:5, idx=8, flag=0x24, in_sync=1
FPC6KF3E17900229, Slave, uptime=232271.59, priority=118, slot_id=1:3, idx=10, flag=0x24, in_sync=1
FPC6KF3E17900230, Slave, uptime=232330.19, priority=116, slot_id=1:1, idx=11, flag=0x24, in_sync=1
FPC6KF3E17900291, Slave, uptime=232314.29, priority=117, slot_id=1:2, idx=13, flag=0x24, in_sync=1
```

In this command output `in_sync=1` means the FPC is synchronized with the management board and `in_sync=0` means the FPC is not synchronized.

Connect the HA1 and HA2 interfaces for HA heartbeat communication

HA heartbeat communication between FortiGate-6000s happens over the 10Gbit HA1 and HA2 interfaces. To set up HA heartbeat connections:

- Connect the HA1 interfaces of the two FortiGate-6000s together either with a direct cable connection, or using a switch.
- Connect the HA2 interfaces in the same way.

Heartbeat packets are VLAN packets with VLAN ID 999 and ethertype 9890. The MTU value for the HA1 and HA2 interfaces is 1500. You can use the following commands to change the HA heartbeat packet VLAN ID and ethertype values if required for your switches. You must change these settings on each FortiGate-6000. By default the HA1 and HA2 interface heartbeat packets use the same VLAN IDs.

```
config system ha
   set hbdev-vlan-id <vlan>
   set hbdev-second-vlan-id <vlan>
   set ha-eth-type <eth-type>
end
```

Using separate connections for HA1 and HA2 is recommended for redundancy. If you are using switches, it is also recommended that these switches be dedicated to HA heartbeat communication and not used for other traffic.

If you use the same switch for both HA1 and HA2, separate the HA1 and HA2 traffic on the switch and set the heartbeat traffic on the HA1 and HA2 Interfaces to have different VLAN IDs. For example, use the following command to set the heartbeat traffic on HA1 to use VLAN ID 777 and the heartbeat traffic on HA2 to use VLAN ID 888:

```
config system ha
  set hbdev-vlan-id 777
  set hbdev-second-vlan-id 888
end
```

If you don't set different VLAN IDs for the HA1 and HA2 heartbeat packets, q-in-q must be enabled on the switch.

Sample switch configuration for a Cisco Catalyst switch. This configuration sets the interface speeds, configures the switch to allow vlan 999, and enables trunk mode:

```
##interface config
interface TenGigabitEthernet1/0/5
description Chassis1 M1
switchport trunk allowed vlan 999
switchport mode trunk
```

If you are using one switch for both HA1 and HA2 connections, the configuration would be the same except you would add q-in-q support and two different VLANs, one for HA1 traffic and one for HA2 traffic.

For the HA1 connections:

```
interface Ethernet1/5
description QinQ Test
switchportmode dot1q-tunnel
switchport access vlan 888
spanning-tree port type edge
```

For the HA2 connections:

```
interface Ethernet1/5
description QinQ Test
switchport mode dot1q-tunnel
switchport access vlan 880
spanning-tree port type edge
```

HA packets must have the configured VLAN tag (default 999). If the switch removes or changes this tag, HA heartbeat communication will not work and the cluster will form a split brain configuration. In effect two clusters will form, one in each FortiGate-6000, and network traffic will be disrupted.

HA configuration steps

Use the following steps to setup the configuration for HA between two FortiGate-6000s.

Setting up HA

1. Log into the CLI of one of the FortiGate-6000s and enter the following:

```
config system ha
   set group-id <id>
   set group-name <name>
   set password <password>
   set mode a-p
   set hbdev ha1 50 ha2 100
   set chassis-id 1
   set hbdev-vlan-id 999
   set hbdev-second-vlan-id 998
   set session-pickup enable
   set override enable
end
```

   This adds basic HA settings.

2. Repeat the same HA configuration settings on the second FortiGate-6000 except set the chassis ID to 2.

```
config system ha
   set group-id <id>
   set group-name <name>
   set password <password>
   set mode a-p
   set hbdev ha1 50 ha2 100
   set chassis-id 2
   set hbdev-vlan-id 999
   set hbdev-second-vlan-id 998
   set session-pickup enable
   set override enable
end
```

3. Connect the HA1 interfaces and the HA2 interfaces of the two FortiGate-6000s together as described in HA configuration steps on page 783.
   The FortiGate-6000s negotiate to establish an HA cluster. You may temporarily lose connectivity with the FortiGate-6000s as the HA cluster negotiates and the FGCP changes the MAC addresses of the FortiGate-6000 interfaces. To be able to reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate (or just deleting all ARP table entries). You may be able to delete the ARP table of your management PC from a command prompt using a command similar to `arp -d`.
4. When you can log into the primary FortiGate-6000, enter the following command to confirm that the cluster has formed:

```
diagnose sys ha status
==========================================================================
MBD SN: F6KF313E17900032
HA information
Statistics
       traffic.local = s:0 p:10925739 b:2573484016
       traffic.total = s:0 p:10925890 b:2573511615
       activity.fdb  = c:0 q:0

Model=6301F, Mode=2 Group=1 Debug=0
nvcluster=1, ses_pickup=1, delay=0

[Debug_Zone HA information]
HA group member information: is_manage_master=1.
```

```
F6KF313E17900032: Master, serialno_prio=0, usr_priority=128, host-
name=F6KF313E17900032
F6KF313E17900031:  Slave, serialno_prio=1, usr_priority=128,
hostname=F6KF313E17900031

[Kernel HA information]
vcluster 1, state=work, master_ip=10.101.11.20, master_id=0:
F6KF313E17900032: Master, ha_prio/o_ha_prio=0/0
F6KF313E17900031:  Slave, ha_prio/o_ha_prio=1/1
```

You can also check the status with the `get system ha status` command and `diagnose sys ha dump-by group`.

Managing individual FPCs in HA mode

In some cases, you may want to connect to an individual FPC in one of the FortiGate-6000s in the HA cluster. For example, you may want to view the traffic being processed by the FPC in slot 3 of chassis 2. You can connect to the GUI or CLI of individual FPCs in the FortiGate-6000 using the management IP address with a special port number.

For example, if the management IP address is 1.1.1.1 you can browse to https://1.1.1.1:44313 to connect to the FPC in chassis 2 slot 3. The special port number (in this case 44323) is a combination of the service port, chassis ID, and slot number. The special port numbers are the same as those listed under Getting started with FortiGate-6000 on page 754 with the addition of the number two for FPCs in the FortiGate-6000 with chassis ID 2.

For example:

- To connect to the GUI of the FPC in chassis 2 slot 6 using HTTPS you would browse to https://1.1.1.1:44326.
- To send an SNMP query to the FPC in chassis 2 slot 4 use the port number 16124.

The formula for calculating the special port number is based on Chassis ID. CH1 = Chassis ID1, CH2 = Chassis ID2. The formula is: service_port x 100 + (chassis_id – 1) x 20 + slot_id.

Firmware upgrade

Both management boards and all of the FPCs in a FortiGate-6000 HA cluster run the same firmware image. You upgrade the firmware from the GUI or CLI by logging into the primary FortiGate-6000 and installing the firmware image.

If `uninterruptable-upgrade` and `session-pickup` are enabled, firmware upgrades should only cause a minimal traffic interruption. Use the following command to enable these settings (they should be enabled by default). These settings are synchronized.

```
config system ha
   set uninterruptable-upgrade enable
   set session-pickup enable
end
```

When these settings are enabled, the primary FortiGate-6000 management board uploads firmware to the backup FortiGate-6000 management board. The backup management board uploads the firmware to all of the FPCs in the backup FortiGate-6000. Then the management board and all of the FPCs in the backup ForiGate-6000 upgrade their firmware and reboot and resynchronize.

Then all traffic fails over to the backup FortiGate-6000 which becomes the new primary FortiGate-6000. Then the management board and the FPCs in the new backup FortiGate-6000 upgrade their firmware and rejoin the cluster. Unless override is enabled, the new primary FortiGate-6000 continues to operate as the primary FortiGate-6000.

Normally you would want to enable `uninterruptable-upgrade` to minimize traffic interruptions. But `unterruptable-upgrade` does not have to be enabled. In fact, if a traffic interruption is not going to cause any problems you can disable `unterruptable-upgrade` so that the firmware upgrade process takes less time.

Distributed clustering

FortiGate-6000 HA supports separating the FortiGate-6000s in different physical locations. Distributed FortiGate-6000 HA clustering (or geographically distributed FortiGate-6000 HA or geo clustering) can involve two FortiGate-6000s in different rooms in the same building, different buildings in the same location, or even different geographical sites such as different cities, countries or continents.

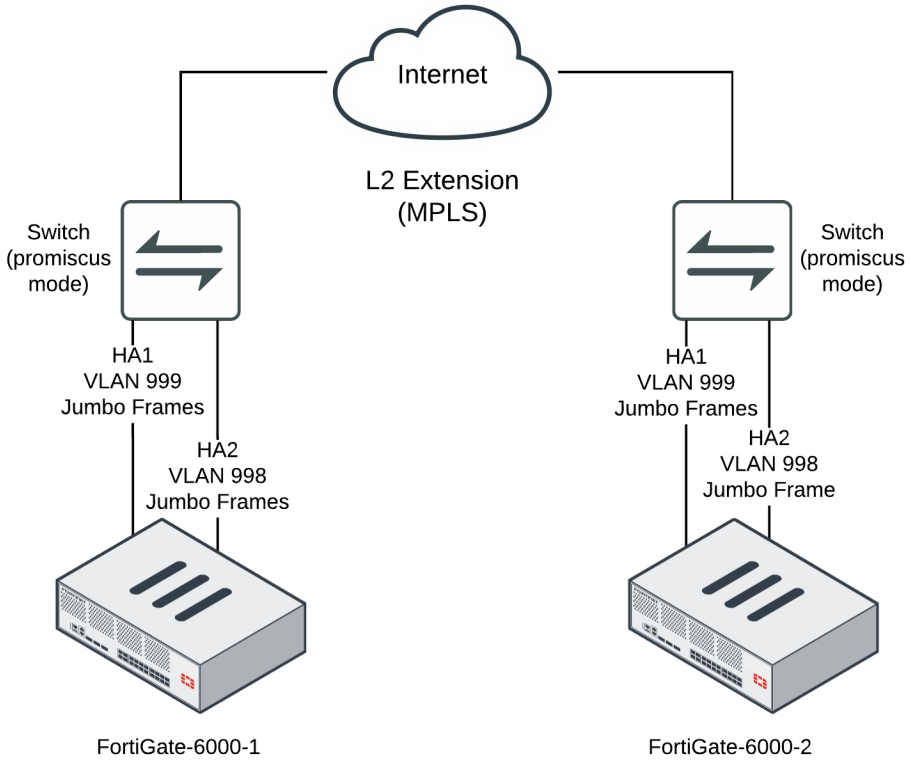
Just like any FortiGate-6000 HA configuration, distributed FortiGate-6000 HA requires heartbeat communication between the FortiGate-6000s over the HA1 and HA2 interfaces. In a distributed FortiGate-6000 HA configuration this heartbeat communication can take place over the Internet or over other transmission methods including satellite linkups.

Most Data Center Interconnect (DCI) or MPLS-based solutions that support layer 2 extensions and VLAN tags between the remote data centers should also support HA heartbeat communication between the FortiGates in the distributed locations. Using VLANs and switches in promiscuous mode to pass all traffic between the locations can also be helpful.

You cannot change HA heartbeat IP addresses, so the heartbeat interfaces have to be able to communication over the same subnet.

The HA1 and HA2 interface traffic must be separated. You can do this by using separate channels for each interface or by configuring the HA1 and HA2 interfaces to use different VLANs.

Example FortiGate-6000 distributed clustering configuration



Because of the possible distance between sites, it may take a relatively long time for heartbeat packets to be transmitted between the FortiGate-6000s. This could lead to a split brain scenario. To avoid a split brain scenario you can modify heartbeat timing so that the cluster expects extra time between heartbeat packets. As a general rule, set the heartbeat failover time (`hb-interval`) to be longer than the max latency or round trip time (RTT). You could also increase the `hb-lost-threshold` to tolerate losing heartbeat packets if the network connection is less reliable.

In addition you could use different link paths for heartbeat packets to optimize HA heartbeat communication. You could also configure QoS on the links used for HA heartbeat traffic to make sure heartbeat communication has the highest priority.

Modifying heartbeat timing

If the FortiGate-6000s in the HA cluster do not receive heartbeat packets on time, the FortiGate-6000s in the HA configuration may each determine that the other FortiGate-6000 has failed. HA heartbeat packets may not be sent on time because of network issues. For example, if the HA1 and HA2 communications links between the FortiGate-6000s become too busy to handle the heartbeat traffic. Also, in a distributed clustering configuration the round trip time (RTT) between the FortiGate-6000s may be longer the expected time between heartbeat packets.

In addition, if the FortiGate-6000s becomes excessively busy, they may delay sending heartbeat packets.

Even with these delays, the FortiGate-6000 HA cluster can continue to function normally as long as the HA heartbeat configuration supports longer delays between heartbeat packets and more missed heartbeat packets.

You can use the following commands to configure heartbeat timing:

```
config system ha
   set hb-interval <interval_integer>
   set hb-lost-threshold <threshold_integer>
   set hello-holddown <holddown_integer>
end
```

Changing the heartbeat interval

The heartbeat interval is the time between sending HA heartbeat packets. The heartbeat interval range is 1 to 20 (100*ms). The heartbeat interval default is 2 (200 ms).

A heartbeat interval of 2 means the time between heartbeat packets is 200 ms. Changing the heartbeat interval to 5 changes the time between heartbeat packets to 500 ms (5 * 100ms = 500ms).

Use the following CLI command to increase the heartbeat interval to 10:

```
config system ha
   set hb-interval 10
end
```

Changing the lost heartbeat threshold

The lost heartbeat threshold is the number of consecutive heartbeat packets that a FortiGate does not receive before assuming that a failure has occurred. The default value of 6mean that if a FortiGate-6000 does not receive 6 heartbeat packets it determines that the other FortiGate-6000 in the cluster has failed. The range is 1 to 60 packets.

The lower the `hb-lost-threshold`, the faster a FortiGate-6000 HA configuration responds when a failure occurs. However, sometimes heartbeat packets may not be received because the other FortiGate-6000 is very busy or because of network conditions. This can lead to a false positive failure detection. To reduce these false positives you can increase the `hb-lost-threshold`.

Use the following command to increase the lost heartbeat threshold to 12:

```
config system ha
   set hb-lost-threshold 12
end
```

Adjusting the heartbeat interval and lost heartbeat threshold

The heartbeat interval combines with the lost heartbeat threshold to set how long a FortiGate-6000 waits before assuming that the other FortiGate-6000 has failed and is no longer sending heartbeat packets. By default, if a FortiGate-6000 does not receive a heartbeat packet from a cluster unit for 6 * 200 = 1200 milliseconds or 1.2 seconds the FortiGate-6000 assumes that the other FortiGate-6000 has failed.

You can increase both the heartbeat interval and the lost heartbeat threshold to reduce false positives. For example, increasing the heartbeat interval to 20 and the lost heartbeat threshold to 30 means a failure will be assumed if no heartbeat packets are received after 30 * 2000 milliseconds = 60,000 milliseconds, or 60 seconds.

Use the following command to increase the heartbeat interval to 20 and the lost heartbeat threshold to 30:

```
config system ha
```

```
    set hb-lost-threshold 20
    set hb-interval 30
end
```

Changing the time to wait in the hello state

The hello state hold-down time is the number of seconds that a FortiGate-6000 waits before changing from hello state to work state. After a failure or when starting up, FortiGate-6000s in HA mode operate in the hello state to send and receive heartbeat packets to find each other and form a cluster. A FortiGate-6000 should change from the hello state to work state after it finds the FortiGate-6000 to form a cluster with. If for some reason the FortiGate-6000s cannot find each other during the hello state both FortiGate-6000s may assume that the other one has failed and each could form separate clusters of one FortiGate-6000. The FortiGate-6000s could eventually find each other and negotiate to form a cluster, possibly causing a network interruption as they re-negotiate.

One reason for a delay of the FortiGate-6000s finding each other could be the FortiGate-6000s are located at different sites or for some other reason communication is delayed between the heartbeat interfaces. If you find that your FortiGate-6000s leave the hello state before finding each other you can increase the time that they wait in the hello state. The hello state hold-down time range is 5 to 300 seconds. The hello state hold-down time default is 20 seconds.

Use the following command to increase the time to wait in the hello state to 1 minute (60 seconds):

```
config system ha
    set hello-holddown 60
end
```

Session failover (session-pickup)

Session failover means that after a failover, communication sessions resume on the new primary FortiGate-6000 with minimal or no interruption. Two categories of sessions need to be resumed after a failover:

- Sessions passing through the cluster
- Sessions terminated by the cluster

If sessions pickup is enabled, during cluster operation the primary FortiGate-6000 informs the backup FortiGate-6000 of changes to the primary FortiGate-6000 connection and state tables for TCP and UDP sessions passing through the cluster, keeping the backup FortiGate-6000 up-to-date with the traffic currently being processed by the cluster.

After a failover, the new primary FortiGate-6000 recognizes open sessions that were being handled by the cluster. The sessions continue to be processed by the new primary FortiGate-6000 and are handled according to their last known state.

Session-pickup has some limitations. For example, the FGCP does not support session failover for sessions being scanned by proxy-based security profiles. Session failover is supported for sessions being scanned by flow-based security profiles; however, flow-based sessions that fail over are not inspected after they fail over.

Sessions terminated by the cluster include management sessions (such as HTTPS connections to the FortiGate GUI or SSH connection to the CLI as well as SNMP and logging, and so on). Also included in this category are IPsec and SSL VPN sessions terminated by the cluster and explicit proxy sessions. In general, whether or not session-pickup is enabled, these sessions do not failover and have to be restarted.

Enabling session pickup for TCP and UDP sessions

To enable session-pickup, from the CLI enter:

```
config system ha
   set session-pickup enable
end
```

When session-pickup is enabled, sessions in the primary FortiGate-6000 TCP and UDP session tables are synchronized to the backup FortiGate-6000. As soon as a new TCP or UDP session is added to the primary FortiGate-6000 session table, that session is synchronized to the backup FortiGate-6000. This synchronization happens as quickly as possible to keep the session tables synchronized.

If the primary FortiGate-6000 fails, the new primary FortiGate-6000 uses its synchronized session tables to resume all TCP and UDP sessions that were being processed by the former primary FortiGate-6000 with only minimal interruption. Under ideal conditions all TCP and UDP sessions should be resumed. This is not guaranteed though and under less than ideal conditions some sessions may need to be restarted.

If session pickup is disabled

If you disable session pickup, the FortiGate-6000 HA cluster does not keep track of sessions and after a failover, active sessions have to be restarted or resumed. Most session can be resumed as a normal result of how TCP and UDP resumes communication after any routine network interruption.

The session-pickup setting does not affect session failover for sessions terminated by the cluster.

If you do not require session failover protection, leaving session pickup disabled may reduce CPU usage and reduce HA heartbeat network bandwidth usage. Also, if your FortiGate-6000 HA cluster is mainly being used for traffic that is not synchronized (for example, for proxy-based security profile processing) enabling session pickup is not recommended since most sessions will not be failed over anyway.

FortiGate-6000 v5.4.9 special features and limitations

This section describes special features and limitations for FortiGate-6000 v5.4.9.

Remote console limitations

Some console input may not function as expected. For example, when remotely connecting to an FPC console using Telnet, when viewing the BIOS menu, pressing the H key to display BIOS menu help does not always work as expected.

Default management VDOM

By default the FortiGate-6000 configuration includes a management VDOM named mgmt-vdom.The ha1, ha2, mgmt1, mgmt2, and mgmt3 interfaces are in mgmt-vdom and all other interfaces are in the root VDOM. For the FortiGate-6000 system to operate normally, mgmt-vdom must always be the management VDOM. You also must not remove interfaces from this VDOM. You can change the IP addresses of the interfaces in mgmt-vdom, allow the required management services, and add routes as required for management traffic.

You have full control over the configurations of other FortiGate-6000 VDOMs.

Maximum number of LAGs

FortiGate-6000 systems support up to 16 link aggregation groups (LAGs). This includes both normal link aggregation groups and redundant interfaces.

Firewall

TCP or UDP sessions with NAT enabled that are expected to be idle for more than the distributed processing normal TCP timer (which is 3605 seconds) will timeout. If you encounter this problem you can use the following command to increase the TCP timer:

```
config system global
   set dp-tcp-normal-timer <timer>
end
```

IP Multicast

IPv4 and IPv6 Multicast traffic is only sent to the primary FPC. This is controlled by the following configuration:

```
config load-balance flow-rule
   edit 15
      set status enable
      set vlan 0
      set ether-type ipv4
      set src-addr-ipv4 0.0.0.0 0.0.0.0
      set dst-addr-ipv4 224.0.0.0 240.0.0.0
      set protocol any
      set action forward
      set forward-slot master
      set priority 5
      set comment "ipv4 multicast"
   next
   edit 16
      set status enable
      set vlan 0
```

```
      set ether-type ipv6
      set src-addr-ipv6 ::/0
      set dst-addr-ipv6 ff00::/8
      set protocol any
      set action forward
      set forward-slot master
      set priority 5
      set comment "ipv6 multicast"
   end
```

High Availability

Only the HA1 and HA2 interfaces are used for the HA heartbeat communication.

If you use the same switch for both HA1 and HA2, separate the HA1 and HA2 traffic on the switch and set the heartbeat traffic on the HA1 and HA2 Interfaces to have different VLAN IDs. For example, the following command set the HA1 interface to use VLAN 999 and the HA2 interface to use VLAN 998:

```
config system ha
   set hbdev-vlan-id 999
   set hbdev-second-vlan-id 998
end
```

If you don't set different VLAN IDs for the HA1 and HA2 heartbeat packets, q-in-q must be enabled on the switch.

Fortinet recommends the following HA configuration:

```
config system ha
   set group-id <id>
   set group-name <name>
   set mode a-p
   set password <password>
   set hbdev ha1 50 ha2 100
   set chassis-id 2
   set hbdev-vlan-id 999
   set hbdev-second-vlan-id 998
   set session-pickup enable
   set override enable
end
```

Other HA options can be set as required for your network.

The following FortiOS HA features are not supported or are supported differently by FortiGate-6000 v5.4.9:

- Active-active HA is not supported.
- The range for the HA `group-id` is 0 to 15.
- Failover logic for FortiGate-6000 v5.4.9 HA is the same as FGCP for other FortiGate clusters.
- HA heartbeat configuration is specific to FortiGate-6000 systems and differs from standard HA.
- FortiGate Session Life Support Protocol (FGSP) HA (also called standalone session synchronization) is not supported.

FortiOS features that are not supported by FortiGate-6000 v5.4.9

The following mainstream FortiOS 5.4.9 features are not supported by the FortiGate-6000 v5.4.9:

- Hardware switch
- Switch controller
- WiFi controller

- IPv4 over IPv6, IPv6 over IPv4, IPv6 over IPv6 features
- GRE tunneling is only supported after creating a load balance flow rule, for example:

```
config load-balance flow-rule
   edit 0
      set status enable
      set vlan 0
      set ether-type ip
      set protocol gre
      set action forward
      set forward-slot master
      set priority 3
   end
```

- Only the FortiGate-6301F and the FortiGate-6501F support hard disk features such as WAN optimization, web caching, explicit proxy content caching, disk logging, and GUI-based packet sniffing.
- The management interfaces (mgmt1-3) do not support device detection for the networks they are connected to.

IPsec VPN tunnels terminated by the FortiGate-6000

This section lists FortiGate-6000 limitations for IPsec VPN tunnels terminated by the FortiGate-6000:

- Interface-based IPsec VPN is recommended.
- Policy based IPsec VPN is supported, but requires creating flow-rules for each Phase 2 selector.
- Dynamic routing and policy routing is not supported for IPsec interfaces.
- IPsec static routes don't consider distance, weight, priority settings. IPsec static routes are always installed in the routing table, regardless of the tunnel state.
- IPsec tunnels are not load-balanced across the FPCs, all IPsec tunnel sessions are sent to the primary FPC.
- IPsec VPN dialup or dynamic tunnels require a flow rule that sends traffic destined for IPsec dialup IP pools to the primary FPC.
- In an HA configuration, IPsec SAs are not synchronized to the backup chassis. IPsec SAs are renegotiated after a failover.
- IPsec VPN tunnel creation may be lower than expected due to DP3 limitations.

SSL VPN

Sending all SSL VPN sessions to the primary (master) FPC is recommended. You can do this by:

- Creating a flow rule that sends all sessions that use the SSL VPN destination port and IP address to the primary FPC.
- Creating flow rules that send all sessions that use the SSL VPN IP pool addresses to the primary FPC.

Traffic shaping

You can only configure traffic shaping from the CLI. Each FPC applies traffic shaping quotas independently. Traffic is first load balanced to the FPCs and then traffic shaping is applied by the FPC to the traffic load balanced to it.This may result in traffic shaping allowing more traffic than expected.

DDoS quotas

Each FPC applies DDoS quotas independently. Traffic is first load balanced to the FPCs and then DDoS quotas are applied by the FPC to the traffic load balanced to it. This may result in DDoS quotas being less effective than expected.

Sniffer mode (one-arm sniffer)

One-arm sniffer mode is only supported after creating a load balance flow rule to direct sniffer traffic to a specific FPC.

FortiGuard Web filtering and Spam filtering

The FortiGate-6000 sends all FortiGuard web filtering and spam filtering rating queries through a management interface from the management VDOM.

Log messages include a slot field

An additional "slot" field has been added to log messages to identify the FPC that generated the log.

Special notice for new deployment connectivity testing

Only the management board can successfully ping external IP addresses. During a new deployment, while performing connectivity testing from the Fortigate-6000, make sure to run `execute ping` tests from the management board and not from an FPC. See Using data interfaces for management traffic on page 758 for information about changes to this limitation.

Dedicated management interfaces not supported

The FortiGate-6000 does not support configuring dedicated management interfaces using the `config system dedicated-mgmt` command.

FortiGate-6000 load balancing commands

The most notable difference between a FortiGate-6000 and other FortiGates are the commands described in this section for configuring load balancing. The following commands are available:

```
config load-balance flow-rule
config load-balance setting
```

In most cases you do not have to use these commands. However, they are available to customize some aspects of load balancing.

FortiGate-6000 and FortiGate-7000 have the commands described in this chapter in common. Some of the options described in this section may not apply in the same way on these two platforms. These differences are noted in the descriptions. For example, the generic term "worker" maps to an FPC in a FortiGate-6000 and an FPM in a FortiGate-7000.

config load-balance flow-rule

Use this command to add FortiGate-6000 or FortiGate-7000 flow rules that add exceptions to how matched traffic is processed. Specifically you can use these rules to match a type of traffic and control whether the traffic is forwarded or blocked. And if the traffic is forwarded you can specify whether to forward the traffic to a specific slot or slots. Unlike firewall policies, load-balance rules are not stateful so for bi-directional traffic, you may need to define two flow rules to match both traffic directions (forward and reverse).

Syntax

```
config load-balance flow-rule
   edit 0
      set status {disable | enable}
      set src-interface <interface-name> [<interface-name>...]
      set vlan <vlan-id>
      set ether-type {any | arp | ip | ipv4 | ipv6}
      set src-addr-ipv4 <ip4-address> <netmask>
      set dst-addr-ipv4 <ip4-address> <netmask>
      set src-addr-ipv6 <ip6-address> <netmask>
      set dst-addr-ipv6 <ip6-address> <netmask>
      set protocol {any | icmp | icmpv6 | tcp | udp | igmp | sctp | gre | esp | ah | ospf
          | pim | vrrp}
      set src-l4port <start>[-<end>]
      set dst-l4port <start>[-<end>]
      set tcp-flag
      set action {forward | mirror-ingress stats | drop}
      set mirror-interface <interface-name>
      set forward-slot {master | all | load-balance | <FPM# or FPC#>}
      set priority <number>
      set comment <text>
   end
```

status {disable | enable}

Enable or disable this flow rule. Default for a new flow-rule is disable.

src-interface <interface-name> [interface-name>...}

The names of one or more FIM interface front panel interfaces accepting the traffic to be subject to the flow rule.

vlan <vlan-id>

If the traffic matching the rule is VLAN traffic, enter the VLAN ID used by the traffic.

ether-type {any | arp | ip | ipv4 | ipv6}

The type of traffic to be matched by the rule. You can match any traffic (the default) or just match ARP, IP, or IPv4 traffic.

{src-addr-ipv4 | dst-addr-ipv4} <ipv4-address> <netmask>

The source and destination address of the traffic to be matched. The default of `0.0.0.0 0.0.0.0` matches all traffic. Available if `ether-type` is set to `ipv4`.

{src-addr-ipv6 | dst-addr-ipv6} <ip-address> <netmask>

The source and destination address of the traffic to be matched. The default of `::/0` matches all traffic. Available if `ether-type` is set to `ipv6`.

protocol {any | icmp | tcp | udp | igmp | sctp | gre | esp | ah | ospf | pim | vrrp}

If `ether-type` is set to `ip`, `ipv4`, or `ipv6`, specify the protocol of the IP, IPv4, or IPv6 traffic to match the rule. The default is `any`.

{src-l4port | dst-l4port} <start>[-<end>]

Specify a source port range and a destination port range. This option appears for some protocol settings. For example if protocol is set to tcp or udp. The default range is 0-0.

action {forward | mirror-ingress | stats | drop}

How to handle matching packets. They can be dropped, forwarded to another destination or you can record statistics about the traffic for later analysis. You can combine two or three settings in one command for example, you can set `action` to both `forward` and `stats` to forward traffic and collect statistics about it. Use `append` to add multiple options.

The default action is `forward`.

The `mirror-ingress` option copies (mirrors) all ingress packets that match this flow rule and sends them to the interface specified with the `mirror-interface` option.

set mirror-interface <interface-name>

The name of the interface to send packets matched by this flow-rule when `action` is set to `mirror-ingress` or `mirror-egress`.

forward-slot {master | all | load-balance | <FPC#>}

The slot that you want to forward the traffic that matches this rule to.

`master` forwards the primary FPM or FPC.

`all` means forward the traffic to all slots.

`load-balance` means use the default load balancing configuration to handle this traffic.

`<FPM# or FPC#>` allows you to forward the matching traffic to a specific FPC (FortiGate-6000) or FPM module (FortiGate-7000). For example, FPC3 is the FortiGate-6000 FPC in slot 3. FPM3 is the FortiGate-7000 FPM module in slot 3.

priority <number>

Set the priority of the flow rule in the range 1 (highest priority) to 10 (lowest priority). Higher priority rules are matched first. You can use the priority to control which rule is matched first if you have overlapping rules.

comment <text>

Optionally add a comment that describes the rule.

config load-balance setting

Use this command to set a wide range of load balancing settings.

```
config load-balance setting
   set slbc-mgmt-intf {mgmt1 | mgmt2 | mgmt3}
   set max-miss-heartbeats <heartbeats>
   set max-miss-mgmt-heartbeats <heartbeats>
   set weighted-load-balance {disable | enable}
   set ipsec-load-balance {disable | enable}
   set gtp-load-balance {disable | enable}
   set dp-load-distribution-method {to-master | src-ip | dst-ip | src-dst-ip | src-ip-
       sport | dst-ip-dport | src-dst-ip-sport-dport}
      config workers
        edit 3
           set status enable
           set weight 5
        end
end
```

slbc-mgmt-intf {mgmt1 | mgmt2 | mgmt3}

Select the interface used for management connections. The name depends on the available management interfaces on the device you are managing. You can use this option to enable access to the FPCs directly using the special administration ports as described in Managing individual FPCs on page 759.

max-miss-heartbeats <heartbeats>

Set the number of missed heartbeats before a worker (an FPC or FPM module) is considered to have failed. If this many heartbeats are not received from a worker, this indicates that the worker is not able to process data traffic and no more traffic will be sent to this worker.

The time between heartbeats is 0.2 seconds. Range is 3 to 300. 3 means 0.6 seconds, 10 (the default) means 2 seconds, and 300 means 60 seconds.

max-miss-mgmt-heartbeats <heartbeats>

Set the number of missed management heartbeats before a worker (an FPC or FPM module) is considering to have failed. If this happens, there is a communication problem between a worker and other workers. This communication problem means the worker may not be able to synchronize configuration changes, sessions, the kernel routing table, the bridge table and so on with other workers. If a management heartbeat failure occurs, no traffic will be sent to the worker.

The time between management heartbeats is 1 second. Range is 3 to 300 seconds. The default is 20 seconds.

weighted-load-balance {disable | enable}

Enable weighted load balancing depending on the slot (or worker) weight. Use the `config workers` command to set the weight for each slot or worker.

gtp-load-balance {disable | enable}

Enable GTP load balancing. If GTP load balancing is enabled, Tunnel Endpoint Identifiers (TEIDs) are used to identify GTP sessions.

dp-load-distribution-method {to-master | round-robin | src-ip | dst-ip | src-dst-ip | src-ip-sport | dst-ip-dport | src-dst-ip-sport-dport}

Set the method used to distribute sessions among workers (FPCs or FPM modules). Usually you would only need to change the method if you had specific requirements or you found that the default method wasn't distributing sessions in the manner that you would prefer. The default is `src-dst-ip-sport-dport` which means sessions are identified by their source address and port and destination address and port.

`to-master` directs all session to the primary FPC. This method is for troubleshooting only and should not be used for normal operation. Directing all sessions to the primary FPC will have a negative impact on performance.

`src-ip` sessions are distributed across all FPCs according to their source IP address.

`dst-ip` sessions are statically distributed across all FPCs according to their destination IP address.

`src-dst-ip` sessions are distributed across all FPCs according to their source and destination IP addresses.

`src-ip-sport` sessions are distributed across all FPCs according to their source IP address and source port.

`dst-ip-dport` sessions are distributed across all FPCs according to their destination IP address and destination port.

`src-dst-ipsport-dport` sessions are distributed across all FPCs according to their source and destination IP address, source port, and destination port. This is the default load balance algorithm and represents true session-aware load balancing. All session information is taken into account when deciding where to send new sessions and where to send additional packets that are part of an already established session.

The `src-ip` and `dst-ip` load balancing methods use layer 3 information (IP addresses) to identify and load balance sessions. All of the other load balancing methods (except for `to-master`) use both layer 3 and layer 4 information (IP addresses and port numbers) to identify a TCP and UDP session. The layer 3 and layer 4 load balancing methods only use layer 3 information for other types of traffic (SCTP, ICMP, and ESP). If GTP load balancing is enabled, Tunnel Endpoint Identifiers (TEIDs) are used to identify GTP sessions.

config workers

Set the weight and enable or disable each worker (FPC or FPM module). Use the edit command to specify the slot the worker is installed in. You can enable or disable each worker and set each worker's weight.

The weight range is 1 to 10. 5 is average, 1 is -80% of average and 10 is +100% of average. The weights take effect if `weighted-loadbalance` is enabled.

```
config workers
   edit 3
      set status enable
      set weight 5
   end
```

Chapter 7 - FortiGate-7000

Fortigate-7000

This FortiOS Handbook chapter contains the following sections:

FortiGate-7000 overview provides a quick overview of FortiGate-7000 components.

Getting started with FortiGate-7000 describes how to get started with managing and configuring your FortiGate-7000 product.

Operating a FortiGate-7000 describes some FortiGate-7000 general operating procedures.

IPsec VPN describes FortiGate-7000-specific IPsec VPN considerations.

High availability describes how to set up FortiGate-7000 high availability.

FortiGate-7000 v5.4.9 special features and limitations describes some special limitations of FortiGate-7000 running FortiOS v5.4.9.

FortiGate-7000 v5.4.5 special features and limitations describes some special limitations of FortiGate-7000 running FortiOS v5.4.5.

FortiGate-7000 v5.4.3 special features and limitations describes some special limitations of FortiGate-7000 running FortiOS v5.4.3.

FortiGate-7000 Load balancing commands describes FortiGate-7000 load balancing CLI commands.

What's new in for FortiGate-7000 v5.4.9 build 8110

Version 5.4.9 enhancements mainly consisted of adding FortiOS 5.4.9 to the FortiGate-7000 platform. This release also includes bug fixes and improvements and one additional new feature.

Brief logging mode

Brief logging mode, a carrier grade NAT (CGN) feature, removes some fields from log messages to reduce log message size. Smaller log messages reduces disk space usage and also reduces remote logging network bandwidth usage. Brief logging mode is useful if your FortiGate-7000 system generates a large amount of log messages.

Use the following command to enable brief logging mode for all logging:

```
config log setting
   set brief-traffic-format enable
end
```

What's new in for FortiGate-7000 v5.4.5 build 8047

The following new features have been added to FortiGate-7000 v5.4.5.

The maximum value for user groups has been increased to 5,000 (460857)

On a FortiGate-7000, you can now configure up to 5,000 user groups.

Log field extension policy-name and meta-field (461783 455441)

An option to include the policy name field has been added to traffic logs (log-policy-name). An option to add a meta-field tag to all logs has also been added (custom-field and custom-log-fields; see below). This meta-field could be used to identify the FortiGate sending the logs, for example:

```
config log setting
   set log-policy-name enable
end
config log custom-field
   edit "cust-field"
      set name "MyFortiGate"
      set value "111"
   next
   end
      config log setting
      set custom-log-fields "cust-field"
   end
```

M1 and M2 interfaces can use different VLANs for heartbeat traffic (408386)

The M1 and M2 interfaces can be configured to use different VLANs for HA heartbeat traffic. Normally you would separate the M1 and M2 traffic. In that case you don't have to change their VLAN IDs. But if the M1 and M2 interfaces are connected to the same switch and you can't separate their traffic, or if you can't use the default VLAN IDs you can set a different VLAN ID for each interface.

Use the following command set the M1 and M2 interfaces to use different VLANs:

```
config system ha
   set hbdev M1/M2
   set hbdev-vlan-id 991
   set hbdev-second-vlan-id 992
end
```

For this configuration to work the `hbdev-vlan-id` has to be changed. You cannot use the default value of 999.

GTP load balancing

GTP load balancing is supported for FortiGate-7000 configurations licensed for FortiOS Carrier. You can use the following command to enable GTP load balancing. This command is only available after you have licensed the FortiGate-7000 for FortiOS Carrier.

```
config load-balance setting
   set gtp-load-balance enable
end
```

FSSO user authentication synchronization

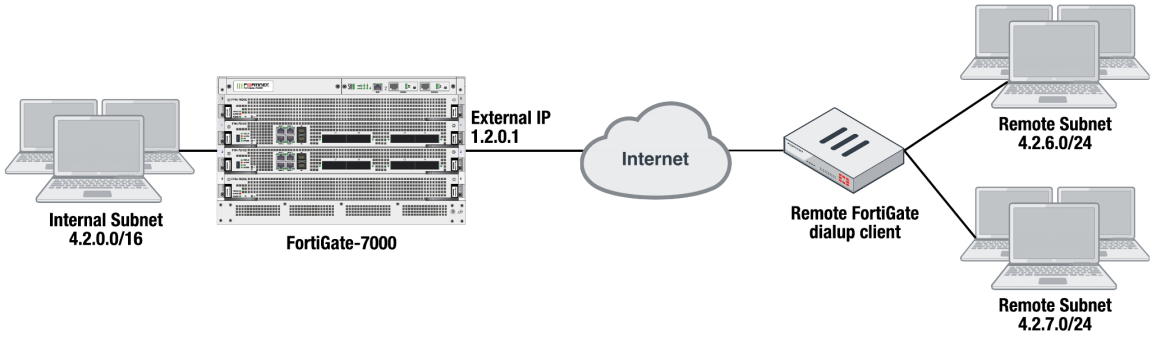
FSSO user authentication is synchronized to all FPMs. Users authenticated through FSSO no longer have to re-authenticate when load balancing distributes their session to a different FPM.

HA link failure threshold changes (422264)

The link failure threshold is now determined based on the all FIMs in a chassis. This means that the chassis with the fewest active links will become the backup chassis.

FortiGate-7000s running FortiOS v5.4.5 can be configured as dialup IPsec VPN servers

The following shows how to setup a dialup IPsec VPN configuration where the FortiGate-7000 running v5.4.5 acts as a dialup IPsec VPN server.



Configure the phase1, set type to dynamic.

```
config vpn ipsec phase1-interface
   edit dialup-server
      set type dynamic
      set interface "v0020"
      set peertype any
      set psksecret < password>
   end
```

Configure the phase 2, to support dialup IPsec VPN, set the destination subnet to 0.0.0.0 0.0.0.0.

```
config vpn ipsec phase2-interface
   edit dialup-server
      set phase1name dialup-server
      set src-subnet 4.2.0.0 255.255.0.0
      set dst-subnet 0.0.0.0 0.0.0.0
   end
```

To configure the remote FortiGate as a dialup IPsec VPN client

The dialup IPsec VPN client should advertise its local subnet(s) using the phase 2 src-subnet option.

If there are multiple local subnets create a phase 2 for each one. Each phase 2 only advertises one local subnet to the dialup IPsec VPN server. If more than one local subnet is added to the phase 2, only the first one is advertised to the server.

Dialup client configuration:

```
config vpn ipsec phase1-interface
   edit "to-fgt7k"
      set interface "v0020"
```

```
      set peertype any
      set remote-gw 1.2.0.1
      set psksecret <password>
   end
config vpn ipsec phase2-interface
   edit "to-fgt7k"
      set phase1name "to-fgt7k"
      set src-subnet 4.2.6.0 255.255.255.0
      set dst-subnet 4.2.0.0 255.255.0.0
   next
   edit "to-fgt7k-2"
      set phase1name "to-fgt7k"
      set src-subnet 4.2.7.0 255.255.255.0
      set dst-subnet 4.2.0.0 255.255.0.0
   end
```

FortiGate-7000 overview

A FortiGate-7000 product consists of a FortiGate-7000 series chassis (for example, the FortiGate-7040E) with FortiGate-7000 modules installed in the chassis slots. A FortiGate-7040E chassis comes with two interface modules (FIM) to be installed in slots 1 and 2 to provide network connections and session-aware load balancing to two processor modules (FPM) to be installed in slots 3 and 4.

FortiGate-7000 products are sold and licensed as packages that include the chassis as well as the modules to be included in the chassis. When you receive your FortiGate-7000 series product the chassis has to be installed in a rack and the modules installed in the chassis. Interface modules always go in slots 1 and 2 and processor modules in slots 3 and up.

If your FortiGate-7000 product includes two different interfaces modules, for optimal configuration you should install the module with the lower model number in slot 1 and the module with the higher model number in slot 2. For example, if your chassis includes a FIM-7901E and a FIM-7904E, install the FIM-7901E in chassis slot 1 and the FIM-7904E in chassis slot 2. This applies to any combination of two different interface modules.

As an administrator, when you browse to the FortiGate-7000 management IP address you log into the interface module in slot 1 (the primary or master interface module or FIM) to view the status of the FortiGate-7000 and make configuration changes. The FortiOS firmware running on each module has the same configuration and when you make configuration changes to the primary interface module, the configuration changes are synchronized to all modules.

The same FortiOS firmware build runs on each module in the chassis. You can upgrade FortiGate-7000 firmware by logging into the primary interface module and performing a firmware upgrade as you would for any FortiGate. During the upgrade process the firmware of all of the modules in the chassis upgrades in one step. Firmware upgrades should be done during a quiet time because traffic will briefly be interrupted during the upgrade process.

Licenses, device registration, and support

A FortiGate-7000 product is made up of a FortiGate-7000 series chassis, one or two FIM interface modules and two to four FPM processor modules. The entire package is licensed and configured as a single product under the FortiGate-7000 chassis serial number. When you receive a new FortiGate-7000 product you register it on https://support.fortinet.com using the chassis serial number. Use the chassis serial number when requesting support from Fortinet for the product.

All Fortinet licensing, including FortiCare Support, IPS, AntiVirus, Web Filtering, Mobile Malware, FortiClient, FortiCloud, and additional virtual domains (VDOM) is for the entire FortiGate-7000 product and not for individual components.

If an individual component, such as a single interface or processor fails you can RMA and replace just that component.

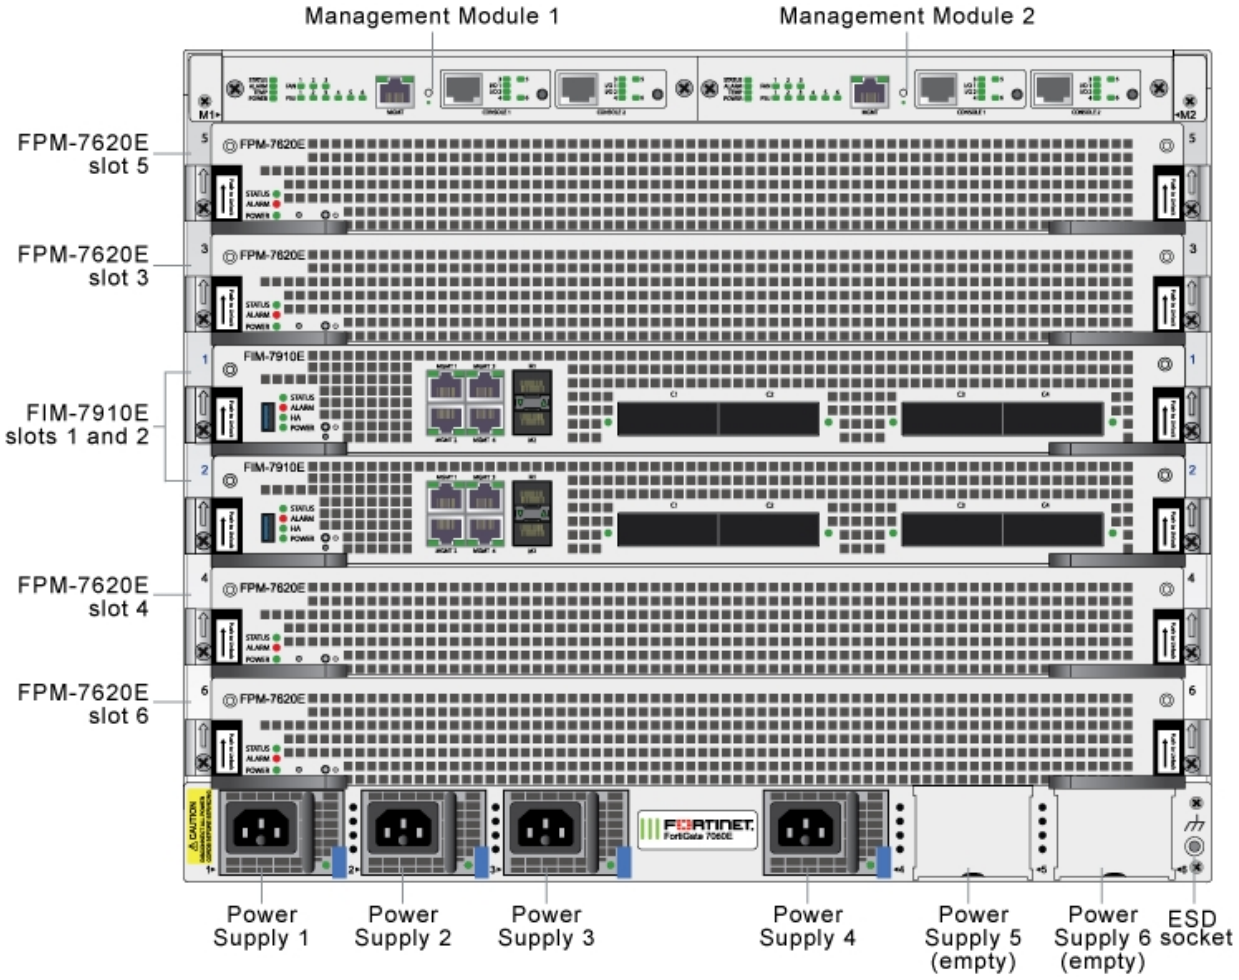
FortiGate-7060E

The FortiGate-7060E is a 8U 19-inch rackmount 6-slot chassis with a 80Gbps fabric and 1Gbps base backplane designed by Fortinet. The fabric backplane provides network data communication and the base backplane provides management and synch communication among the chassis slots.

FortiGate-7060E front panel

The chassis is managed by two redundant management modules. Each module includes an Ethernet connection as well as two switchable console ports that provide console connections to the modules in the chassis slots. The active management module controls chassis cooling and power management and provides an interface for managing the modules installed in the chassis.

FortiGate-7060E front panel, (example module configuration)

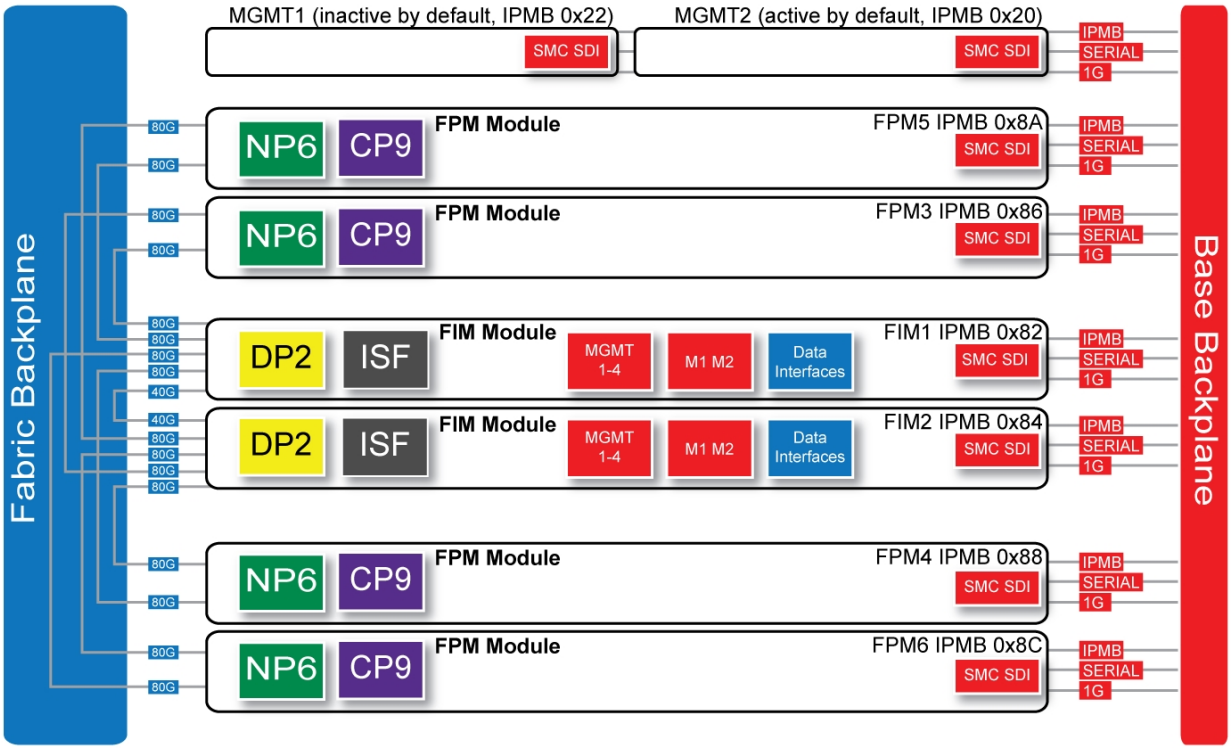


Power is provided to the chassis using four hot swappable 3+1 redundant 100-240 VAC, 50-60 Hz power supply units (PSUs). You can also optionally add up to six PSUs to provide 3+3 redundancy. The FortiGate-7060E can also be equipped with DC PSUs allowing you to connect the chassis to -48V DC power

The standard configuration of the FortiGate-7060E includes two FIM (interface) modules in chassis slots 1 and 2 and up to four FPM (processing) modules in chassis slots 3 to 6.

FortiGate-7060E schematic

The FortiGate-7060E chassis schematic below shows the communication channels between chassis components including the management modules (MGMT), the FIMs (called FIM1 and FIM2) and the FPMs (FPM3, FPM4, FPM5, and FPM6).



By default, MGMT2 is the active management module and MGMT1 is inactive. The active management module always has the Intelligent Platform Management Bus (IPMB) address 0x20 and the inactive management module always has the IPMB address 0x22.

The active management module communicates with all modules in the chassis over the base backplane. Each module, including the management modules has a Shelf Management Controller (SMC). These SMCs support IPMB communication between the active management module and the FIM and FPMs for storing and sharing sensor data that the management module uses to control chassis cooling and power distribution. The base backplane also supports serial communications to allow console access from the management module to all modules, and 1Gbps Ethernet communication for management and heartbeat communication between modules.

FIM1 and FIM2 (IPMB addresses 0x82 and 0x84) are the FIMs in slots 1 and 2. The interfaces of these modules connect the chassis to data networks and can be used for Ethernet management access to chassis components. The FIMs include DP2 processors that distribute sessions over the Integrated Switch Fabric (ISF) to the NP6 processors in the FPMs. Data sessions are communicated to the FPMs over the 80Gbps chassis fabric backplane.

FPM03, FPM04, FPM05, and FPM06 (IPMB addresses 0x86, 0x88, 0x8A, and 0x8C) are the FPM processor modules in slots 3 to 6. These worker modules process sessions distributed to them by the FIMs. FPMs include NP6 processors to offload sessions from the FPM CPU and CP9 processors that accelerate content processing.

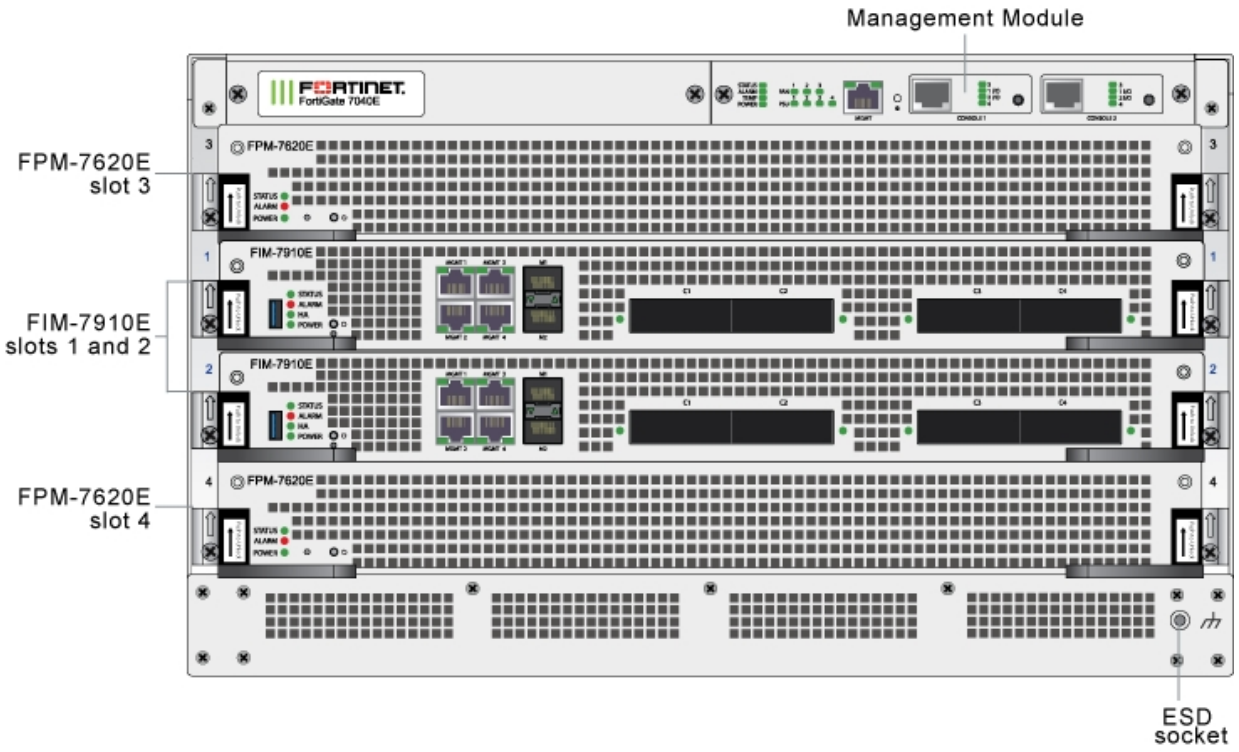
FortiGate-7040E

The FortiGate-7040E is a 6U 19-inch rackmount 4-slot chassis with a 80Gbps fabric and 1Gbps base backplane designed by Fortinet. The fabric backplane provides network data communication and the base backplane provides management and synch communication among the chassis slots.

FortiGate-7040E front panel

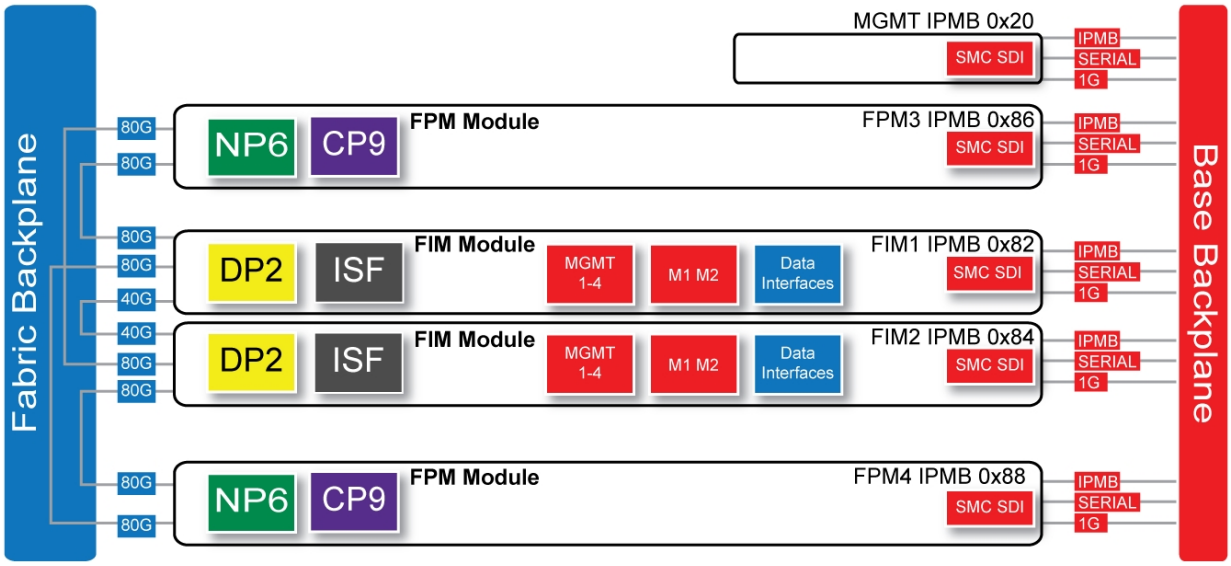
The FortiGate-7040E chassis is managed by a single management module that includes an Ethernet connection as well as two switchable console ports that provide console connections to the modules in the chassis slots. The management module controls chassis cooling and power management and provides an interface for managing the modules installed in the chassis. The standard configuration of the FortiGate-7040E includes two FIM (interface) modules in chassis slots 1 and 2 and two FPM (processing) modules in chassis slots 3 and 4.

FortiGate-7040E front panel



FortiGate-7040E schematic

The FortiGate-7040E chassis schematic below shows the communication channels between chassis components including the management module (MGMT), the FIMs (called FIM1 and FIM2) and the FPMs (FPM3 and FPM4).



The management module (MGMT, with Intelligent Platform Management Bus (IPMB) address 0x20) communicates with all modules in the chassis over the base backplane. Each module, including the management module, includes a Shelf Management Controller (SMC). These SMCs support IPMB communication between the management module and the FIM and FPMs for storing and sharing sensor data that the management module uses to control chassis cooling and power distribution. The base backplane also supports serial communications to allow console access from the management module to all modules, and 1Gbps Ethernet communication for management and heartbeat communication between modules.

FIM1 and FIM2 (IPMB addresses 0x82 and 0x84) are the FIMs in slots 1 and 2. The interfaces of these modules connect the chassis to data networks and can be used for Ethernet management access to chassis components. The FIMs include DP2 processors that distribute sessions over the Integrated Switch Fabric (ISF) to the NP6 processors in the FPMs. Data sessions are communicated to the FPMs over the 80Gbps chassis fabric backplane.

FPM3 and FPM4 (IPMB addresses 0x86 and 0x88) are the FPM processor modules in slots 3 and 4. These worker modules process sessions distributed to them by the FIMs. FPMs include NP6 processors to offload sessions from the FPM CPU and CP9 processors that accelerate content processing.

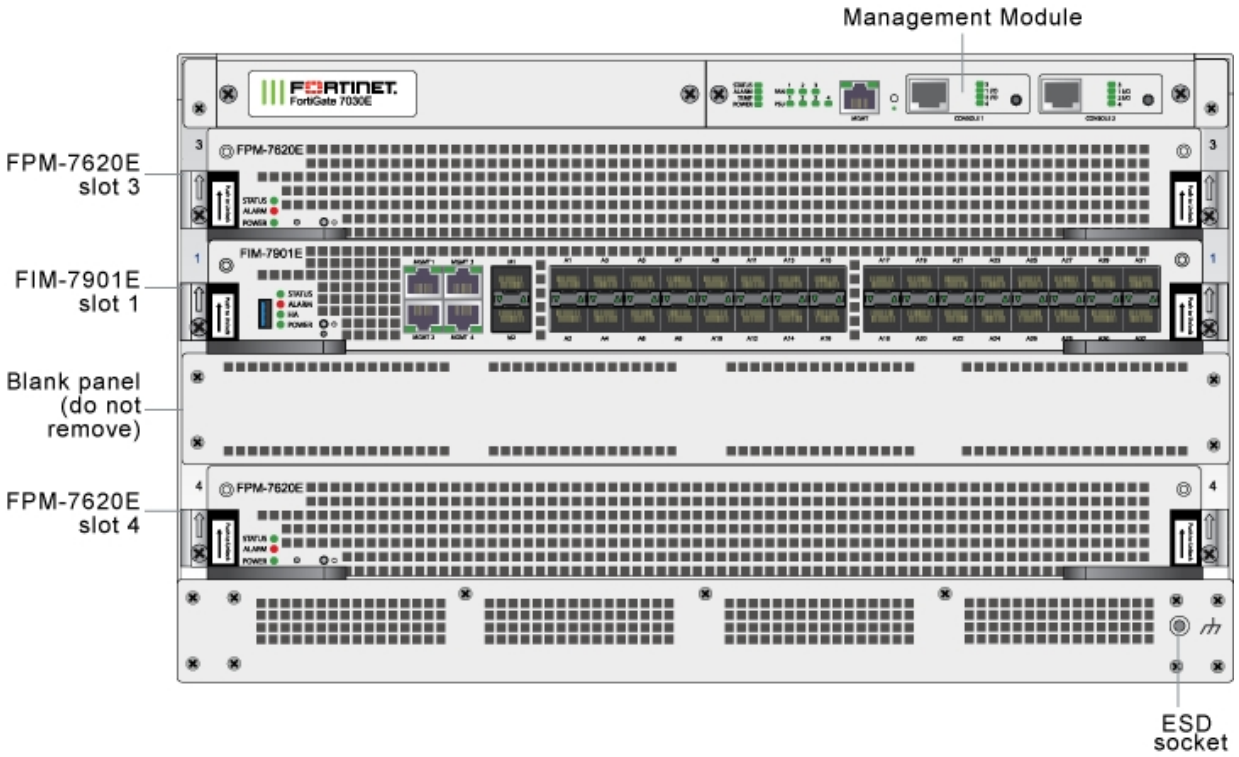
FortiGate-7030E

The FortiGate-7030E is a 6U 19-inch rackmount 3-slot chassis with a 80Gbps fabric and 1Gbps base backplane designed by Fortinet. The fabric backplane provides network data communication and the base backplane provides management and synch communication among the chassis slots.

FortiGate-7030E front panel

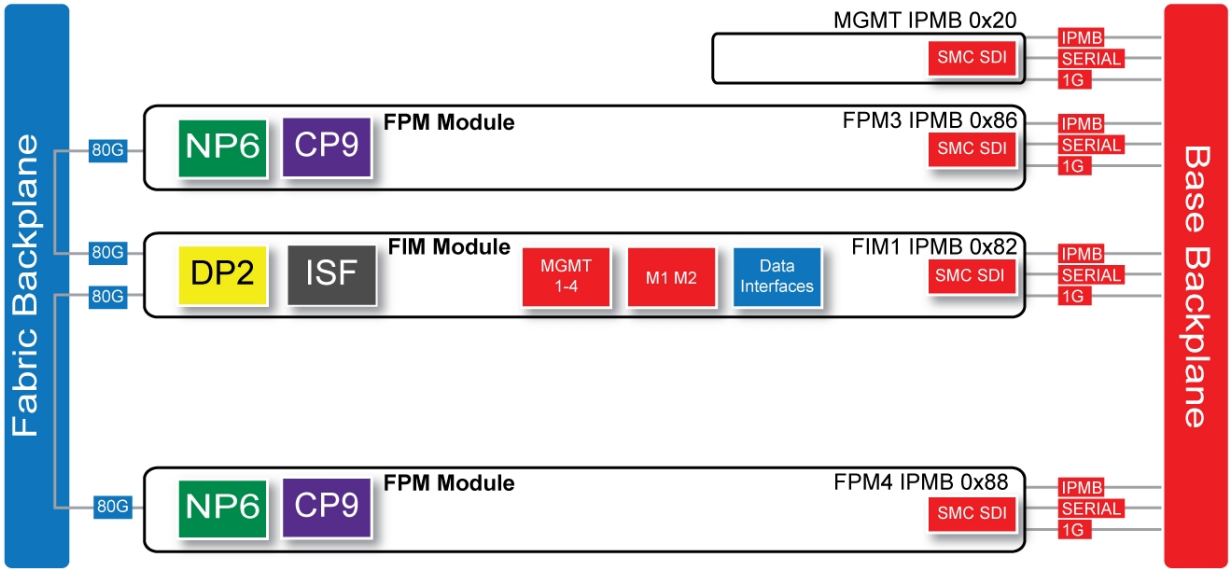
The FortiGate-7030E chassis is managed by a single management module that includes an Ethernet connection as well as two switchable console ports that provide console connections to the modules in the chassis slots. The management module controls chassis cooling and power management and provides an interface for managing the modules installed in the chassis. The standard configuration of the FortiGate-7030E includes one FIM (interface) module in chassis slot 1 and two FPM (processing) modules in chassis slots 3 and 4. The front panel also includes a sealed blank panel. Breaking the seal or removing the panel voids your FortiGate-7030E warranty.

FortiGate-7030E front panel (example module configuration)



FortiGate-7030E schematic

The FortiGate-7030E chassis schematic below shows the communication channels between chassis components including the management module (MGMT), the FIM (called FIM1) and the FPMs (FPM3 and FPM4).



The management module (MGMT, with Intelligent Platform Management Bus (IPMB) address 0x20) communicates with all modules in the chassis over the base backplane. Each module, including the management module includes a Shelf Management Controller (SMC). These SMCs support IPMB communication between the

management module and the FIM and FPMs for storing and sharing sensor data that the management module uses to control chassis cooling and power distribution. The base backplane also supports serial communications to allow console access from the management module to all modules, and 1Gbps Ethernet communication for management and heartbeat communication between modules.

FIM1 (IPMB address 0x82) is the FIM in slot 1. The interfaces of this module connect the chassis to data networks and can be used for Ethernet management access to chassis components. The FIM includes DP2 processors that distribute sessions over the Integrated Switch Fabric (ISF) to the NP6 processors in the FPMs. Data sessions are communicated to the FPMs over the 80Gbps chassis fabric backplane.

FPM3 and FPM4 (IPMB addresses 0x86 and 0x88) are the FPM processor modules in slots 3 and 4. These worker modules process sessions distributed to them by the FIM. FPMs include NP6 processors to offload sessions from the FPM CPU and CP9 processors that accelerate content processing.

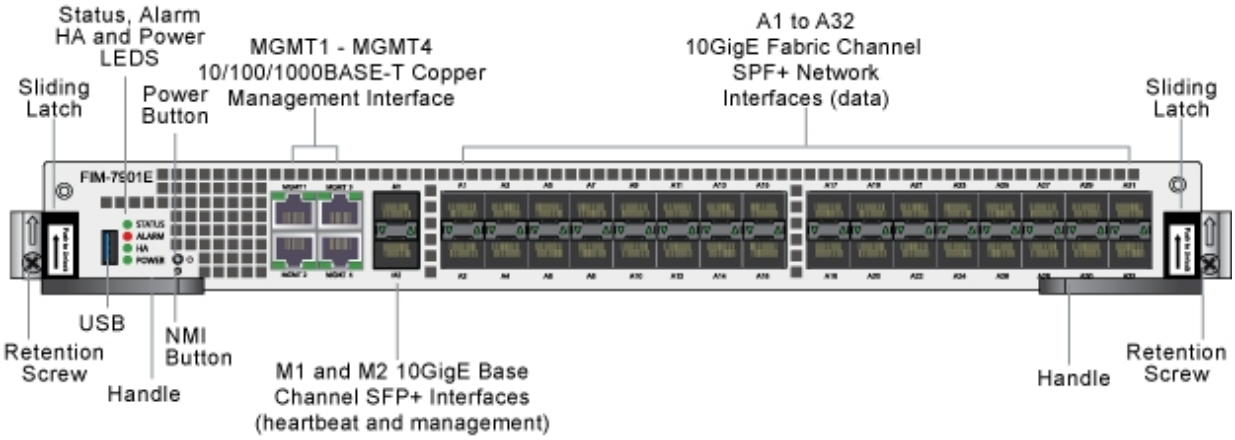
FIM-7901E interface module

The FIM-7901E interface module is a hot swappable module that provides data, management and session sync/heartbeat interfaces, base backplane switching and fabric backplane session-aware load balancing for a FortiGate-7000 chassis. The FIM-7901E includes an integrated switch fabric and DP2 processors to load balance millions of data sessions over the chassis fabric backplane to FPM processor modules.

The FIM-7901E can be installed in any FortiGate-7000 series chassis in hub/switch slots 1 and 2. The FIM-7901E provides thirty-two 10GigE small form-factor pluggable plus (SPF+) interfaces for a FortiGate-7000 chassis.

You can also install FIM-7901Es in a second chassis and operate the chassis in HA mode with another set of processor modules to provide chassis failover protection.

FIM-7901E front panel



The FIM-7901E includes the following hardware features:

- Thirty-two front panel 10GigE SFP+ fabric channel interfaces (A1 to A32). These interfaces are connected to 10Gbps networks to distribute sessions to the FPM processor modules installed in chassis slots 3 and up. These interfaces can also be configured to operate as Gigabit Ethernet interfaces using SFP transceivers. These interfaces also support creating link aggregation groups (LAGs) that can include interfaces from both FIM-7901Es.
- Two front panel 10GigE SFP+ interfaces (M1 and M2) that connect to the base backplane channel. These interfaces are used for heartbeat, session sync, and management communication between FIM-7901Es in different chassis. These interfaces can also be configured to operate as Gigabit Ethernet interfaces using SFP transceivers, but should not normally be changed. If you use switches to connect these interfaces, the switch ports should be

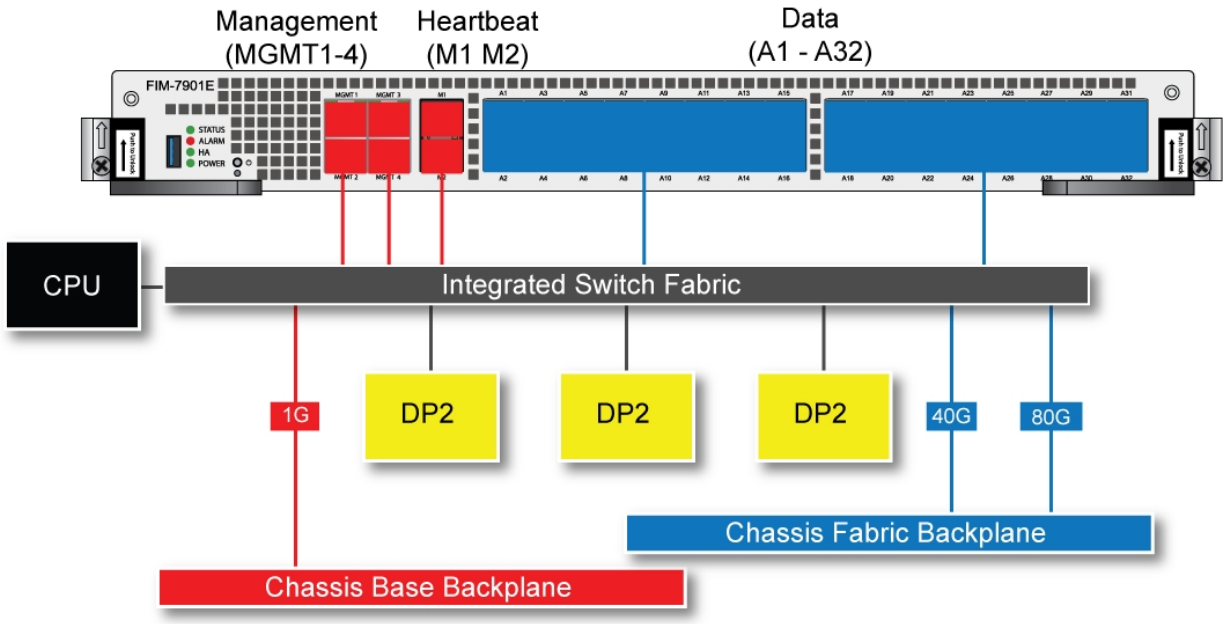
able to accept packets with a maximum frame size of at least 1526. The M1 and M2 interfaces need to be on different broadcast domains. If M1 and M2 are connected to the same switch, Q-in-Q must be enabled on the switch.

- Four 10/100/1000BASE-T out of band management Ethernet interfaces (MGMT1 to MGMT4).
- One 80Gbps fabric backplane channel for traffic distribution with each FPM installed in the same chassis as the FIM-7901E.
- One 1Gbps base backplane channel for base backplane with each FPM installed in the same chassis as the FIM-7901E.
- One 40Gbps fabric backplane channel for fabric backplane communication with the other FIM-7901E in the chassis.
- One 1Gbps base backplane channel for base backplane communication with the other FIM-7901E in the chassis.
- On-board DP2 processors and an integrated switch fabric to provide high-capacity session-aware load balancing.
- One front panel USB port.
- Power button.
- NMI switch (for troubleshooting as recommended by Fortinet Support).
- Mounting hardware.
- LED status indicators.

FIM-7901E schematic

The FIM-7901E includes an integrated switch fabric (ISF) that connects the FIM front panel interfaces to the DP2 session-aware load balancers and to the chassis fabric and base backplanes. The ISF also allows the DP2 processors to distribute sessions among all NP6 processors on the FortiGate Processor Modules (FPM) in the FortiGate-7000 chassis.

FIM-7901E schematic



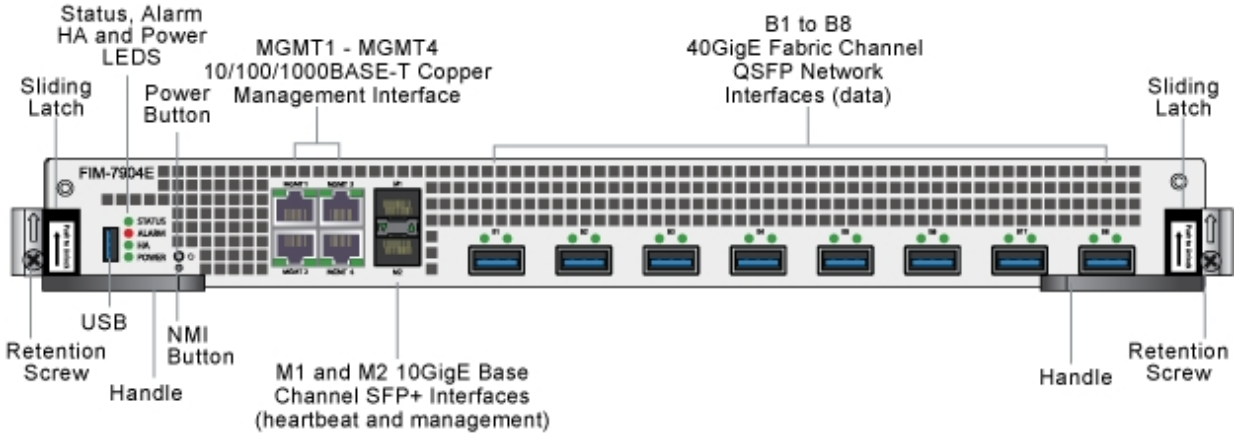
FIM-7904E interface module

The FIM-7904E interface module is a hot swappable module that provides data, management and session sync/heartbeat interfaces, base backplane switching and fabric backplane session-aware load balancing for a FortiGate-7000 series chassis. The FIM-7904E includes an integrated switch fabric and DP2 processors to load balance millions of data sessions over the chassis fabric backplane to FPM processor modules.

The FIM-7904E can be installed in any FortiGate-7000 series chassis in hub/switch slots 1 and 2. The FIM-7904E provides four Quad Small Form-factor Pluggable plus (QSFP+) interfaces for a FortiGate-7000 chassis. Using a 40GBASE-SR10 multimode QSFP+ transceiver, each QSFP+ interface can also be split into four 10GBASE-SR interfaces.

You can also install FIM-7904Es in a second chassis and operate the chassis in HA mode with another set of processor modules to provide chassis failover protection.

FIM-7904E front panel



The FIM-7904E includes the following hardware features:

- Eight front panel 40GigE QSFP+ fabric channel interfaces (B1 to B8). These interfaces are connected to 40Gbps networks to distribute sessions to the FPM processor modules installed in chassis slots 3 and up. Using 40GBASE-SR10 multimode QSFP+ transceivers, each QSFP+ interface can also be split into four 10GBASE-SR interfaces. These interfaces also support creating link aggregation groups (LAGs) that can include interfaces from both FIM-7904Es.
- Two front panel 10GigE SFP+ interfaces (M1 and M2) that connect to the base backplane channel. These interfaces are used for heartbeat, session sync, and management communication between FIM-7904Es in different chassis. These interfaces can also be configured to operate as Gigabit Ethernet interfaces using SFP transceivers, but should not normally be changed. If you use switches to connect these interfaces, the switch ports should be able to accept packets with a maximum frame size of at least 1526. The M1 and M2 interfaces need to be on different broadcast domains. If M1 and M2 are connected to the same switch, Q-in-Q must be enabled on the switch.
- Four 10/100/10000BASE-T out of band management Ethernet interfaces (MGMT1 to MGMT4).
- One 80Gbps fabric backplane channel for traffic distribution with each FPM installed in the same chassis as the FIM-7904E.
- One 1Gbps base backplane channel for base backplane with each FPM installed in the same chassis as the FIM-7904E.
- One 40Gbps fabric backplane channel for fabric backplane communication with the other FIM-7904E in the chassis.

- One 1Gbps base backplane channel for base backplane communication with the other FIM-7904E in the chassis.
- On-board DP2 processors and an integrated switch fabric to provide high-capacity session-aware load balancing.
- One front panel USB port.
- Power button.
- NMI switch (for troubleshooting as recommended by Fortinet Support).
- Mounting hardware.
- LED status indicators.

Splitting the FIM-7904E B1 to B8 interfaces

Each 40GE interface (B1 to B8) on the FIM-7904Es in slot 1 and slot 2 of a FortiGate-7000 system can be split into 4x10GBE interfaces. You split these interfaces after the FIM-7904Es are installed in your FortiGate-7000 system and the system us up and running. You can split the interfaces of the FIM-7904Es in slot 1 and slot 2 at the same time by entering a single CLI command. Splitting the interfaces requires a system reboot so Fortinet recommends that you split multiple interfaces at the same time according to your requirements to avoid traffic disruption.

For example, to split the B1 interface of the FIM-7904E in slot 1 (this interface is named 1-B1) and the B1 and B4 interfaces of the FIM-7904E in slot 2 (these interfaces are named 2-B1 and 2-B4) connect to the CLI of your FortiGate-7000 system using the management IP and enter the following command:

```
config system global
   set split-port 1-B1 2-B1 2-B4
end
```

After you enter the command, the FortiGate-7000 reboots and when it comes up:

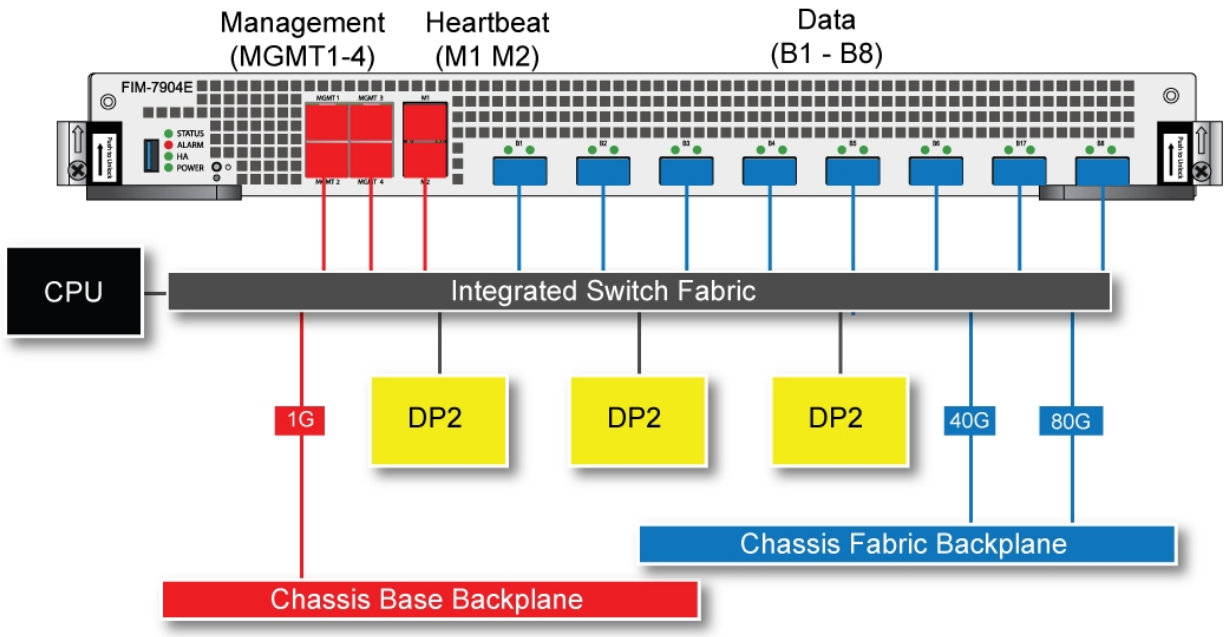
- The 1-B1 interface will no longer be available. Instead the 1-B1/1, 1-B1/2, 1-B1/3, and 1-B1/4 interfaces will be available.
- The 2-B1 interface will no longer be available. Instead the 2-B1/1, 2-B1/2, 2-B1/3, and 2-B1/4 interfaces will be available.
- The 2-B4 interface will no longer be available. Instead the 2-B4/1, 2-B4/2, 2-B4/3, and 2-B4/4 interfaces will be available.

You can now connect breakout cables to these interfaces and configure traffic between them just like any other FortiGate interface.

FIM-7904E hardware schematic

The FIM-7904E includes an integrated switch fabric (ISF) that connects the front panel interfaces to the DP2 session-aware load balancers and to the chassis backplanes. The ISF also allows the DP2 processors to distribute sessions among all NP6 processors on the FortiGate Processor Modules (FPM) in the FortiGate-7000 chassis.

FIM-7904E hardware architecture

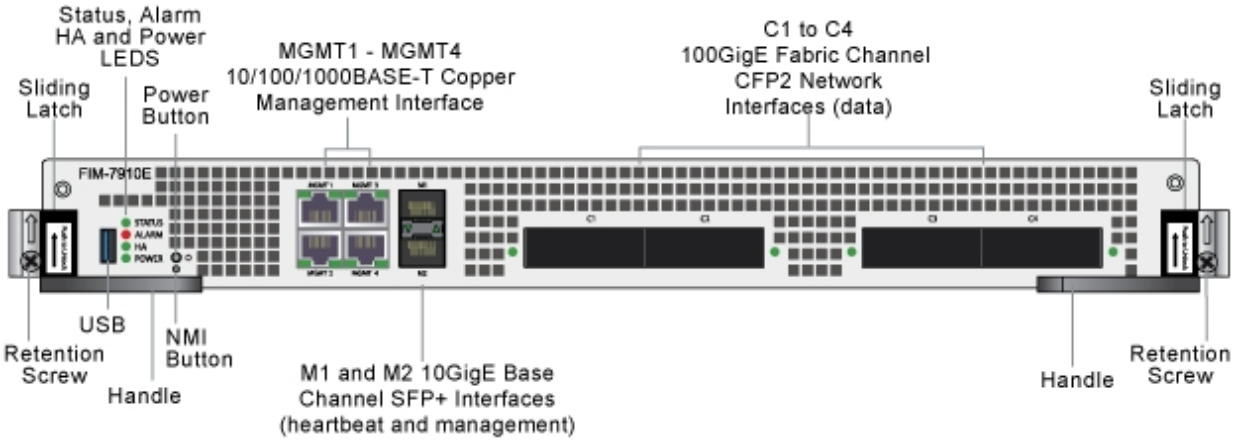


FIM-7910E interface module

The FIM-7910E interface module is a hot swappable module that provides data, management and session sync/heartbeat interfaces, base backplane switching and fabric backplane session-aware load balancing for a FortiGate-7000 series chassis. The FIM-7910E includes an integrated switch fabric and DP2 processors to load balance millions of data sessions over the chassis fabric backplane to FPM processor modules.

The FIM-7910E can be installed in any FortiGate-7000 series chassis in hub/switch slots 1 and 2. The FIM-7910E provides four C form-factor pluggable 2 (CFP2) interfaces for a FortiGate-7000 chassis. Using a 100GBASE-SR10 multimode CFP2 transceiver, each CFP2 interface can also be split into ten 10GBASE-SR interfaces.

FIM-7910E front panel



The FIM-7910E includes the following hardware features:

- Four front panel 100GigE CFP2 fabric channel interfaces (C1 to C4). These interfaces are connected to 100Gbps networks to distribute sessions to the FPM processor modules installed in chassis slots 3 and up. Using 100GBASE-SR10 multimode CFP2 transceivers, each CFP2 interface can also be split into ten 10GBASE-SR interfaces. These interfaces also support creating link aggregation groups (LAGs) that can include interfaces from both FIM-7910Es.
- Two front panel 10GigE SFP+ interfaces (M1 and M2) that connect to the base backplane channel. These interfaces are used for heartbeat, session sync, and management communication between FIM-7910Es in different chassis. These interfaces can also be configured to operate as Gigabit Ethernet interfaces using SFP transceivers, but should not normally be changed. If you use switches to connect these interfaces, the switch ports should be able to accept packets with a maximum frame size of at least 1526. The M1 and M2 interfaces need to be on different broadcast domains. If M1 and M2 are connected to the same switch, Q-in-Q must be enabled on the switch.
- Four 10/100/1000BASE-T out of band management Ethernet interfaces (MGMT1 to MGMT4).
- One 80Gbps fabric backplane channel for traffic distribution with each FPM installed in the same chassis as the FIM-7910E.
- One 1Gbps base backplane channel for base backplane with each FPM installed in the same chassis as the FIM-7910E.
- One 40Gbps fabric backplane channel for fabric backplane communication with the other FIM-7910E in the chassis.
- One 1Gbps base backplane channel for base backplane communication with the other FIM-7910E in the chassis.
- On-board DP2 processors and an integrated switch fabric to provide high-capacity session-aware load balancing.
- One front panel USB port.
- Power button.
- NMI switch (for troubleshooting as recommended by Fortinet Support).
- Mounting hardware.
- LED status indicators.

Splitting the FIM-7910E C1 to C4 interfaces

Each 100GE interface (C1 to C4) on the FIM-7910Es in slot 1 and slot 2 of a FortiGate-7000 system can be split into 10 x 10GBE interfaces. You split these interfaces after the FIM-7910Es are installed in your FortiGate-7000 system and the system us up and running. You can split the interfaces of the FIM-7910Es in slot 1 and slot 2 at the same time by entering a single CLI command. Splitting the interfaces requires a system reboot so Fortinet recommends that you split multiple interfaces at the same time according to your requirements to avoid traffic disruption.

For example, to split the C1 interface of the FIM-7910E in slot 1 (this interface is named 1-C1) and the C1 and C4 interfaces of the FIM-7910E in slot 2 (these interfaces are named 2-C1 and 2-C4) connect to the CLI of your FortiGate-7000 system using the management IP and enter the following command:

```
config system global
   set split-port 1-C1 2-C1 2-C4
end
```

After you enter the command, the FortiGate-7000 reboots and when it comes up:

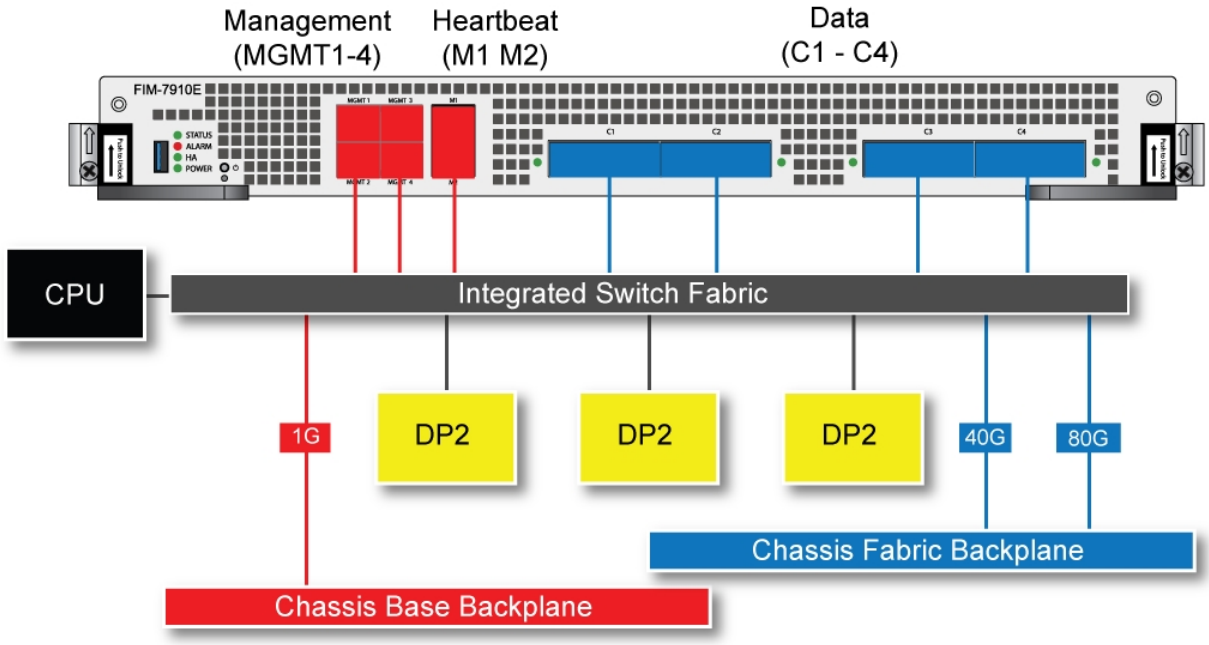
- The 1-C1 interface will no longer be available. Instead the 1-C1/1, 1-C1/2, ..., and 1-C1/10 interfaces will be available.
- The 2-C1 interface will no longer be available. Instead the 2-C1/1, 2-C1/2, ..., and 2-C1/10 interfaces will be available.
- The 2-C4 interface will no longer be available. Instead the 2-C4/1, 2-C4/2, ..., and 2-C4/10 interfaces will be available.

You can now connect breakout cables to these interfaces and configure traffic between them just like any other FortiGate interface.

FIM-7910E hardware schematic

The FIM-7910E includes an integrated switch fabric (ISF) that connects the front panel interfaces to the DP2 session-aware load balancers and to the chassis backplanes. The ISF also allows the DP2 processors to distribute sessions among all NP6 processors on the FortiGate Processor Modules (FPM) in the FortiGate-7000chassis.

FIM-7910E hardware schematic



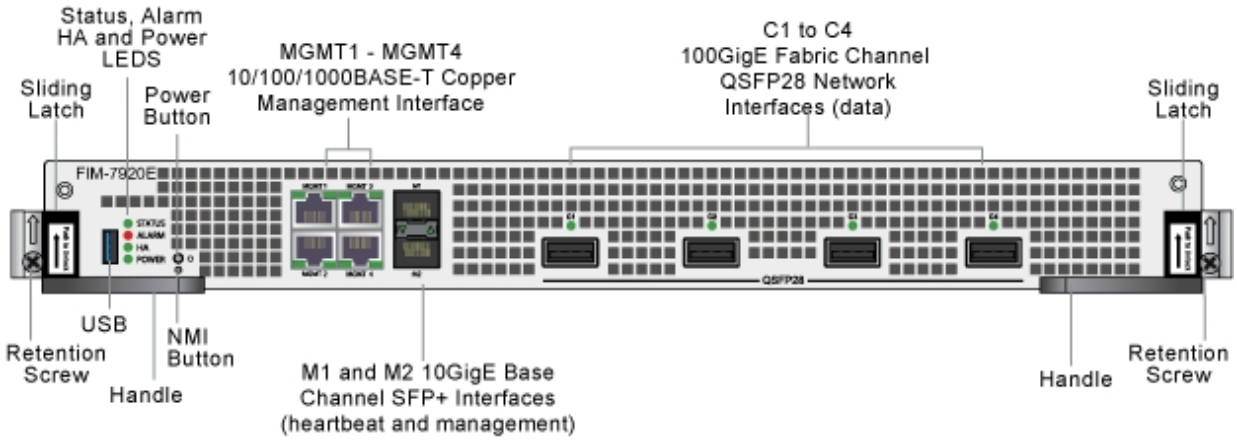
FIM-7920E interface module

The FIM-7920E interface module is a hot swappable module that provides data, management and session sync/heartbeat interfaces, base backplane switching and fabric backplane session-aware load balancing for a FortiGate-7000 series chassis. The FIM-7920E includes an integrated switch fabric and DP2 processors to load balance millions of data sessions over the chassis fabric backplane to FPM processor modules.

The FIM-7920E can be installed in any FortiGate-7000 series chassis in hub/switch slots 1 or 2. The FIM-7920E provides four Quad Small Form-factor Pluggable 28 (QSFP28) 100GigE interfaces for a FortiGate-7000 chassis. Using a 100GBASE-SR4 QSFP28 or 40GBASE-SR4 QSFP+ transceiver, each QSFP28 interface can also be split into four 10GBASE-SR interfaces.

You can also install FIM-7920Es in a second chassis and operate the chassis in HA mode with another set of processor modules to provide chassis failover protection.

FIM-7920E front panel



The FIM-7920E includes the following hardware features:

- Four front panel 100GigE QSFP28 fabric channel interfaces (C1 to C4). These interfaces are connected to 100Gbps networks to distribute sessions to the FPM processor modules installed in chassis slots 3 and up. Using a 100GBASE-SR4 QSFP28 or 40GBASE-SR4 QSFP+ transceiver, each QSFP28 interface can also be split into four 10GBASE-SR interfaces. These interfaces also support creating link aggregation groups (LAGs) that can include interfaces from both FIM-7920Es.
- Two front panel 10GigE SFP+ interfaces (M1 and M2) that connect to the base backplane channel. These interfaces are used for heartbeat, session sync, and management communication between FIM-7920Es in different chassis. These interfaces can also be configured to operate as Gigabit Ethernet interfaces using SFP transceivers, but should not normally be changed. If you use switches to connect these interfaces, the switch ports should be able to accept packets with a maximum frame size of at least 1526. The M1 and M2 interfaces need to be on different broadcast domains. If M1 and M2 are connected to the same switch, Q-in-Q must be enabled on the switch.
- Four 10/100/1000BASE-T out of band management Ethernet interfaces (MGMT1 to MGMT4).
- One 80Gbps fabric backplane channel for traffic distribution with each FPM installed in the same chassis as the FIM-7920E.
- One 1Gbps base backplane channel for base backplane with each FPM installed in the same chassis as the FIM-7920E.
- One 40Gbps fabric backplane channel for fabric backplane communication with the other FIM-7920E in the chassis.
- One 1Gbps base backplane channel for base backplane communication with the other FIM-7920E in the chassis.
- On-board DP2 processors and an integrated switch fabric to provide high-capacity session-aware load balancing.
- One front panel USB port.
- Power button.
- NMI switch (for troubleshooting as recommended by Fortinet Support).
- Mounting hardware.
- LED status indicators.

Changing the interface type and splitting the FIM-7920E C1 to C4 interfaces

By default, the FIM-7920E C1 to C4 interfaces are configured as 100GE QSFP28 interfaces. You can use the following command to convert them to 40GE QSFP+ interfaces. Once converted, you can use the other command below to split them into four 10GBASE-SR interfaces.

Changing the interface type

For example, to change the interface type of the C1 interface of the FIM-7920E in slot 1 to 40GE QSFP+ connect to the CLI of your FortiGate-7000 system using the management IP and enter the following command:

```
config system global
   set qsfp28-40g-port 1-C1
end
```

The FortiGate-7000 system reboots and when it starts up interface C1 of the FIM-7920E in slot 1 is operating as a 40GE QSFP+ interface .

To change the interface type of the C3 and C4 ports of the FIM-7920E in slot 2 to 40GE QSFP+ enter the following command:

```
config system global
   set qsfp28-40g-port 2-C3 2-C4
end
```

The FortiGate-7000 system reboots and when it starts up interfaces C3 and C4 of the FIM-7920E in slot 2 are operating as a 40GE QSFP+ interfaces.

Splitting the C1 to C4 interfaces

Each 40GE interface (C1 to C4) on the FIM-7920Es in slot 1 and slot 2 of a FortiGate-7000 system can be split into 4 x 10GBE interfaces. You split these interfaces after the FIM-7920Es are installed in your FortiGate-7000 system and the system us up and running. You can split the interfaces of the FIM-7920Es in slot 1 and slot 2 at the same time by entering a single CLI command. Splitting the interfaces requires a system reboot so Fortinet recommends that you split multiple interfaces at the same time according to your requirements to avoid traffic disruption.

For example, to split the C1 interface of the FIM-7920E in slot 1 (this interface is named 1-C1) and the C1 and C4 interfaces of the FIM-7920E in slot 2 (these interfaces are named 2-C1 and 2-C4) connect to the CLI of your FortiGate-7000 system using the management IP and enter the following command:

```
config system global
   set split-port 1-C1 2-C1 2-C4
end
```

After you enter the command, the FortiGate-7000 reboots and when it comes up:

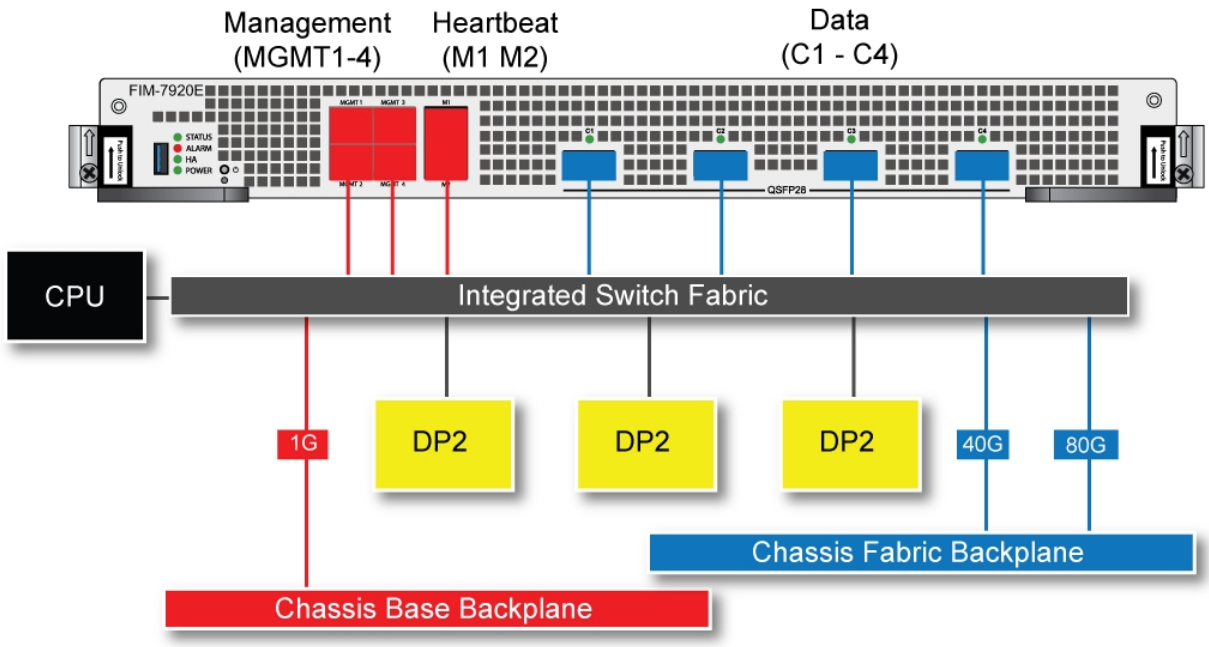
- The 1-C1 interface will no longer be available. Instead the 1-C1/1, 1-C1/2, 1-C1/3, and 1-C1/4 interfaces will be available.
- The 2-C1 interface will no longer be available. Instead the 2-C1/1, 2-C1/2, 2-C1/3, and 2-C1/4 interfaces will be available.
- The 2-C4 interface will no longer be available. Instead the 2-C4/1, 2-C4/2, 2-C4/3, and 2-C4/4 interfaces will be available.

You can now connect breakout cables to these interfaces and configure traffic between them just like any other FortiGate interface.

FIM-7920E hardware schematic

The FIM-7920E includes an integrated switch fabric (ISF) that connects the front panel interfaces to the DP2 session-aware load balancers and to the chassis backplanes. The ISF also allows the DP2 processors to distribute sessions among all NP6 processors on the FortiGate Processor Modules (FPM) in the FortiGate-7000 chassis.

FIM-7920E hardware schematic



FPM-7620E processing module

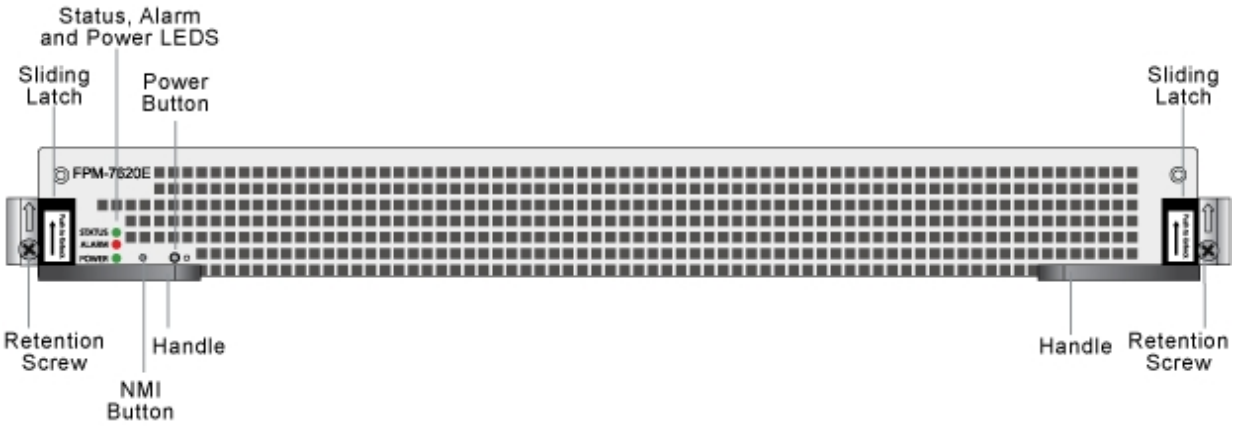
The FPM-7620E processing module is a high-performance worker module that processes sessions load balanced to it by FortiGate-7000 series interface (FIM) modules over the chassis fabric backplane. The FPM-7620E can be installed in any FortiGate-7000 series chassis in slots 3 and up.

The FPM-7620E includes two 80Gbps connections to the chassis fabric backplane and two 1Gbps connections to the base backplane. The FPM-7620E processes sessions using a dual CPU configuration, accelerates network traffic processing with 4 NP6 processors and accelerates content processing with 8 CP9 processors. The NP6 network processors are connected by the FIM switch fabric so all supported traffic types can be fast path accelerated by the NP6 processors.

The FPM-7620E includes the following hardware features:

- Two 80Gbps fabric backplane channels for load balanced sessions from the FIMs installed in the chassis.
- Two 1Gbps base backplane channels for management, heartbeat and session sync communication.
- Dual CPUs for high performance operation.
- Four NP6 processors to offload network processing from the CPUs.
- Eight CP9 processors to offload content processing and SSL and IPsec encryption from the CPUs.

FPM-7620E front panel

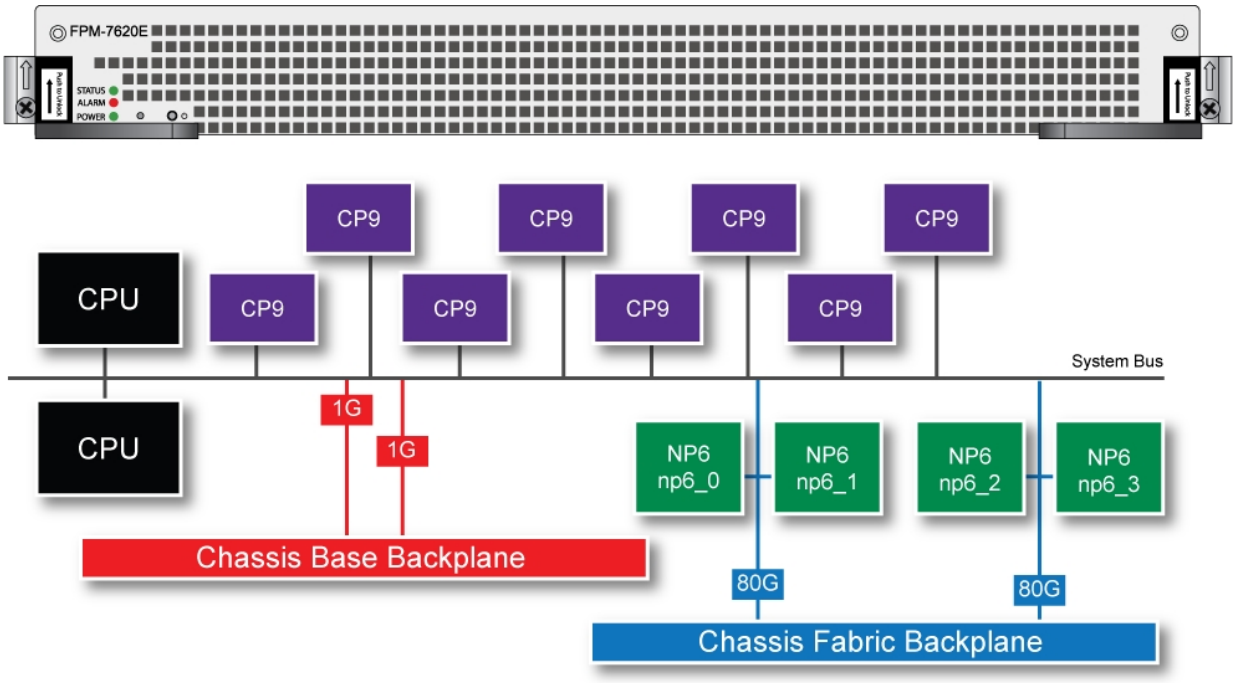


- Power button.
- NMI switch (for troubleshooting as recommended by Fortinet Support).
- Mounting hardware.
- LED status indicators.

NP6 network processors - offloading load balancing and network traffic

In a FortiGate-7000 chassis, FPM-7620E NP6 network processors combined with the FortiGate Interface Module (FIM) Integrated Switch Fabric (ISF) provide hardware acceleration by offloading sessions from the FPM-7620E CPUs. The result is enhanced network performance provided by the NP6 processors plus the removal of network processing load from the FPM-7620 CPUs. The NP6 processors can also handle some CPU-intensive tasks, like IPsec VPN encryption/decryption. Because of the ISF in each FIM, all sessions are fast-pathed and accelerated.

FPM-7620E hardware architecture



Accelerated IPS, SSL VPN, and IPsec VPN (CP9 content processors)

The FPM-7620E includes eight CP9 processors that provide the following performance enhancements:

- Flow-based inspection (IPS, application control etc.) pattern matching acceleration with over 10Gbps throughput
  - IPS pre-scan
  - IPS signature correlation
  - Full match processors
- High performance VPN bulk data engine
  - IPsec and SSL/TLS protocol processor
  - DES/3DES/AES128/192/256 in accordance with FIPS46-3/FIPS81/FIPS197
  - MD5/SHA-1/SHA256/384/512-96/128/192/256 with RFC1321 and FIPS180
  - HMAC in accordance with RFC2104/2403/2404 and FIPS198
  - ESN mode
  - GCM support for NSA "Suite B" (RFC6379/RFC6460) including GCM-128/256; GMAC-128/256
- Key Exchange Processor that supports high performance IKE and RSA computation
  - Public key exponentiation engine with hardware CRT support
  - Primary checking for RSA key generation
  - Handshake accelerator with automatic key material generation
  - True Random Number generator
  - Elliptic Curve support for NSA "Suite B"
  - Sub public key engine (PKCE) to support up to 4096 bit operation directly (4k for DH and 8k for RSA with CRT)
- DLP fingerprint support
  - TTTD (Two-Thresholds-Two-Divisors) content chunking
  - Two thresholds and two divisors are configurable

Getting started with FortiGate-7000

Once you have installed your FortiGate-7000 chassis in a rack and installed FIM interface modules and FPM processing modules in it you can power on the chassis and all modules in the chassis will power up.

Whenever a chassis is first powered on, it takes about 5 minutes for all modules to start up and become completely initialized and synchronized. During this time the chassis will not allow traffic to pass through and you may not be able to log into the GUI, or if you manage to log in the session could time out as the FortiGate-7000 continues negotiating.

Review the chassis and module front panel LEDs to verify that everything is operating normally. Wait until the chassis has complete started up and synchronized before making configuration changes.

You can use the `diagnose sys ha status` command to confirm that the FortiGate-7000 is completely initialized. If the output from entering this command hasn't changed after checking for a few minutes you can assume that the system has initialized. You don't normally have to confirm that the system has initialized, but this diagnose command is available to verify that the system is initialized.

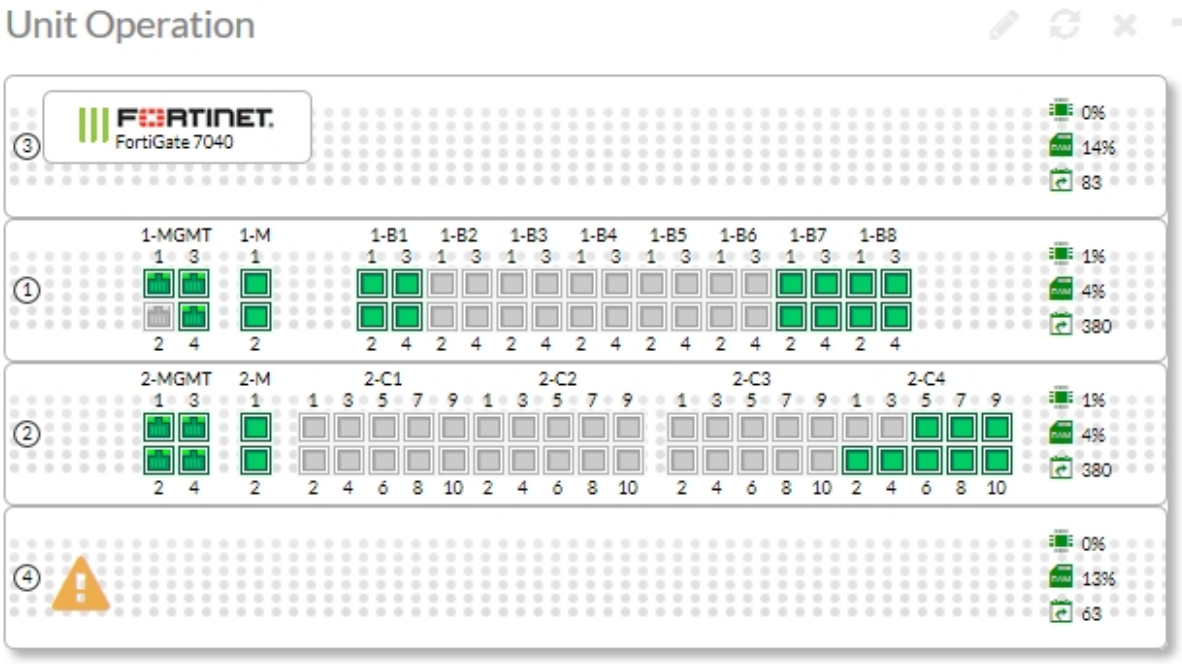
Once the system has initialized you have a few options for connecting to the FortiGate-7000 GUI or CLI:

- Log into the GUI by connecting the MGMT1 interface of the FIM in slot 1 to your network. Then browse to https://192.168.1.99. The default administrator account is **admin** with no password. For more information about using the MGMT interfaces for management connections to the FortiGate-7000, see Setting up management connections on page 823.
- Log into the CLI by connecting the MGMT1 interface of the FIM in slot 1 to your network. Then use an SSH client to connect to 192.168.1.99 and use the same admin account to log in.
- Log into the CLI with a serial connection to the Console 1 serial port on the FortiGate-7000 management module. For more information, including the serial port settings, see Connecting to module CLIs using the management module on page 826.

The following example Unit Operation dashboard widget shows a FortiGate-7040E with the following modules:

- An FIM-7904E in slot 1. Each of the FIM-7904E B1 to B8 front panel interfaces has been split into four interfaces
- An FIM-7910E in slot 2. Each of the FIM0-7910E C1 to C4 front panel interfaces has been split into ten interfaces.
- FPM-7620Es in slots 3 and 4.

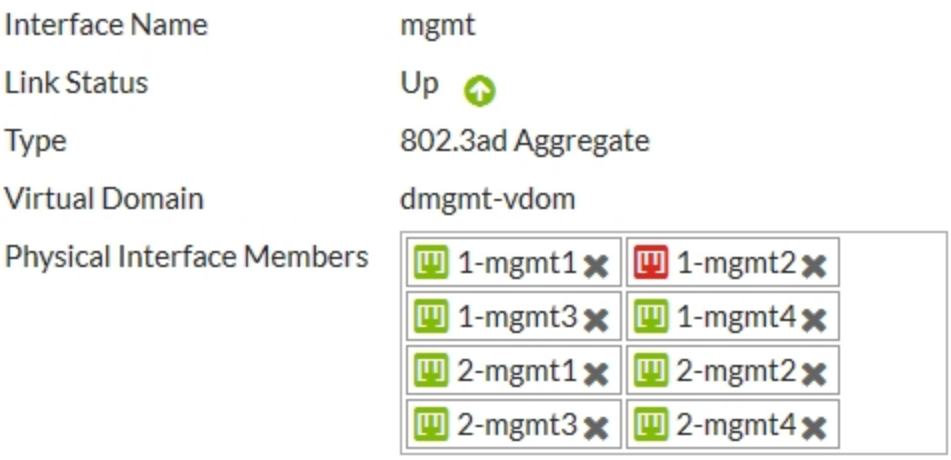
Example FortiGate-7040 unit operation widget view



Setting up management connections

When your FortiGate-7000 first starts up, the MGMT1 to MGMT4 ports of both of the FIMs are part of a static 802.3 aggregate interface with a default IP address of 192.168.1.99. On the GUI or CLI the 802.3 aggregate interface is named **mgmt**.

Example mgmt management interface configuration



Setting up a single management connection

You can configure and manage your FortiGate-7000 by connecting an Ethernet cable to any of the MGMT1 - 4 interfaces of the FIM in slot 1 or slot 2 and logging into the GUI using HTTPS or the CLI using SSH. The default

IP address is 192.168.1.99 and you can log in with the **admin** administrator account with no password.

For security reasons you should add a password to the admin account before connecting the chassis to your network.

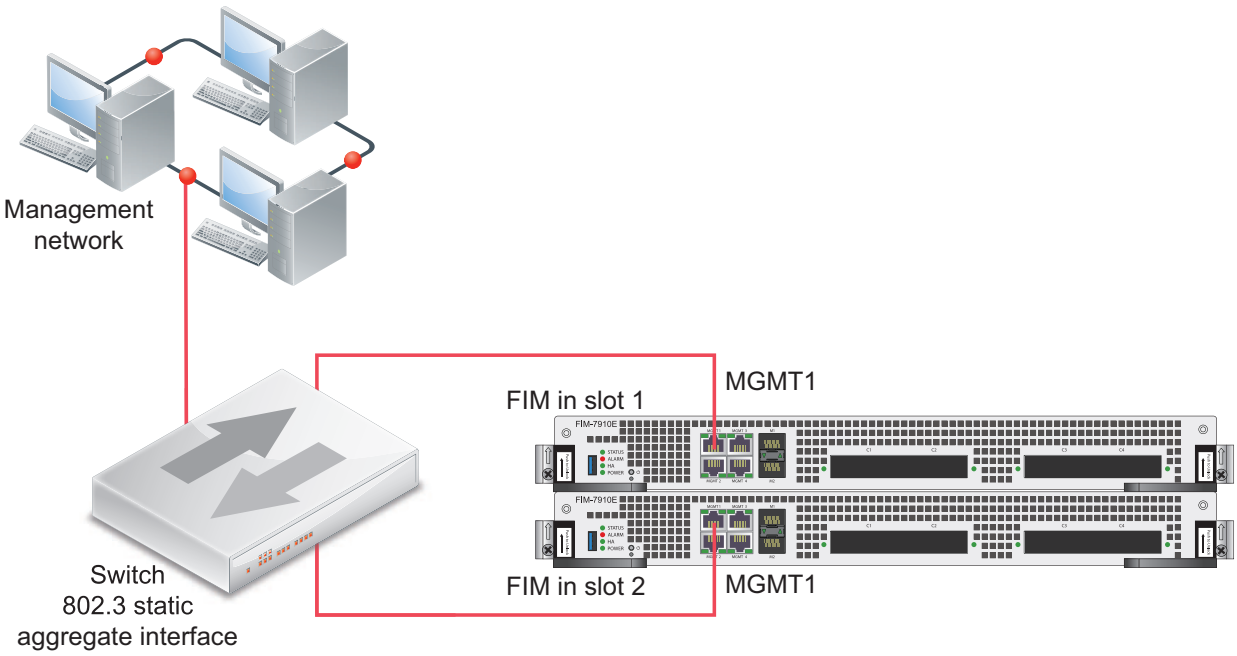
Setting up redundant management connections

You can set up redundant management connections to your FortiGate-7000 by adding a static 802.3 aggregate interface to a switch and setting up multiple connections between the switch and the FIM MGMT ports. Then connect the switch to your network.

LACP is not supported for the mgmt aggregate interface.

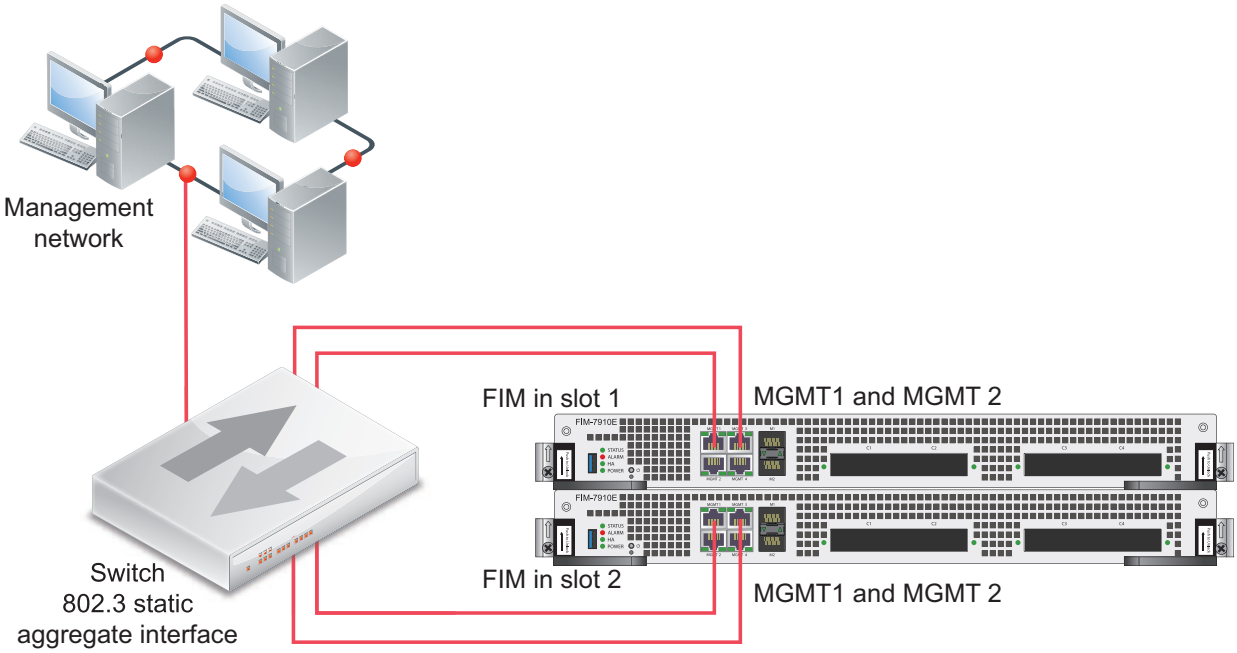
You do not have the change the configuration of the FortiGate-7000 to set up redundant management connections. The following example shows connections between the MGMT 1 interfaces of each FIM to a switch. The switch is configured with a 802.3 static aggregate interface that includes two ports, one for each MGMT 1 interface. The switch also connects the MGMT 1 interfaces to a management network.

Example FortiGate-7000 redundant management connections



The following example shows redundant connections between both FIMs and the switch. In this case you need to add more switch ports to the static aggregate interface on the switch. You do not have to change the configuration of the FortiGate-7000 to set up this redundant management connection configuration.

Example FortiGate-7000 redundant management connections with redundant connections to each FIM



In either of these configurations, for additional redundancy you can use two switches. If you use two redundant switches, the static aggregate interface should span across both switches.

Managing individual FIMs and FPMs

When you log into the GUI or CLI using the mgmt interface IP address you are actually connected to the primary (or master) FIM in slot 1 (the address of slot 1 is FIM01). To verify which module you have logged into, the GUI header banner or CLI prompt shows the hostname of the module you are logged into plus the slot address in the format <hostname> (<slot address>).

In some cases you may want to connect to individual modules. For example, you may want to view the traffic being processed by a specific FPM. You can connect to the GUI or CLI of individual modules in the chassis using the system management IP address with a special port number.

For example, if the system management IP address is 192.168.1.99 you can connect to the GUI of the FIM in slot 1 using the system management IP address (for example, by browsing to https://192.168.1.99). You can also use the system management IP address followed by the special port number, for example https://192.168.1.99:44301.

The special port number (in this case 44301) is a combination of the service port (for HTTPS the service port is 443) and the chassis slot number (in this example, 01). The following table lists the special ports to use to connect to each chassis slot using common admin protocols:

FortiGate-7000 special administration port numbers

Slot Number	Slot Address	HTTP (80)	HTTPS (443)	Telnet (23)	SSH (22)	SNMP (161)
5	FPM05	8005	44305	2305	2205	16105
3	FPM03	8003	44303	2303	2203	16103
1	FIM01	8001	44301	2301	2201	16101
2	FIM02	8002	44302	2302	2202	16102
4	FPM04	8004	44304	2304	2204	16104
6	FPM06	8006	44306	2306	2206	16106

For example:

- To connect to the GUI of the FIM in slot 3 using HTTPS you would browse to https://192.168.1.99:44303.
- To send an SNMP query to the FPM in slot 6 use the port number 16106.

The FortiGate-7000 configuration is the same no matter which modem you log into. Logging into different modules allows you to use FortiView or Monitor GUI pages to view the activity on that module. Even though you can log into different modules, you should only make configuration changes from the primary FIM; which is the FIM in slot 1.

Managing individual modules from the CLI

From the CLI you can use the following command to switch between chassis slots and perform different operations on the modules in each slot:

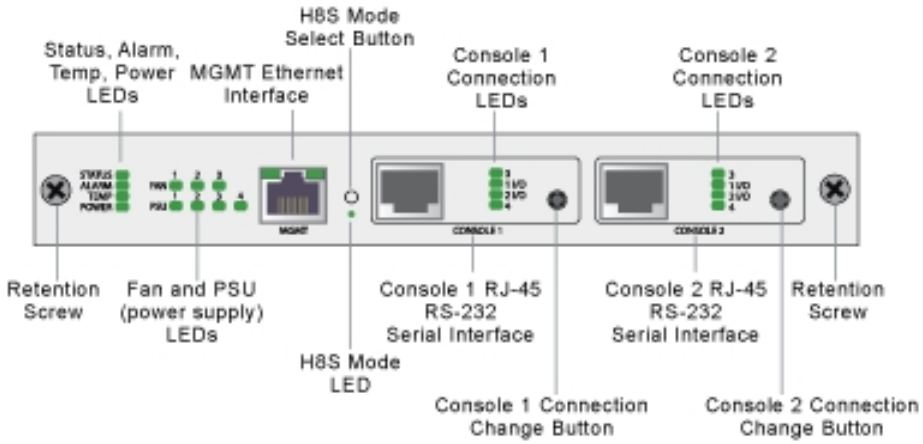
```
execute load-balance slot {manage | power-off | power-on | reboot} <slot-number>
```

Use `manage` to connect to the CLI of a different module, use `power-off`, `power-on`, and `reboot` to turn off or turn on the power or reboot the module in `<slot-number>`.

Connecting to module CLIs using the management module

All FortiGate-7000 chassis includes a front panel management module (also called a shelf manager) on the chassis front panel. See the system guide for your chassis for details about the management module.

ForiGate-7040E management module front panel



The management module includes two console ports named Console 1 and Console 2 that can be used to connect to the CLI of the FIM and FPMs in the chassis. As described in the system guide, the console ports are also used to connect to SMC CLIs of the management module and the FIM and FPMs

By default when the chassis first starts up Console 1 is connected to the FortiOS CLI of the FIM in slot 1 and Console 2 is disconnected. The default settings for connecting to each console port are:

Baud Rate (bps) 9600, Data bits 8, Parity None, Stop bits 1, and Flow Control None.

You can use the console connection change buttons to select the CLI that each console port is connected to. Press the button to cycle through the FIM and FPM FortiOS CLIs and disconnect this console. The console's LEDs indicate what it is connected to. If no LED is lit the console is either connected to the management module SMC SDI console or disconnected. Both console ports cannot be connected to the same CLI at the same time. If a console button press would cause a conflict that module is skipped. If one of the console ports is disconnected then the other console port can connect to any CLI.

If you connect a PC to one of the management module console ports with a serial cable and open a terminal session you begin by pressing Ctrl-T to enable console switching mode. Press Ctrl-T multiple times to cycle through the FIM and FPM FortiOS CLIs (the new destination is displayed in the terminal window). If you press Ctrl-T after connecting to the FPM in the highest slot number, the console is disconnected. Press Ctrl-T again to start over again at slot 1.

Once the console port is connected to the CLI that you want to use, press Enter to enable the CLI and login. The default administrator account for accessing the FortiOS CLIs is admin with no password.

When your session is complete you can press Ctrl-T until the prompt shows you have disconnected from the console.

Connecting to the FortiOS CLI of the FIM in slot 1

Use the following steps to connect to the FortiOS CLI of the FIM in slot 1:

1. Connect the console cable supplied with your chassis to Console 1 and to your PC or other device RS-232 console port.
2. Start a terminal emulation program on the management computer. Use these settings:
   Baud Rate (bps) 9600, Data bits 8, Parity None, Stop bits 1, and Flow Control None.

3. Press Ctrl-T to enter console switch mode.
4. Repeat pressing Ctrl-T until you have connected to slot 1. Example prompt:
   ```
   <Switching to Console: FIM01 (9600)>
   ```
5. Login with an administrator name and password.
   The default is admin with no password. For security reasons, it is strongly recommended that you change the password.
6. When your session is complete, enter the `exit` command to log out.

Default VDOM configuration

By default when the FortiGate-7000 first starts up it is operating in multiple VDOM mode. The system has a management VDOM (named dmgmt-vdom) and the root VDOM. All management interfaces are in dmgmt-vdom and all other interfaces are in the root VDOM. You can add more VDOMs and add interfaces to them or just use the root VDOM.

Default management VDOM

By default the FortiGate-7000 configuration includes a management VDOM named dmgmt-vdom. For the FortiGate-7000 system to operate normally you should not change the configuration of this VDOM and this VDOM should always be the management VDOM. You should also not add or remove interfaces from this VDOM.

You have full control over the configurations of other FortiGate-7000 VDOMs.

Firmware upgrades

All of the modules in your FortiGate-7000 run the same firmware image. You upgrade the firmware from the primary FIM GUI or CLI just as you would any FortiGate product. During the upgrade process the firmware of all of the modules in the chassis upgrades in one step. Firmware upgrades should be done during a quiet time because traffic will briefly be interrupted during the upgrade process.

Before beginning a firmware upgrade, Fortinet recommends the following:

- Review the latest release notes for the firmware version that you are upgrading to.
- Verify the recommended upgrade path as documented in the release notes.
- Backup your FortiGate-7000 HA configuration.
- Review the services provided by your FortiGate-7000 before the upgrade and then again after the upgrade to make sure everything continues to operate normally. For example, you might want to verify that you can successfully access a key server used by your organization before the upgrade and make sure after the upgrade that you can still reach the server and that performance is comparable. You could also take a snapshot of key performance indicators (number of sessions, CPU usage, and memory usage) before the upgrade and verify that you see comparable performance after the upgrade .

For information about upgrading FortiGate-7000 HA configuration, see Upgrading FortiGate-7000 HA cluster firmware on page 856.

Restarting the FortiGate-7000

To restart all of the modules in a FortiGate-7000 chassis, connect to the primary FIM CLI and enter the command `execute reboot`. When you enter this command all of the modules in the chassis reboot.

You can restart individual modules by logging into that module's CLI and entering the `execute reboot` command.

Configuration synchronization

The FortiGate-7000 synchronizes the configuration to all modules in the chassis. To support this feature, the FIM in slot 1 becomes the config-sync master and this FIM makes sure the configurations of all modules are synchronized. Every time you make a configuration change you must be logged into the chassis using the management address, which logs you into the config-sync master. All configuration changes made to the config-sync master are synchronized to all of the modules in the chassis.

If the FIM in slot 1 fails or reboots, the FIM in slot 2 becomes the config-sync master.

Packet sniffing for FIM and FPM packets

You can use the `diagnose sniffer packet` command to view or sniff packets as they are processed by FIM or FPMs. To use this command you have to be logged into a VDOM. You can run this command from any FIM or FPM CLI.

If you run the command from the primary FIM you can use the `<slot>` option to view packets for the module in that slot. If you run the command from an individual FIM or FPM the `<slot>` option is not available and you see only the packets processed by that module.

From an FIM the command syntax is:

```
diagnose sniffer packet <interface> <protocol-filter> <verbose> <count> <timestamp> <slot>
```

Where:

`<interface>` is the name of one or more interfaces on which to sniff for packets. Use `any` to sniff packets for all interfaces. To view management traffic use the `elbc-base-ctrl` interface name.

`<protocol-filter>` a filter to select the protocol for which to view traffic. This can be simple, such as entering `udp` to view UDP traffic or complex to specify a protocol, port, and source and destination interface and so on.

<verbose> the amount of detail in the output, and can be:

1 display packet headers only.

2 display packet headers and IP data.

3 display packet headers and Ethernet data (if available).

4 display packet headers and interface names.

5 display packet headers, IP data, and interface names.

6 display packet headers, Ethernet data (if available), and interface names.

`<count>` the number of packets to view. You can enter Ctrl-C to stop the sniffer before the count is reached.

`<timestamp>` the timestamp format, `a` for UTC time and `l` for local time.

When you press Enter you are prompted to run the packet capture on the module that you have logged into or you can input a slot number (for example, `slot2`) to capture packets on the module in that slot.

Load balancing and flow rules

This chapter provides an overview of how FortiGate-7000 Session-Aware Load Balancing (SLBC) works and then breaks down the details and explains why you might want to change some load balancing settings.

FortiGate-7000 SLBC works as follows.

1. SLBC attempts to match all incoming sessions with a configured flow rule (see Load balancing and flow rules on page 830). If a session matches a flow rule, the session is directed according to the action setting of the flow rule. Usually flow rules send traffic that can't be load balanced to a specific FPM.
2. TCP, UDP, SCTP, ICMP (IPv4 only) and ESP (IPv4 only) sessions that do not match a flow rule are directed to the DP2 processors.
   The DP2 processors distribute sessions to the FPMs according to the load balancing method set by the `dp-load-distribution-method` option of the `config load-balance setting` command.
3. All other sessions are sent to the primary FPM.

Setting the load balancing method

Sessions are load balanced or distributed based on the load balancing method set by the following command:

```
config load-balance setting
   set dp-load-distribution-method {to-master | src-ip | dst-ip | src-dst-ip | src-ip-
       sport | dst-ip-dport | src-dst-ip-sport-dport}
   end
```

Where:

`to-master` directs all session to the primary FPM. This method is for troubleshooting only and should not be used for normal operation. Directing all sessions to the primary FPM will have a negative impact on performance.

`src-ip` sessions are distributed across all FPMs according to their source IP address.

`dst-ip` sessions are statically distributed across all FPMs according to their destination IP address.

`src-dst-ip` sessions are distributed across all FPMs according to their source and destination IP addresses.

`src-ip-sport` sessions are distributed across all FPMs according to their source IP address and source port.

`dst-ip-dport` sessions are distributed across all FPMs according to their destination IP address and destination port.

`src-dst-ipsport-dport` sessions are distributed across all FPMs according to their source and destination IP address, source port, and destination port. This is the default load balance algorithm and represents true session-aware load balancing. All session information is taken into account when deciding where to send new sessions and where to send additional packets that are part of an already established session.

The `src-ip` and `dst-ip` load balancing methods use layer 3 information (IP addresses) to identify and load balance sessions. All of the other load balancing methods (except for `to-master`) use both layer 3 and layer 4 information (IP addresses and port numbers) to identify a TCP and UDP session. The layer 3 and layer 4 load balancing methods only use layer 3 information for other types of traffic (SCTP, ICMP, and ESP). If GTP load balancing is enabled, Tunnel Endpoint Identifiers (TEIDs) are used to identify GTP sessions.

Flow rules for sessions that cannot be load balanced

Some traffic types cannot be load balanced. Sessions for traffic types that cannot be load balanced should normally be sent to the primary (or master) FPM by configuring flow rules for that traffic. You can also configure

flow rules to send traffic that cannot be load balanced to specific FPMs.

Create flow rules using the `config loadbalance flow-rule` command. The default configuration uses this command to send IKE, GRE, session helper, Kerberos, BGP, RIP, IPv4 and IPv6 DHCP, PPTP, BFD, IPv4 multicast and IPv6 multicast to the primary FPM. You can view the default configuration of the `config loadbalance flow-rule` command to see how this is all configured. For example, the following configuration sends all IKE sessions to the primary FPM:

```
config load-balance flow-rule
   edit 1
      set status enable
      set vlan 0
      set ether-type ip
      set protocol udp
      set src-l4port 500-500
      set dst-l4port 500-500
      set action forward
      set forward-slot master
      set priority 5
      set comment "ike"
   next
   edit 2
      set status disable
      set vlan 0
      set ether-type ip
      set protocol udp
      set src-l4port 4500-4500
      set dst-l4port 0-0
      set action forward
      set forward-slot master
      set priority 5
      set comment "ike-natt src"
   next
   edit 3
      set status disable
      set vlan 0
      set ether-type ip
      set protocol udp
      set src-l4port 0-0
      set dst-l4port 4500-4500
      set action forward
      set forward-slot master
      set priority 5
      set comment "ike-natt dst"
   next
```

See Default configuration for traffic that cannot be load balanced on page 833 for a listing of all of the default configuration flow rules.

Determining the primary FPM

You can use the `diagnose load-balance status` command to determine which FPM is operating as the primary FPM. The primary FPM is also responsible for dynamic routing.

Example `diagnose load-balance status` output for a FortiGate-7060E showing that the FPM in slot 3 is the primary (master) FPM. The command output also shows the status of all of the FPMs in the FortiGate-7060E. The output also shows that the FPM in slot 4 is either missing or down.

```
diagnose load-balance status
================================================================================
Slot: 2  Module SN: FIM04E3E16000222
  FIM02: FIM04E3E16000222
  Master FPM Blade: slot-3

     Slot  3: FPM20E3E17900133
       Status:Working   Function:Active
       Link:      Base: Up          Fabric: Up
       Heartbeat: Management: Good   Data: Good
       Status Message:"Running"
     Slot  4:
       Status:Dead      Function:Active
       Link:      Base: Up          Fabric: Down
       Heartbeat: Management: Failed Data: Failed
       Status Message:"Waiting for management heartbeat."
.
.
.
```

IPsec VPN load balancing

You can use the following command to enable or disable IPsec VPN load balancing:

```
config load-balance setting
   config ipsec-load-balance {disable | enable}
end
```

By default IPsec VPN load balancing is enabled and the flow rules listed below are disabled. So the IPsec VPN sessions is directed to the DP2 processors and load balanced to the FPMs.

However, IPsec VPN load balancing enabled, IPsec VPN sessions traveling between two IPsec tunnels will be dropped because the two IPsec tunnels may be terminated on different FPMs. So if you have traffic entering the FortiGate-7000 from one IPsec VPN tunnel and leaving the FortiGate-7000 out another IPsec VPN tunnel you need to disable IPsec load balancing:

```
config load-balance setting
   config ipsec-load-balance disable
end
```

The following flow rules are enabled if IPsec VPN load balancing is disabled:

```
config load-balance flow-rule
    edit 22
        set ether-type ipv4
        set protocol udp
        set src-l4port 500-500
        set dst-l4port 500-500
        set comment "ipv4 ike"
    next
    edit 23
        set ether-type ipv4
        set protocol udp
        set src-l4port 4500-4500
        set comment "ipv4 ike-natt src"
    next
```

```
    edit 24
        set ether-type ipv4
        set protocol udp
        set dst-l4port 4500-4500
        set comment "ipv4 ike-natt dst"
    next
    edit 25
        set ether-type ipv4
        set protocol esp
        set comment "ipv4 esp"
    next
end
```

These flow rules should generally handle all IPsec VPN traffic. You can also adjust them or add your own flow rules if you have an IPsec VPN setup that is not compatible with the default flow rules.

GTP load balancing

You can use the following command to enable or disable GTP load balancing.

```
config load-balance setting
  config gtp-load-balance {disable | enable}
end
```

By default, this option is disabled and GTP load balancing is disabled. The following flow rule is enabled and GTP traffic is directed to the primary (master) FPM.

```
config load-balance flow-rule
    edit 17
        set ether-type ipv4
        set protocol udp
        set dst-l4port 2123-2123
        set comment "gtp-c to master blade"
    next
end
```

When the `gtp-load-balance` option is enabled, the GTP load balancing is flow rule is disabled and GTP sessions are directed to the DP2 processors and load balanced to the FPMs.

Default configuration for traffic that cannot be load balanced

The following flow rules are recommended to handle common forms of traffic that cannot be load balanced. These flow rules send GPRS (port 2123), SSL VPN, IPv4 and IPv6 IPsec VPN, ICMP and ICMPv6 traffic to the primary (or master) FPM.

The CLI syntax below just shows the configuration changes. All other options are set to their defaults. For example, the flow rule option that controls the FPM slot that sessions are sent to is `forward-slot` and in all cases below `forward-slot` is set to its default setting of `master`. This setting sends matching sessions to the primary (or master) FPM.

```
config load-balance flow-rule
  edit 20
     set status enable
     set ether-type ipv4
     set protocol udp
     set dst-l4port 2123-2123
  next
  edit 21
```

```
        set status enable
        set ether-type ip
        set protocol tcp
        set dst-l4port 10443-10443
        set comment "ssl vpn to the primary FPM"

    end
```

Operating a FortiGate-7000

This chapter describes some FortiGate-7000 general operating procedure.

Failover in a standalone FortiGate-7000

A FortiGate-7000 will continue to operate even if one of the FIM or FPMs fails or is removed. If an FPM fails, sessions being processed by that module fail. All sessions are then load balanced to the remaining FPMs. Sessions that were being processed by the failed module are restarted and load balanced to the remaining FPMs.

If an FIM fails, the other FIM will continue to operate and will become the config-sync master. However, traffic received by the failed FIM will be lost.

You can use LACP or redundant interfaces to connect interfaces of both FIMs to the same network. In this way, if one of the FIMs fails the traffic will continue to be received by the other FIM.

Replacing a failed FPM or FIM

This section describes how to remove a failed FPM or FIM and replace it with a new one. The procedure is slightly different depending on if you are operating in HA mode with two chassis or just operating a standalone chassis.

Replacing a failed module in a standalone FortiGate-7000 chassis

1. Power down the failed module by pressing the front panel power button.
2. Remove the module from the chassis.
3. Insert the replacement module. It should power up when inserted into the chassis if the chassis has power.
4. The module's configuration is synchronized and its firmware is upgraded to match the firmware version on the primary module. The new module reboots.
5. Confirm that the new module is running the correct firmware version either from the GUI or by using the `config system status` command.
   Manually update the module to the correct version if required. You can do this by logging into the module and performing a firmware upgrade.
6. Verify that the configuration has been synchronized.
   The following command output shows the sync status of the FIMs in a FortiGate-7000 chassis. The field `in_sync=1` indicates that the configurations of the modules are synchronized.

   ```
   diagnose sys confsync
   status | grep in_sy
   FIM04E3E16000080, Slave, uptime=177426.45, priority=2,
   slot_id=1:2, idx=0, flag=0x0, in_sync=1
   FIM10E3E16000063, Master, uptime=177415.38, priority=1,
   slot_id=1:1, idx=1, flag=0x0, in_sync=1
   ```

   If `in_sync` is not equal to 1 or if a module is missing in the command output you can try restarting the modules in the chassis by entering execute reboot from any module CLI. If this does not solve the problem, contact Fortinet support.

Replacing a failed module in a FortiGate-7000 chassis in an HA cluster

1. Power down the failed module by pressing the front panel power button.
2. Remove the module from the chassis.
3. Insert the replacement module. It should power up when inserted into the chassis if the chassis has power.

4. The module's configuration is synchronized and its firmware is upgraded to match the configuration and firmware version on the primary module. The new module reboots.
5. Confirm that the module is running the correct firmware version.
   Manually update the module to the correct version if required. You can do this by logging into the module and performing a firmware upgrade.
6. Configure the new module for HA operation. For example:
```
config system ha
   set mode a-p
   set chassis-id 1
   set hbdev m1 m2
   set hbdev-vlan-id 999
   set hbdev-second-vlan-id 990
end
```
7. Optionally configure the hostname:
```
config system global
   set hostname <name>
end
```
   The HA configuration and the hostname must be set manually because HA settings and the hostname is not synchronized.
8. Verify that the configuration has been synchronized.
   The following command output shows the sync status of the FIMs in a FortiGate-7000 chassis. The field `in_sync=1` indicates that the configurations of the modules are synchronized.
```
diagnose sys confsync
status | grep in_sy
FIM04E3E16000080, Slave, uptime=177426.45, priority=2,
slot_id=1:2, idx=0, flag=0x0, in_sync=1
FIM10E3E16000063, Master, uptime=177415.38, priority=1,
slot_id=1:1, idx=1, flag=0x0, in_sync=1
```
   If `in_sync` is not equal to 1 or if a module is missing in the command output you can try restarting the modules in the chassis by entering execute reboot from any module CLI. If this does not solve the problem, contact Fortinet support.

Installing firmware on an FIM or FPM from the BIOS using a TFTP server

Use the procedures in this section to install firmware on a FIM or FPM from a TFTP server after interrupting the boot up sequence from the BIOS.

You might want to use this procedure if you need to reset the configuration of a module to factory defaults by installing firmware from a reboot. You can also use this procedure if you have formatted one or more FIM or FPMs from the BIOS by interrupting the boot process.

This procedure involves creating a connection between a TFTP server and one of the MGMT interfaces of one of the FIMs, using a chassis console port to connect to the CLI of the module that you are upgrading the firmware for, rebooting this module, interrupting the boot from the console session, and installing the firmware.

This section includes two procedures, one for upgrading FIMs and one for upgrading FPMs. The two procedures are very similar but a few details, most notably the local VLAN ID setting are different. If you need to update both FIM and FPMs, you should update the FIMs first as the FPMs can only communicate with the TFTP server through FIM interfaces.

Uploading firmware from a TFTP server to an FIM

Use the following steps to upload firmware from a TFTP server to an FIM. This procedure requires Ethernet connectivity between the TFTP server and one of the FIM's MGMT interfaces.

During this procedure, the FIM will not be able to process traffic so, if possible, perform this procedure when the network is not processing any traffic.

If you are operating an HA configuration, you should remove the FortiGate-7000 from the HA configuration before performing this procedure.

1. Set up a TFTP server and copy the firmware file to be installed into the TFTP server default folder.
2. Set up your network to allow traffic between the TFTP server and one of the MGMT interfaces of the FIM to be updated.
   If the MGMT interface you are using is one of the MGMT interfaces connected as a LAG to a switch you must shutdown or disconnect all of the other connections in the LAG from the switch. This includes the MGMT interfaces in the other FIM.
3. Connect the console cable supplied with your chassis to the Console 1 port on your chassis front panel and to your management computer's RS-232 console port.
4. Start a terminal emulation program on the management computer. Use these settings:
   Baud Rate (bps) 9600, Data bits 8, Parity None, Stop bits 1, and Flow Control None.
5. Press Ctrl-T to enter console switch mode.
6. Repeat pressing Ctrl-T until you have connected to the module to be updated. Example prompt:
   `<Switching to Console: FIM02 (9600)>`
7. Optionally log into the FIM's CLI.
8. Reboot the FIM to be updated.
   You can do this using the `execute reboot` command from the CLI or by pressing the power switch on the module front panel.
9. When the FIM starts up, follow the boot process in the terminal session and press any key when prompted to interrupt the boot process.
10. Press `C` to set up the TFTP configuration.
11. Use the BIOS menu to set the following. Only change settings if required.

    `[P]: Set image download port:` MGMT1 (change if required)

    `[D]: Set DHCP mode:` Disabled

    `[I]: Set local IP address:` A temporary IP address to be used to connect to the TFTP server. This address must not be the same as the chassis management IP address and cannot conflict with other addresses on your network

    `[S]: Set local Subnet Mask`: Set as required for your network.

    `[G]: Set local gateway`: Set as required for your network.

    `[V]: Local VLAN ID`: Use -1 to clear the Local VLAN ID.

    `[T]: Set remote TFTP server IP address`: The IP address of the TFTP server.

    `[F]: Set firmware image file name`: The name of the firmware file to be installed.

12. Press Q to quit this menu.

13. Press R to review the configuration.
    If you need to make any corrections, press C and make the changes as required. When the configuration is correct proceed to the next step.
14. Press T to start the TFTP transfer.
    The firmware image is uploaded from the TFTP server and installed on the FIM which then reboots. When it starts up the module's configuration is reset to factory defaults. The module's configuration is synchronized to match the configuration of the primary module. The new module reboots again and can start processing traffic.
15. Verify that the configuration has been synchronized.
    The following command output shows the sync status of the FIMs in a FortiGate-7000 chassis. The field `in_sync=1` indicates that the configurations of the modules are synchronized.

```
diagnose sys confsync
status | grep in_sy
FIM04E3E16000080, Slave, uptime=177426.45, priority=2,
slot_id=1:2, idx=0, flag=0x0, in_sync=1
FIM10E3E16000063, Master, uptime=177415.38, priority=1,
slot_id=1:1, idx=1, flag=0x0, in_sync=1
```

    If `in_sync` is not equal to 1 or if a module is missing in the command output you can try restarting the modules in the chassis by entering execute reboot from any module CLI. If this does not solve the problem, contact Fortinet support.

Uploading firmware from a TFTP server to an FPM

Use the following steps to upload firmware from a TFTP server to an FPM. This procedure requires Ethernet connectivity between the TFTP server and one of the MGMT interfaces of one of the FIMs in the same FortiGate-7000 as the FPM.

During this procedure, the FPM will not be able to process traffic so, if possible, perform this procedure when the network is not processing any traffic. However, the other FPMs and the FIMs in the chassis should continue to operate normally and the chassis can continue processing traffic.

If you are operating an HA configuration, you should remove the FortiGate-7000 from the HA configuration before performing this procedure.

1. Set up a TFTP server and copy the firmware file to be installed into the TFTP server default folder.
2. Set up your network to allow traffic between the TFTP server and a MGMT interface of one of the FIMs in the chassis that also includes the FPM.
   You can use any MGMT interface of either of the FIMs. If the MGMT interface you are using is one of the MGMT interfaces connected as a LAG to a switch you must shutdown or disconnect all of the other connections in the LAG from the switch. This includes the MGMT interfaces in the other FIM.
3. Connect the console cable supplied with your chassis to the Console 1 port on your chassis front panel and to your management computer's RS-232 console port.
4. Start a terminal emulation program on the management computer. Use these settings:
   Baud Rate (bps) 9600, Data bits 8, Parity None, Stop bits 1, and Flow Control None.
5. Press Ctrl-T to enter console switch mode.
6. Repeat pressing Ctrl-T until you have connected to the module to be updated. Example prompt:
   `<Switching to Console: FPM03 (9600)>`
7. Optionally log into the FPM's CLI.
8. Reboot the FPM to be updated.
   You can do this using the `execute reboot` command from the CLI or by pressing the power switch on the module front panel.

9. When the FPM starts up, follow the boot process in the terminal session and press any key when prompted to interrupt the boot process.
10. Press `C` to set up the TFTP configuration.
11. Use the BIOS menu to set the following. Only change settings if required.

    `[P]: Set image download port`: The name of the FIM that can connect to the TFTP server (FIM01 is the FIM in slot 1 and FIM02 is the FIM in slot 2).

    `[D]: Set DHCP mode`: Disabled.

    `[I]: Set local IP address`: A temporary IP address to be used to connect to the TFTP server. This address must not be the same as the chassis management IP address and cannot conflict with other addresses on your network.

    `[S]: Set local Subnet Mask`: Set as required for your network.

    `[G]: Set local gateway`: Set as required for your network.

    `[V]: Local VLAN ID`: The VLAN ID of the FIM interface that can connect to the TFTP server:

    FIM01 local VLAN IDs

Interface	MGMT1	MGMT2	MGMT3	MGMT4
Local VLAN ID	11	12	13	14

    FIM02 local VLAN IDs

Interface	MGMT1	MGMT2	MGMT3	MGMT4
Local VLAN ID	21	22	23	24

    `[T]: Set remote TFTP server IP address`: The IP address of the TFTP server.

    `[F]: Set firmware image file name`: The name of the firmware file to be installed.
12. Press Q to quit this menu.
13. Press R to review the configuration.
    If you need to make any corrections, press C and make the changes as required. When the configuration is correct proceed to the next step.
14. Press T to start the TFTP transfer.
    The firmware image is uploaded from the TFTP server and installed on the FPM which then reboots. When it starts up the module's configuration is reset to factory defaults. The module's configuration is synchronized to match the configuration of the primary module. The new module reboots again and can start processing traffic.
15. Verify that the configuration has been synchronized.
    The following command output shows the sync status of the FIMs in a FortiGate-7000 chassis. The field `in_sync=1` indicates that the configurations of the modules are synchronized.

```
diagnose sys confsync
status | grep in_sy
FIM04E3E16000080, Slave, uptime=177426.45, priority=2,
slot_id=1:2, idx=0, flag=0x0, in_sync=1
FIM10E3E16000063, Master, uptime=177415.38, priority=1,
slot_id=1:1, idx=1, flag=0x0, in_sync=1
```

If `in_sync` is not equal to 1 or if a module is missing in the command output you can try restarting the modules in the chassis by entering execute reboot from any module CLI. If this does not solve the problem, contact Fortinet support.

Viewing interface statistics

From the primary FIM, you can add Interface History dashboard widgets to view traffic in and traffic out and total traffic information about the traffic passing through any FortiGate-7000 interface. You can add an Interface Bandwidth widget to the dashboard for:

- Any physical interface
- Any link aggregation (LAG) interface
- Any member of a LAG
- Any VLAN interface
- Any IPsec VPN tunnel interface
- Any redundant interface

The displayed data includes all of the traffic processed by the interface, independent of how the traffic is load balanced.

You can add individual Interface History widgets for each interface that you want to monitor. When adding the widget you can select the interface to monitor and select different time periods for which to display data. The data displayed on the widget updates in real time if you select enable refresh. You can also scan your cursor over the graph on the widget to see traffic in and out of the interface, and the total traffic for different times on the graph.

From the CLI, for physical interfaces, you can use the `diagnose hardware deviceinfo nic <interface-name>` command to view transmitted and received packets.

For LAG and VLAN interfaces you can display transmitted and received packets using the `diagnose netlink interface list <interface-name>` command.

IPsec VPN

This chapter describes some special FortiGate-6000 routing configurations required to support ForiGate-6000 IPsec VPN configurations.

Adding source and destination subnets to IPsec VPN phase 2 configurations

If your FortiGate-7000 configuration includes IPsec VPNs you should enhance your IPsec VPN Phase 2 configurations as described in this section.

Because the FortiGate-7000 only allows 16-bit to 32-bit routes, you must add one or more destination subnets to your IPsec VPN phase 2 configuration for FortiGate-7000 v5.4.5 using the following command:

```
config vpn ipsec phase2-interface
   edit "to_fgt2"So
      set phase1name <name>
      set src-subnet <IP> <netmask>
      set dst-subnet <IP> <netmask>
   end
```

Where

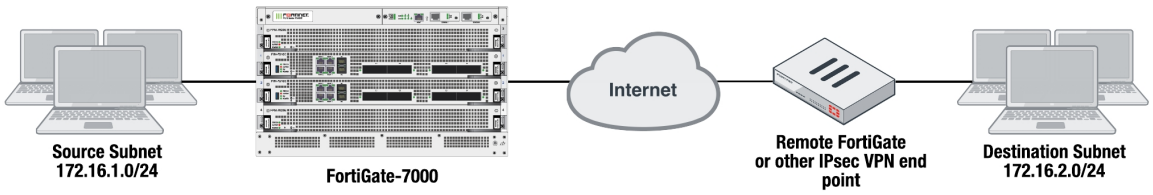
`src-subnet` the subnet protected by the FortiGate that you are configuring and from which users connect to the destination subnet. Configuring the source subnet is optional but recommended.

`dst-subnet` the destination subnet behind the remote IPsec VPN endpoint. Configuring the destination subnet is required.

You can add the source and destination subnets either before or after upgrading to v5.4.5 as these settings are compatible with both v5.4.3 and v5.4.5. However, if you make these changes after upgrading, your IPsec VPNs may not work correctly until these configuration changes are made.

Example basic IPsec VPN phase 2 configuration

In a simple configuration such as the one below with an IPsec VPN between two remote subnets you can just add the subnets to the phase 2 configuration.

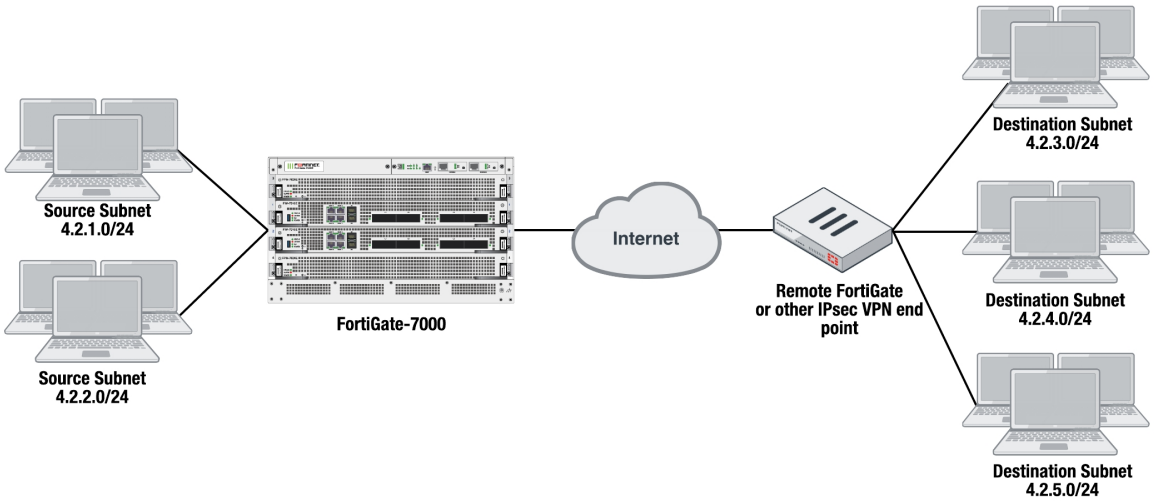


Enter the following command to add the source and destination subnets to the FortiGate-7000 IPsec VPN Phase 2 configuration.

```
config vpn ipsec phase2-interface
   edit "to_fgt2"So
      set phase1name "to_fgt2"
      set src-subnet 172.16.1.0 255.255.255.0
      set dst-subnet 172.16.2.0 255.255.255.0
   end
```

Example multiple subnet IPsec VPN phase 2 configuration

In a more complex configuration, such as the one below with a total of 5 subnets you still need to add all of the subnets to the Phase 2 configuration. In this case you can create a firewall address for each subnet and the addresses to address groups and add the address groups to the Phase 2 configuration.



Enter the following commands to create firewall addresses for each subnet.

```
config firewall address
   edit "local_subnet_1"
      set subnet 4.2.1.0 255.255.255.0
   next
   edit "local_subnet_2"
      set subnet 4.2.2.0 255.255.255.0
   next
   edit "remote_subnet_3"
      set subnet 4.2.3.0 255.255.255.0
   next
   edit "remote_subnet_4"
      set subnet 4.2.4.0 255.255.255.0
   next
   edit "remote_subnet_5"
      set subnet 4.2.5.0 255.255.255.0
   end
```

And then put the five firewall addresses into two firewall address groups.

```
config firewall addrgrp
   edit "local_group"
      set member "local_subnet_1" "local_subnet_2"
   next
   edit "remote_group"
      set member "remote_subnet_3" "remote_subnet_4" "remote_subnet_5"
   end
```

Now, use the firewall address groups in the Phase 2 configuration:

```
config vpn ipsec phase2-interface
   edit "to-fgt2"
```

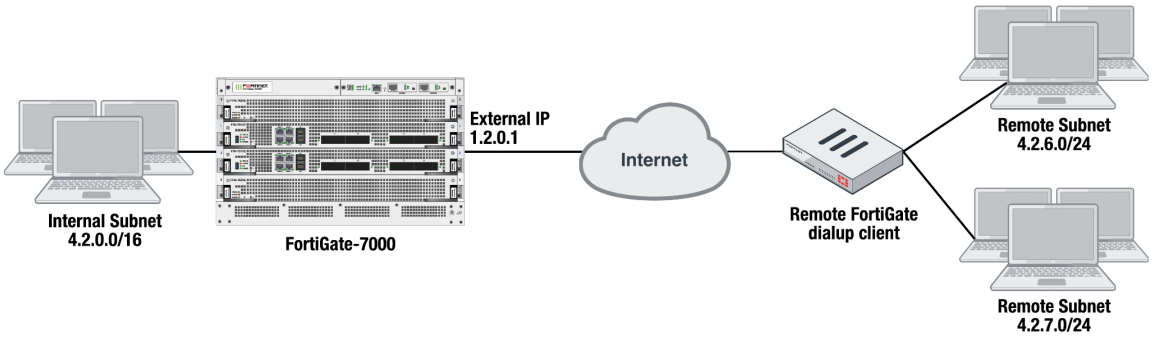
```
        set phase1name "to-fgt2"
        set src-addr-type name
        set dst-addr-type name
        set src-name "local_group"
        set dst-name "remote_group"
    end
```

Configuring the FortiGate-7000 as a dialup IPsec VPN server

FortiGate-7000s running v5.4.5 can be configured as dialup IPsec VPN servers.

Example dialup IPsec VPN configuration

The following shows how to setup a dialup IPsec VPN configuration where the FortiGate-7000 acts as a dialup IPsec VPN server.



To configure the FortiGate-7000 as a dialup IPsec VPN server:

Configure the phase1, set type to dynamic.

```
config vpn ipsec phase1-interface
    edit dialup-server
        set type dynamic
        set interface "v0020"
        set peertype any
        set psksecret < password>
    end
```

Configure the phase 2, to support dialup IPsec VPN, set the destination subnet to 0.0.0.0 0.0.0.0.

```
config vpn ipsec phase2-interface
    edit dialup-server
        set phase1name dialup-server
        set src-subnet 4.2.0.0 255.255.0.0
        set dst-subnet 0.0.0.0 0.0.0.0
    end
```

To configure the remote FortiGate as a dialup IPsec VPN client

The dialup IPsec VPN client should advertise its local subnet(s) using the phase 2 src-subnet option.

If there are multiple local subnets create a phase 2 for each one. Each phase 2 only advertises one local subnet to the dialup IPsec VPN server. If more than one local subnet is added to the phase 2, only the first one is advertised to the server.

Dialup client configuration:

```
config vpn ipsec phase1-interface
   edit "to-fgt7k"
      set interface "v0020"
      set peertype any
      set remote-gw 1.2.0.1
      set psksecret <password>
   end
config vpn ipsec phase2-interface
   edit "to-fgt7k"
      set phase1name "to-fgt7k"
      set src-subnet 4.2.6.0 255.255.255.0
      set dst-subnet 4.2.0.0 255.255.0.0
   next
   edit "to-fgt7k-2"
      set phase1name "to-fgt7k"
      set src-subnet 4.2.7.0 255.255.255.0
      set dst-subnet 4.2.0.0 255.255.0.0
   end
```

Troubleshooting

Use the following commands to verify that IPsec VPN sessions are up and running.

Use the `diagnose load-balance status` command from the primary FIM interface module to determine the primary FPM processor module. For FortiGate-7000 HA, run this command from the primary FortiGate-7000. The third line of the command output shows which FPM is operating as the primary FPM.

```
diagnose load-balance status
  FIM01: FIM04E3E16000074
  Master FPM Blade: slot-4

     Slot  3: FPM20E3E17900113
       Status:Working   Function:Active

Log into the primary FPM CLI and from here log into the VDOM that you added the tunnel configuration to and run the command `diagnose vpn tunnel list <phase2-name>` to show the sessions for the phase 2 configuration. The example below is for the `to-fgt2` phase 2 configuration configured previously in this chapter. The command output shows the security association (SA) setup for this phase 2 and the all of the destination subnets .

From the command output, make sure the SA is installed and the `dst` addresses are correct.

```
CH15 [FPM04] (002ipsecvpn) # diagnose vpn tunnel list name to-fgt2

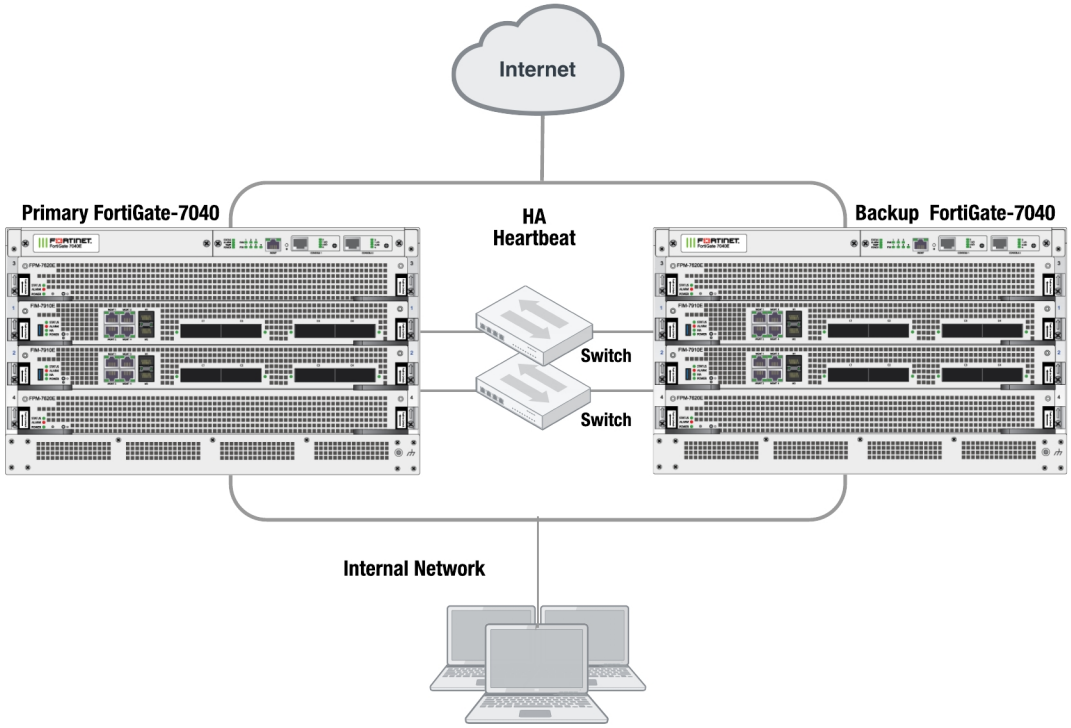
High availability

FortiGate-7000 supports a variation of active-passive FortiGate Clustering Protocol (FGCP) high availability between two identical FortiGate-7000s. With active-passive FortiGate-7000 HA, you create redundant network connections to two identical FortiGate-7000s and add redundant HA heartbeat connections. Then you configure the FIMs in each FortiGate-7000 for HA.The FGCP forms a cluster and selects a primary FortiGate-7000.

Example FortiGate-7040 HA configuration



The primary FortiGate-7000 processes all traffic. The backup FortiGate-7000 operates in hot standby mode. The FGCP synchronizes the configuration, active sessions, routing information, and so on to the backup FortiGate-7000. If the primary FortiGate-7000 fails, traffic automatically fails over to the backup FortiGate-7000.

The FGCP selects the primary FortiGate-7000 based on a number of criteria including the configured priority, the bandwidth, the number of FIM interface failures, and the number of FPM or FIMs that have failed. As part of the HA configuration you assign each FortiGate-7000 a chassis ID and you can set the priority of each FIM and configure module failure tolerances and link failure thresholds.

Before you begin configuring HA

Before you begin, the FortiGate-7000s should be running the same FortiOS firmware version and interfaces should not be configured to get their addresses from DHCP or PPPoE. Register and apply licenses to the each FortiGate-7000 before setting up the HA cluster. This includes licensing for FortiCare, IPS, AntiVirus, Web Filtering, Mobile Malware, FortiClient, FortiCloud, and additional virtual domains (VDOMs). Both FortiGate-7000s in the cluster must have the same level of licensing for FortiGuard, FortiCloud, FortiClient, and VDOMs. FortiToken licenses can be added at any time because they are synchronized to all cluster members.

If required, you should configure split ports on the FIMs on both chassis before configuring HA because the modules have to reboot to enable the split port configuration. For example, to split the C1, C2, and C4 interfaces of an FIM-7910E in slot 1, enter the following command:

```
config system global
   set split-port 1-C1 2-C1 2-C4
end
```

After configuring split ports, the FortiGate-7000 reboots and synchronizes the configuration.

On each FortiGate-7000, make sure configurations of the modules are synchronized before starting to configure HA. You can use the following command to verify that the configurations of all of the modules are synchronized:

```
diagnose sys confsync showchsum | grep all
all: c0 68 d2 67 e1 23 d9 3a 10 50 45 c5 50 f1 e6 8e
all: c0 68 d2 67 e1 23 d9 3a 10 50 45 c5 50 f1 e6 8e
all: c0 68 d2 67 e1 23 d9 3a 10 50 45 c5 50 f1 e6 8e
all: c0 68 d2 67 e1 23 d9 3a 10 50 45 c5 50 f1 e6 8e
all: c0 68 d2 67 e1 23 d9 3a 10 50 45 c5 50 f1 e6 8e
all: c0 68 d2 67 e1 23 d9 3a 10 50 45 c5 50 f1 e6 8e
all: c0 68 d2 67 e1 23 d9 3a 10 50 45 c5 50 f1 e6 8e
all: c0 68 d2 67 e1 23 d9 3a 10 50 45 c5 50 f1 e6 8e
```

If the modules are synchronized, the checksums displayed should all be the same.

You can also use the following command to list the modules that are synchronized. The example output shows all four modules in a FortiGate-7040E have been configured for HA and added to the cluster.

```
diagnose sys configsync status | grep in_sync
Master, uptime=692224.19, priority=1, slot_1d=1:1, idx=0, flag=0x0, in_sync=1
Slave, uptime=676789.70, priority=2, slot_1d=1:2, idx=1, flag=0x0, in_sync=1
Slave, uptime=692222.01, priority=17, slot_1d=1:4, idx=2, flag=0x64, in_sync=1
Slave, uptime=692271.30, priority=16, slot_1d=1:3, idx=3, flag=0x64, in_sync=1
```

In this command output `in_sync=1` means the module is synchronized with the primary FIM and `in_sync=0` means the module is not synchronized.

Connect the M1 and M2 interfaces for HA heartbeat communication

HA heartbeat communication between FortiGate-7000s happens over the 10Gbit M1 and M2 interfaces of the FIMs in each chassis. To set up HA heartbeat connections:

- Connect the M1 interfaces of all FIMs together using a switch.
- Connect the M2 interfaces of all FIMs together using another switch.

All of the M1 interfaces must be connected together with a switch and all of the M2 interfaces must be connected together with another switch. Connecting M1 interfaces or M2 interfaces directly is not supported as each FIM needs to communicate with all other FIMs.

Connect the M1 and M2 interfaces before enabling HA. Enabling HA moves heartbeat communication between the FIMs in the same chassis to the M1 and M2 interfaces. So if these interfaces are not connected before you enable HA, FIMs in the same chassis will not be able to communicate with each other.

Heartbeat packets are VLAN packets with VLAN ID 999 and ethertype 9890. The MTU value for the M1 and M2 interfaces is 1500.

You can use the following command to change the HA heartbeat packet VLAN ID and ethertype values if required for your switches. You must change these settings on each FIM interface module. By default the M1 and M2 interface heartbeat packets use the same VLAN IDs. The following example changes the M1 VLAN ID to 991 and the M2 VLAN ID to 992.

```
config system ha
   set hbdev M1/M2
   set hbdev-vlan-id 991
   set hbdev-second-vlan-id 992
   set ha-eth-type <eth-type>
end
```

For this configuration to work, you must configure both VLAN IDs. You cannot use the default value of 999.

Recommended HA heartbeat interface configuration

For redundancy, Fortinet recommends using separate switches for the M1 and M2 connections.These switches should be dedicated to HA heartbeat communication and not used for other traffic.

If you use the same switch for the M1 and M2 interfaces, separate the M1 and M2 traffic on the switch and set the heartbeat traffic on the M1 and M2 interfaces to have different VLAN IDs.

If you don't set different VLAN IDs for the M1 and M2 heartbeat packets, you must enable q-in-q on the switch.

Sample switch configuration

Sample switch configuration for a Cisco Catalyst switch. This configuration sets the interface speeds, configures the switch to allow vlan 999, and enables trunk mode:

```
##interface config
interface TenGigabitEthernet1/0/5
description Chassis1 FIM1 M1
switchport trunk allowed vlan 999
switchport mode trunk
```

If you are using one switch for both M1 and M2 connections, the configuration would be the same except you would add q-in-q support and two different VLANs, one for M1 traffic and one for M2 traffic.

For the M1 connections:

```
interface Ethernet1/5
description QinQ Test
switchportmode dot1q-tunnel
switchport access vlan 777
spanning-tree port type edge
```

For the M2 connections:

```
interface Ethernet1/5
description QinQ Test
switchport mode dot1q-tunnel
switchport access vlan 888
spanning-tree port type edge
```

HA packets must have the configured VLAN tag. If the switch removes or changes this tag, HA heartbeat communication will not work and network traffic will be disrupted.

HA configuration

Use the following steps to setup the configuration for HA between two FortiGate-7000s (in this example two FortiGate-7040E or 7060Es). Similar steps are required for the FortiGate-7030E except that each FortiGate-7030E only has one FIM.

Each FIM has to be configured for HA separately. The HA configuration is not synchronized among FIMs. You can begin by setting up the first FortiGate-7000 and setting up HA on both of the FIMs in it. Then do the same for the second FortiGate-7000.

To configure HA you assign a chassis ID (1 and 2) to each of the FortiGate-7000s is assigned a chassis ID.These IDs just allow you to identify the chassis and do not influence primary unit selection.

Setting up HA on the FIMs in the first FortiGate-7000 (chassis 1)

1. Log into the CLI of the FIM in slot 1 (FM01) and enter the following command:
   ```
   config system ha
      set mode a-p
      set password <password>
      set group-id <id>
      set chassis-id 1
      set hbdev M1/M2
   end
   ```
   This adds basic HA settings to this FIM.
2. Repeat this configuration on the FIM in slot 2 (FIM02).
   ```
   config system ha
      set mode a-p
      set password <password>
      set group-id <id>
      set chassis-id 1
      set hbdev M1/M2
   end
   ```
3. From either FIM, enter the following command to confirm that the FortiGate-7000 is in HA mode:
   ```
   diagnose sys ha status
   ```
   The `password` and `group-id` are unique for each HA cluster and must be the same on all FIMs. If a cluster does not form, one of the first things to check are `groupd-id` and re-enter the password on both FIMs.

Configure HA on the FIMs in the second FortiGate-7000 (chassis 2)

1. Repeat the same HA configuration settings on the FIMs in the second chassis except set the chassis ID to 2.
   ```
   config system ha
      set mode a-p
   ```

```
    set password <password>
    set group-id <id>
    set chassis-id 2
    set hbdev M1/M2
end
```

2. From any FIM, enter the following command to confirm that the cluster has formed and all of the FIMs have been added to it:

   ```
   diagnose sys ha status
   ```

   The cluster has now formed and you can add the configuration and connect network equipment and start operating the cluster. You can also modify the HA configuration depending on your requirements.

Verifying that the cluster is operating correctly

Enter the following CLI command to view the status of the cluster. You can enter this command from any module's CLI. The HA members can be in a different order depending on the module CLI from which you enter the command.

If the cluster is operating properly the following command output should indicate the primary and backup (master and slave) FortiGate-7000 as well as primary and backup (master and slave) modules. For each module, the `state` portion of the output shows all the parameters used to select the primary FIM. These parameters include the number FPMs that the FIM is connecting to that have failed, the status of any link aggregation group (LAG) interfaces in the configuration, the state of the interfaces in the FIM, the traffic bandwidth score for the FIM (the higher the traffic bandwidth score the more interfaces are connected to networks), and the status of the management links.

```
diagnose  sys  ha  status

```

Setting up HA management connections

Fortinet recommends the following configurations for redundant management connections to a FortiGate-7000 HA configuration.

- Single management connections to each of the FIMs.
- Redundant management connections to each of the FIMs.

These management connections involve connecting the static redundant management interfaces (MGMT1 to MGMT4) of each FIM in the HA configuration to one or more switches. You do not have to change the FortiGate-7000 configuration to set up redundant management connections. However, specific switch configurations are required for each of these configurations as described below.

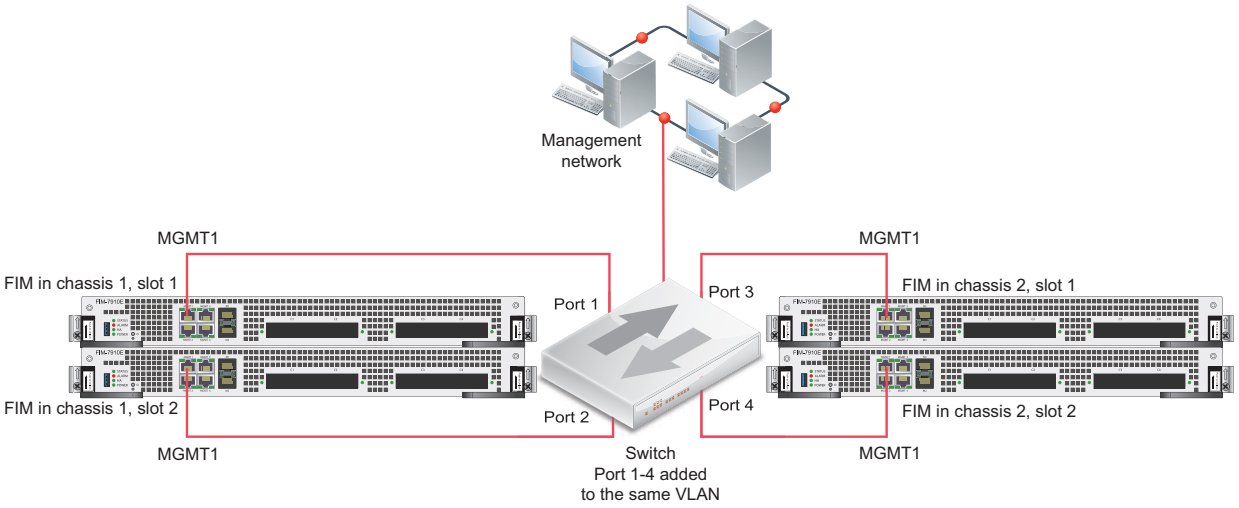
LACP is not supported for the mgmt aggregate interface.

Setting up single management connections to each of the FIMs

The simplest way to provide redundant management connections to a FortiGate-7000 HA configuration involves connecting the MGMT1 interface of each of the FIMs to four ports on a switch. On the switch you must add the four switch ports to the same VLAN. Then connect the switch to your management network and allow traffic from the VLAN to the management network.

A FortiGate-7030E HA configuration only has two FIMs so would only require two switch ports.

Example FortiGate-7000 HA redundant management connections



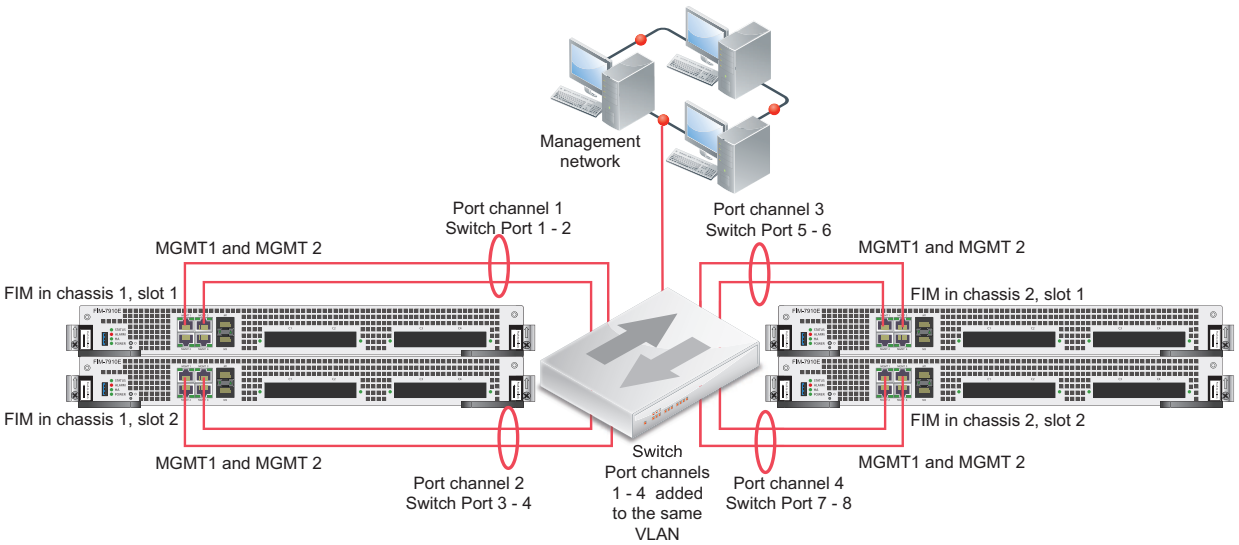
Setting up redundant management connections to each of the FIMs

You can enhance redundancy by setting up two redundant management connections to each FIM. To support this configuration, on the switch you must create a port channel for each FIM interface. Create a total of four port channels, one for each FIM and add each of the port channels to the same VLAN. Then connect the switch to your management network and allow traffic from the VLAN to the management network.

If you use two switches, the VLAN should span across both switches.

A FortiGate-7030E HA configuration only has two FIMs so would only require two port channels.

Example FortiGate-7000 HA redundant management connections with redundant connections to each FIM



Managing individual modules in HA mode

In some cases you may want to connect to an individual FIM or FPM in a specific FortiGate-7000. For example, you may want to view the traffic being processed by the FPM in slot 3 of the FortiGate-7000 designated as chassis 2. You can connect to the GUI or CLI of individual modules in the chassis using the system management IP address with a special port number.

For example, if the system management IP address is 1.1.1.1 you can browse to https://1.1.1.1:44323 to connect to the FPM in the FortiGate-7000 chassis 2 slot 3. The special port number (in this case 44323) is a combination of the service port, chassis ID, and slot number. The following table lists the special ports for common admin protocols:

FortiGate-7000 HA special administration port numbers

Chassis and Slot Number	Slot Address	HTTP (80)	HTTPS (443)	Telnet (23)	SSH (22)	SNMP (161)
Ch1 slot 5	FPM05	8005	44305	2305	2205	16105
Ch1 slot 3	FPM03	8005	44303	2303	2203	16103
Ch1 slot 1	FIM01	8003	44301	2301	2201	16101
Ch1 slot 2	FIM02	8002	44302	2302	2202	16102
Ch1 slot 4	FPM04	8004	44304	2304	2204	16104
Ch1 slot 6	FPM06	8006	44306	2306	2206	16106
Ch2 slot 5	FPM05	8005	44325	2325	2225	16125
Ch2 slot 3	FPM03	8005	44323	2323	2223	16123
Ch2 slot 1	FIM01	8003	44321	2321	2221	16121
Ch2 slot 2	FIM02	8002	44322	2322	2222	16122
Ch2 slot 4	FPM04	8004	44324	2324	2224	16124
Ch2 slot 6	FPM06	8006	44326	2326	2226	16126

For example:

- To connect to the GUI of the FPM in chassis 1 slot 3 using HTTPS you would browse to https://1.1.1.1:44313.
- To send an SNMP query to the FPM in chassis 2 slot 6 use the port number 16126.

The formula for calculating the special port number is based on Chassis ID. CH1 = Chassis ID1, CH2 = Chassis ID2. The formula is: service_port x 100 + (chassis_id – 1) x 20 + slot_id.

Upgrading FortiGate-7000 HA cluster firmware

All of the modules in your FortiGate-7000 HA configuration run the same firmware image. You upgrade the firmware from the primary FIM GUI or CLI just as you would any FortiGate product. During the upgrade process, the firmware of all of the modules in both chassis upgrades automatically in the background. Firmware upgrades should be done during a quiet time because traffic may be briefly be interrupted during the upgrade process.

Before beginning a firmware upgrade, Fortinet recommends the following:

- Review the latest release notes for the firmware version that you are upgrading to.
- Verify the recommended upgrade path as documented in the release notes.
- Backup your FortiGate-7000 HA configuration.
- Review the services provided by your FortiGate-7000 before the upgrade and then again after the upgrade to make sure everything continues to operate normally. For example, you might want to verify that you can successfully access a key server used by your organization before the upgrade and make sure after the upgrade that you can still reach the server and that performance is comparable. You could also take a snapshot of key performance indicators (number of sessions, CPU usage, and memory usage) before the upgrade and verify that you see comparable performance after the upgrade .

Enabling uninterruptable-upgrade

Fortinet recommends upgrading your FortiGate-7000 HA configuration firmware with `uninterruptable-upgrade` enabled. With `uninterruptable-upgrade` enabled, the FortiGate-7000 HA configuration goes through a multi-step process to upgrade the firmware of all components in the configuration. Since many components are involved, the entire upgrade process may take a few minutes. It all happens automatically and should cause only minor traffic disruptions. Because of the possible disruptions, you should upgrade HA cluster firmware when traffic is low or during a maintenance period.

Use the following command to enable uninterruptable-upgrade:

```
config system ha
   set uninterruptable-upgrade enable
end
```

The following steps happen in the background when upgrading the firmware running on a FortiGate-7000 HA cluster with `uninterruptable-upgrade` enabled.

- The firmware upgrade downloads to the primary (master) FortiGate-7000.
- The primary FortiGate-7000 sends a copy of the firmware upgrade file to the backup (slave) FortiGate-7000.
- The backup FortiGate-7000 upgrades its firmware, restarts, and rejoins the cluster.
- The primary FortiGate-7000 verifies that all members of the backup FortiGate-7000 can process traffic. The firmware upgrade will not proceed until all of the backup FortiGate-7000 components are operating.
- The primary FortiGate-7000 then sends a switchover command and the backup FortiGate-7000 becomes the primary FortiGate-7000.
- The new primary FortiGate-7000 sends gratuitous ARP packets to inform attached network devices to send packets to the new primary FortiGate-7000.
- Traffic switches over to the new primary FortiGate-7000.
- The original primary FortiGate-7000 upgrades its firmware, restarts, and rejoins the cluster as the backup FortiGate-7000.

The amount of time this process takes and the probability of minor traffic disruptions depends on the number of modules in your FortiGate-7000 and on traffic load conditions, the network configuration, and how quickly the gratuitous ARP packets update network devices.

Distributed clustering

FortiGate-7000 HA supports separating the FortiGate-7000s in different physical locations. Distributed FortiGate-7000 HA clustering (or geographically distributed FortiGate-7000 HA or geo clustering) can involve two FortiGate-7000s in different rooms in the same building, different buildings in the same location, or even different geographical sites such as different cities, countries or continents.

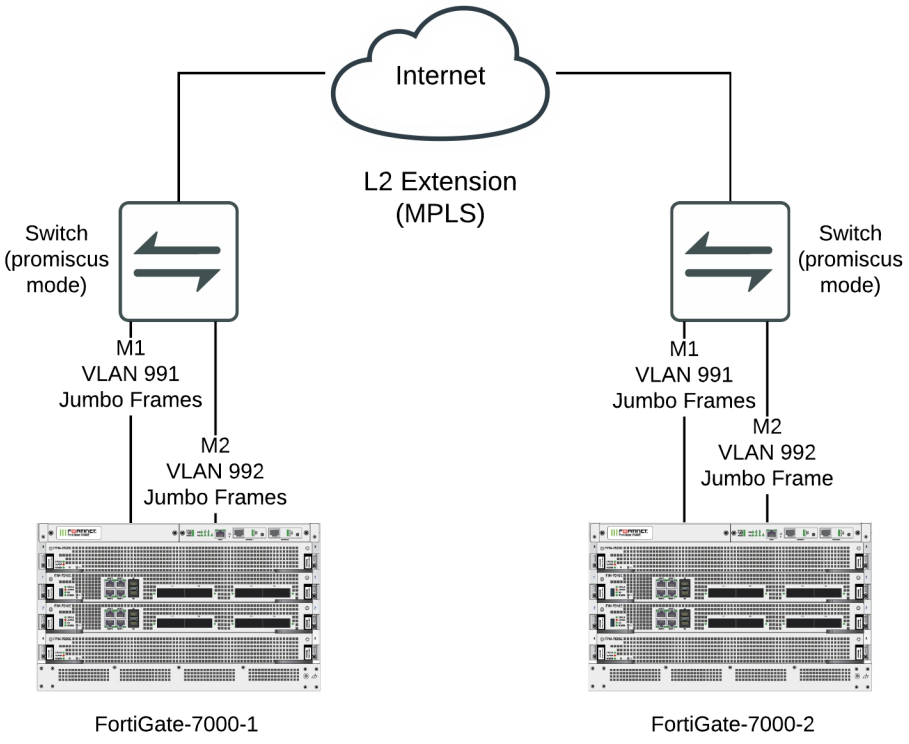
Just like any FortiGate-7000 HA configuration, distributed FortiGate-7000 HA requires heartbeat communication between the FortiGate-7000s over the M1 and M2 interfaces. In a distributed FortiGate-7000 HA configuration this heartbeat communication can take place over the Internet or over other transmission methods including satellite linkups.

Most Data Center Interconnect (DCI) or MPLS-based solutions that support layer 2 extensions and VLAN tags between the remote data centers should also support HA heartbeat communication between the FortiGates in the distributed locations. Using VLANs and switches in promiscuous mode to pass all traffic between the locations can also be helpful.

You cannot change HA heartbeat IP addresses, so the heartbeat interfaces have to be able to communication over the same subnet.

The M1 and M2 interface traffic must be separated. You can do this by using separate channels for each interface or by configuring the M1 and M2 interfaces to use different VLANs.

Example FortiGate-7000 distributed clustering configuration



Because of the possible distance between sites, it may take a relatively long time for heartbeat packets to be transmitted between the FortiGate-7000s. This could lead to a split brain scenario. To avoid a split brain scenario you can modify heartbeat timing so that the cluster expects extra time between heartbeat packets. As a general rule, set the heartbeat failover time (`hb-interval`) to be longer than the max latency or round trip time (RTT). You could also increase the `hb-lost-threshold` to tolerate losing heartbeat packets if the network connection is less reliable.

In addition you could use different link paths for heartbeat packets to optimize HA heartbeat communication. You could also configure QoS on the links used for HA heartbeat traffic to make sure heartbeat communication has the highest priority.

Modifying heartbeat timing

If the FortiGate-7000s in the HA cluster do not receive heartbeat packets on time, the FortiGate-7000s in the HA configuration may each determine that the other FortiGate-7000 has failed. HA heartbeat packets may not be sent on time because of network issues. For example, if the M1 and M2 communications links between the FortiGate-7000s become too busy to handle the heartbeat traffic. Also, in a distributed clustering configuration the round trip time (RTT) between the FortiGate-7000s may be longer the expected time between heartbeat packets.

In addition, if the FortiGate-7000s becomes excessively busy, they may delay sending heartbeat packets.

Even with these delays, the FortiGate-7000 HA cluster can continue to function normally as long as the HA heartbeat configuration supports longer delays between heartbeat packets and more missed heartbeat packets.

You can use the following commands to configure heartbeat timing:

```
config system ha
   set hb-interval <interval_integer>
   set hb-lost-threshold <threshold_integer>
   set hello-holddown <holddown_integer>
end
```

Changing the heartbeat interval

The heartbeat interval is the time between sending HA heartbeat packets. The heartbeat interval range is 1 to 20 (100*ms). The heartbeat interval default is 2 (200 ms).

A heartbeat interval of 2 means the time between heartbeat packets is 200 ms. Changing the heartbeat interval to 5 changes the time between heartbeat packets to 500 ms (5 * 100ms = 500ms).

Use the following CLI command to increase the heartbeat interval to 10:

```
config system ha
   set hb-interval 10
end
```

Changing the lost heartbeat threshold

The lost heartbeat threshold is the number of consecutive heartbeat packets that a FortiGate does not receive before assuming that a failure has occurred. The default value of 6mean that if a FortiGate-7000 does not receive 6 heartbeat packets it determines that the other FortiGate-7000 in the cluster has failed. The range is 1 to 60 packets.

The lower the `hb-lost-threshold`, the faster a FortiGate-7000 HA configuration responds when a failure occurs. However, sometimes heartbeat packets may not be received because the other FortiGate-7000 is very busy or because of network conditions. This can lead to a false positive failure detection. To reduce these false positives you can increase the `hb-lost-threshold`.

Use the following command to increase the lost heartbeat threshold to 12:

```
config system ha
   set hb-lost-threshold 12
end
```

Adjusting the heartbeat interval and lost heartbeat threshold

The heartbeat interval combines with the lost heartbeat threshold to set how long a FortiGate-7000 waits before assuming that the other FortiGate-7000 has failed and is no longer sending heartbeat packets. By default, if a FortiGate-7000 does not receive a heartbeat packet from a cluster unit for 6 * 200 = 1200 milliseconds or 1.2 seconds the FortiGate-7000 assumes that the other FortiGate-7000 has failed.

You can increase both the heartbeat interval and the lost heartbeat threshold to reduce false positives. For example, increasing the heartbeat interval to 20 and the lost heartbeat threshold to 30 means a failure will be assumed if no heartbeat packets are received after 30 * 2000 milliseconds = 60,000 milliseconds, or 60 seconds.

Use the following command to increase the heartbeat interval to 20 and the lost heartbeat threshold to 30:

```
config system ha
   set hb-lost-threshold 20
   set hb-interval 30
end
```

Changing the time to wait in the hello state

The hello state hold-down time is the number of seconds that a FortiGate-7000 waits before changing from hello state to work state. After a failure or when starting up, FortiGate-7000s in HA mode operate in the hello state to send and receive heartbeat packets to find each other and form a cluster. A FortiGate-7000 should change from the hello state to work state after it finds the FortiGate-7000 to form a cluster with. If for some reason the FortiGate-7000s cannot find each other during the hello state both FortiGate-7000s may assume that the other one has failed and each could form separate clusters of one FortiGate-7000. The FortiGate-7000s could eventually find each other and negotiate to form a cluster, possibly causing a network interruption as they re-negotiate.

One reason for a delay of the FortiGate-7000s finding each other could be the FortiGate-7000s are located at different sites or for some other reason communication is delayed between the heartbeat interfaces. If you find that your FortiGate-7000s leave the hello state before finding each other you can increase the time that they wait in the hello state. The hello state hold-down time range is 5 to 300 seconds. The hello state hold-down time default is 20 seconds.

Use the following command to increase the time to wait in the hello state to 1 minute (60 seconds):

```
config system ha
   set hello-holddown 60
end
```

Session failover (session-pickup)

Session failover means that after a failover, communications sessions resume on the new primary FortiGate-7000 with minimal or no interruption. Two categories of sessions need to be resumed after a failover:

- Sessions passing through the cluster
- Sessions terminated by the cluster

Session failover (also called session-pickup) is not enabled by default for FortiGate-7000 HA. If sessions pickup is enabled, while the FortiGate-7000 HA cluster is operating the primary FortiGate-7000 informs the backup FortiGate-7000 of changes to the primary FortiGate-7000 connection and state tables for TCP and UDP sessions passing through the cluster, keeping the backup FortiGate-7000 up-to-date with the traffic currently being processed by the cluster.

After a failover the new primary FortiGate-7000 recognizes open sessions that were being handled by the cluster. The sessions continue to be processed by the new primary FortiGate-7000 and are handled according to their last known state.

Session-pickup has some limitations. For example, session failover is not supported for sessions being scanned by proxy-based security profiles. Session failover is supported for sessions being scanned by flow-based security profiles; however, flow-based sessions that fail over are not inspected after they fail over.

Sessions terminated by the cluster include management sessions (such as HTTPS connections to the FortiGate GUI or SSH connection to the CLI as well as SNMP and logging and so on). Also included in this category are IPsec VPN, SSL VPN, sessions terminated by the cluster, and explicit proxy sessions. In general, whether or not session-pickup is enabled, these sessions do not failover and have to be restarted.

Enabling session pickup for TCP and UDP

To enable session-pickup, from the CLI enter:

```
config system ha
   set session-pickup enable
end
```

When session-pickup is enabled, sessions in the primary FortiGate-7000 TCP and UDP session tables are synchronized to the backup FortiGate-7000. As soon as a new TCP or UDP session is added to the primary FortiGate-7000 session table, that session is synchronized to the backup FortiGate-7000. This synchronization happens as quickly as possible to keep the session tables synchronized.

If the primary FortiGate-7000 fails, the new primary FortiGate-7000 uses its synchronized session tables to resume all TCP and UDP sessions that were being processed by the former primary FortiGate-7000 with only minimal interruption. Under ideal conditions all TCP and UDP sessions should be resumed. This is not guaranteed though and under less than ideal conditions some sessions may need to be restarted.

If session pickup is disabled

If you disable session pickup, the FortiGate-7000 HA cluster does not keep track of sessions and after a failover, active sessions have to be restarted or resumed. Most session can be resumed as a normal result of how TCP and UDP resumes communication after any routine network interruption.

The session-pickup setting does not affect session failover for sessions terminated by the cluster.

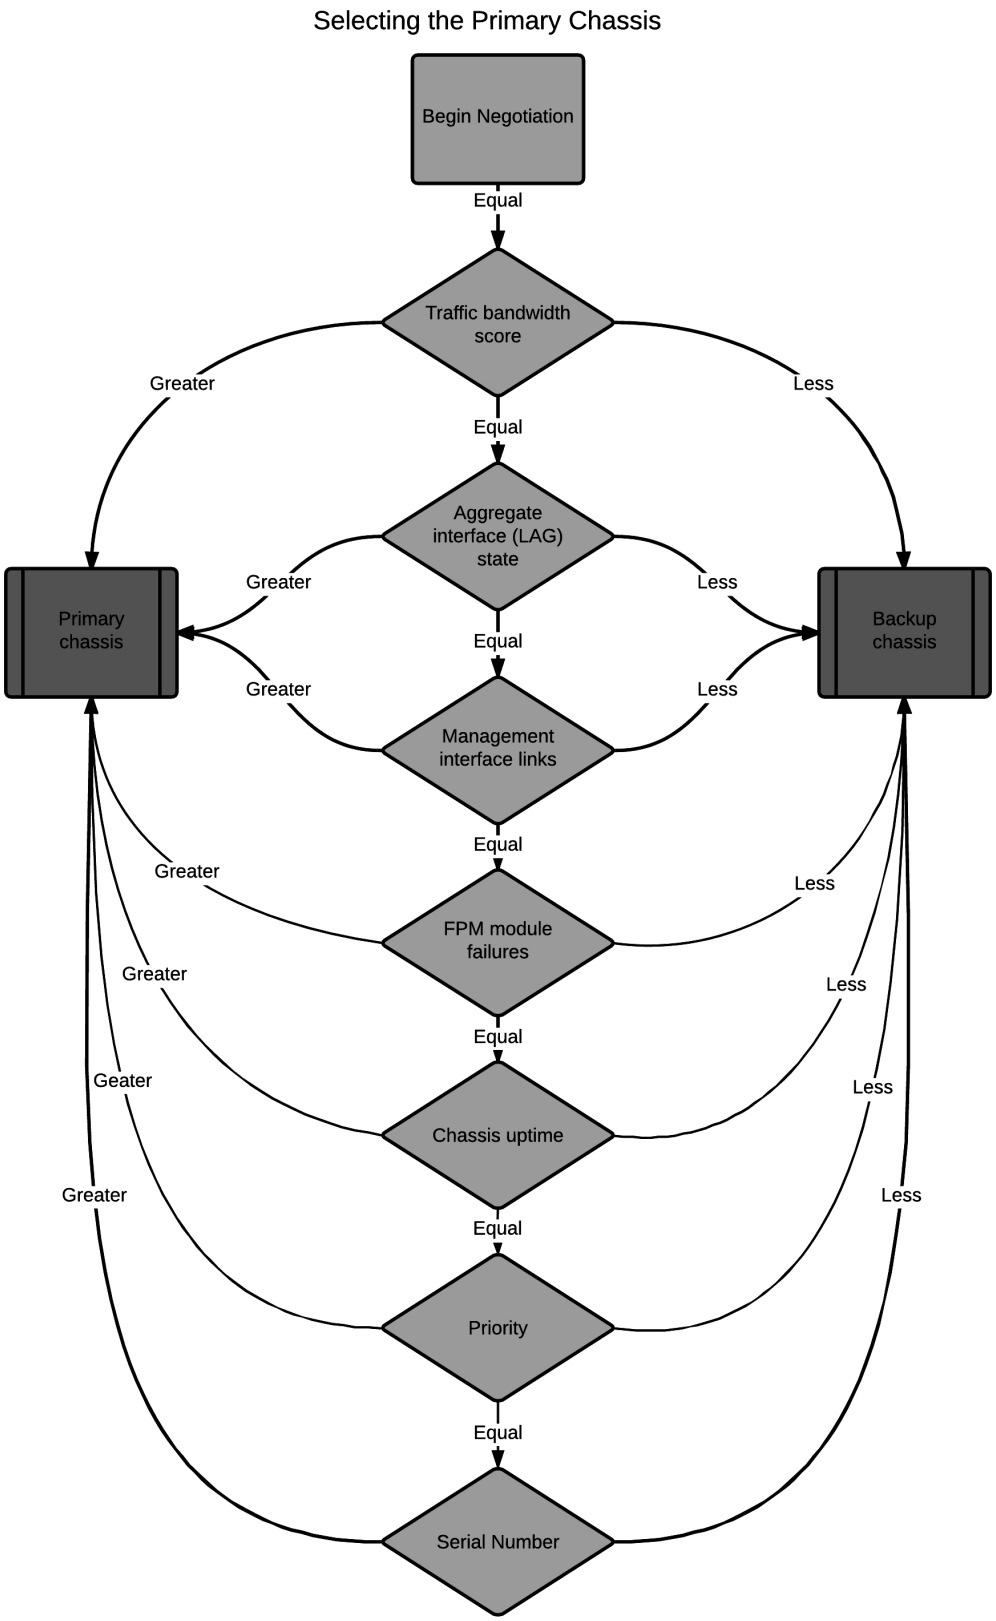
If you do not require session failover protection, leaving session pickup disabled may reduce CPU usage and reduce HA heartbeat network bandwidth usage. Also if your FortiGate-7000 HA cluster is mainly being used for

traffic that is not synchronized (for example, for proxy-based security profile processing) enabling session pickup is not recommended since most sessions will not be failed over anyway.

Primary FortiGate-7000 chassis selection and failover criteria

Once two FortiGate-7000s recognize that they can form a cluster, they negotiate to select a primary FortiGate-7000. Primary FortiGate-7000 selection occurs automatically based on the criteria shown below. After the cluster selects the primary FortiGate-7000, the other FortiGate-7000 becomes the backup.

Negotiation and primary FortiGate-7000 selection also takes place if the one of the criteria for selecting the primary chassis changes. For example, an interface can become disconnected or module can fail. After this happens, the cluster can renegotiate to select a new primary FortiGate-7000 also using the criteria shown below.



Selecting the Primary Chassis

Equal
Serial Number

If there are no failures and if you haven't configured any settings to influence primary FortiGate-7000 selection, the FortiGate-7000 with the highest serial number becomes the primary FortiGate-7000.

Using the serial number is a convenient way to differentiate FortiGate-7000s; so basing primary FortiGate-7000 selection on the serial number is predictable and easy to understand and interpret. Also the FortiGate-7000 with the highest serial number would usually be the newest with the most recent hardware version. In many cases you may not need active control over primary FortiGate-7000 selection, so basic primary FortiGate-7000 selection based on serial number is sufficient.

In some situations you may want have control over the FortiGate-7000 that becomes the primary FortiGate-7000. You can control primary FortiGate-7000 selection by setting the priority of one FortiGate-7000 to be higher than the priority of the other. If you change the priority of one of the FortiGate-7000, during negotiation, the FortiGate-7000 with the highest priority becomes the primary FortiGate-7000 . As shown above, FGCP selects the primary FortiGate-7000 based on priority before serial number. For more information about how to use priorities, see **Primary FortiGate-7000 chassis selection and failover criteria on page 861**.

FortiGate-7000 uptime is also a factor. Normally when two FortiGate-7000s start up their uptimes are similar and do not affect primary FortiGate-7000 selection. However, during operation, if one of the FortiGate-7000s goes down the other will have a much higher uptime and will be selected as the primary FortiGate-7000 before priority and serial number are tested.

Verifying primary FortiGate-7000 selection

You can use the `diagnose sys ha status` command to verify which FortiGate-7000 has become the primary FortiGate-7000 as shown by the following command output example. This output also shows that the FortiGate-7000 with the highest serial number was selected to be the primary chassis.

```
diagnose  sys  ha  status
==========================================================================
Current slot: 1  Module SN: FIM04E3E16000085
Chassis HA mode: a-p

Chassis HA information:
[Debug_Zone HA information]
HA group member information: is_manage_master=1.
FG74E83E16000015:  Slave, serialno_prio=1, usr_priority=128, hostname=CH15
FG74E83E16000016: Master, serialno_prio=0, usr_priority=127, hostname=CH16
```

How link and module failures affect primary FortiGate-7000 selection

The total number of connected data interfaces in a FortiGate-7000 has a higher priority than the number of failed modules in determining which FortiGate-7000 HA configuration has become the primary FortiGate-7000. For example, if one chassis has a failed FPM and the other has a disconnected or failed data interface, the chassis with the failed FPM becomes the primary unit.

For another example, the following `diagnose sys ha status` command shows the HA status for a cluster where one FortiGate-7000 has a disconnected or failed data interface and the other FortiGate-7000 has a failed FPM.

```
diagnose sys ha status
==========================================================================
Slot: 2 Module SN: FIM01E3E16000088
Chassis HA mode: a-p

Chassis HA information:
```

```
[Debug_Zone HA information]
HA group member information: is_manage_master=1.
FG74E33E16000027: Master, serialno_prio=0, usr_priority=128, hostname=Chassis-K
FG74E13E16000072: Slave, serialno_prio=1, usr_priority=128, hostname=Chassis-J

HA member information:
Chassis-K(FIM01E3E16000088), Slave(priority=1), uptime=2237.46, slot=2, chassis=1(1)
    slot: 2, chassis_uptime=2399.58,
    state: worker_failure=1/2, lag=(total/good/down/bad-score)=2/2/0/0,
           intf_state=(port up)=0, force-state(0:none)
           traffic-bandwidth-score=20, mgmt-link=1
    hbdevs: local_interface= 2-M1 best=yes
            local_interface= 2-M2 best=no

Chassis-J(FIM01E3E16000031), Slave(priority=2), uptime=2151.75, slot=2, chassis=2(1)
    slot: 2, chassis_uptime=2151.75,
    state: worker_failure=0/2, lag=(total/good/down/bad-score)=2/2/0/0,
           intf_state=(port up)=0, force-state(0:none)
           traffic-bandwidth-score=20, mgmt-link=1
    hbdevs: local_interface= 2-M1 last_hb_time= 2399.81 status=alive
            local_interface= 2-M2 last_hb_time= 0.00 status=dead

Chassis-J(FIM01E3E16000033), Slave(priority=3), uptime=2229.63, slot=1, chassis=2(1)
    slot: 1, chassis_uptime=2406.78,
    state: worker_failure=0/2, lag=(total/good/down/bad-score)=2/2/0/0,
           intf_state=(port up)=0, force-state(0:none)
           traffic-bandwidth-score=20, mgmt-link=1
    hbdevs: local_interface= 2-M1 last_hb_time= 2399.81 status=alive
            local_interface= 2-M2 last_hb_time= 0.00 status=dead

Chassis-K(FIM01E3E16000086), Master(priority=0), uptime=2203.30, slot=1, chassis=1(1)
    slot: 1, chassis_uptime=2203.30,
    state: worker_failure=1/2, lag=(total/good/down/bad-score)=2/2/0/0,
           intf_state=(port up)=1, force-state(0:none)
           traffic-bandwidth-score=30, mgmt-link=1
    hbdevs: local_interface= 2-M1 last_hb_time= 2399.74 status=alive
            local_interface= 2-M2 last_hb_time= 0.00 status=dead
```

This output shows that chassis 1 (hostname Chassis-K) is the primary or master FortiGate-7000. The reason for this is that chassis 1 has a total `traffic-bandwidth-score` of 30 + 20 = 50, while the total `traffic-bandwidth-score` for chassis 2 (hostname Chassis-J) is 20 + 20 = 40.

The output also shows that both FIMs in chassis 1 have detected a worker failure (`worker_failure=1/2`) while both FIMs in chassis 2 have not detected a worker failure `worker_failure=0/2`). The `intf-state=(port up)=1` field shows that FIM in slot 1 of chassis 1 has one more interface connected than the FIM in slot 1 of chassis 2. It is this extra connected interface that gives the FIM in chassis 1 slot 1 the higher traffic bandwidth score than the FIM in slot 1 of chassis 2.

One of the interfaces on the FIM in slot 1 of chassis 2 must have failed. In a normal HA configuration the FIMs in matching slots of each chassis should have redundant interface connections. So if one module has fewer connected interfaces this indicates a link failure.

FIM failures

If an FIM fails, not only will HA recognize this as a module failure it will also give the chassis with the failed FIM a much lower traffic bandwidth score. So an FIM failure would be more likely to cause an HA failover than a FPM

failover.

Also, the traffic bandwidth score for an FIM with more connected interfaces would be higher than the score for an FIM with fewer connected interfaces. So if a different FIM failed in each chassis, the chassis with the functioning FIM with the most connected data interfaces would have the highest traffic bandwidth score and would become the primary chassis.

Management link failures

Management connections to a FortiGate-7000 can affect primary chassis selection. If the management connection to one FortiGate-7000 become disconnected a failover will occur and the FortiGate-7000 that still has management connections will become the primary FortiGate-7000.

Serial Number

If there are no failures and if you haven't configured any settings to influence primary chassis selection, the chassis with the highest serial number to becomes the primary chassis.

Using the serial number is a convenient way to differentiate FortiGate-7000 chassis; so basing primary chassis selection on the serial number is predictable and easy to understand and interpret. Also the chassis with the highest serial number would usually be the newest chassis with the most recent hardware version. In many cases you may not need active control over primary chassis selection, so basic primary chassis selection based on serial number is sufficient.

In some situations you may want have control over which chassis becomes the primary chassis. You can control primary chassis selection by setting the priority of one chassis to be higher than the priority of the other. If you change the priority of one of the chassis, during negotiation, the chassis with the highest priority becomes the primary chassis. As shown above, FortiGate-7000 FGCP selects the primary chassis based on priority before serial number. For more information about how to use priorities, see **How link and module failures affect primary FortiGate-7000 selection on page 863**.

Chassis uptime is also a factor. Normally when two chassis start up their uptimes are similar and do not affect primary chassis selection. However, during operation, if one of the chassis goes down the other will have a much higher uptime and will be selected as the primary chassis before priority and serial number are tested.

Verifying primary chassis selection

You can use the `diagnose sys ha status` command to verify which chassis has become the primary chassis as shown by the following command output example. This output also shows that the chassis with the highest serial number was selected to be the primary chassis.

```
diagnose  sys  ha  status
============================================================================
Current slot: 1  Module SN: FIM04E3E16000085
Chassis HA mode: a-p

Chassis HA information:
[Debug_Zone HA information]
HA group member information: is_manage_master=1.
FG74E83E16000015:  Slave, serialno_prio=1, usr_priority=128, hostname=CH15
FG74E83E16000016: Master, serialno_prio=0, usr_priority=127, hostname=CH16
```

Link failure threshold and board failover tolerance

The default settings of the link failure threshold and the board failover tolerance result in the default link and module failure behavior. You can change these settings if you want to modify this behavior. For example, if you want a failover to occur if an FPM fails, even if an interface has failed, you can increase the board failover tolerance setting.

Link failure threshold

The link failure threshold determines how many interfaces in a link aggregation interface (LAG) can be lost before the LAG interface is considered down. The FortiGate-7000 with the most connected LAGs becomes the primary FortiGate-7000. If a LAG goes down the cluster will negotiate and may select a new primary FortiGate-7000. You can use the following command to change the link failure threshold:

```
config system ha
   set link-failure-threshold <threshold>
end
```

The threshold range is 0 to 80 and 0 is the default.

A threshold of 0 means that if a single interface in any LAG fails the LAG is considered down. A higher failure threshold means that more interfaces in a LAG can fail before the LAG is considered down. For example, if the threshold is set to 1, at least two interfaces will have to fail.

Board failover tolerance

You can use the following command to configure board failover tolerance.

```
config system ha
   set board-failover-tolerance <tolerance>
end
```

The tolerance range is 0 to 12, and 0 is the default.

A tolerance of 0 means that if a single module fails in the primary FortiGate-7000 a failover occurs and the FortiGate-7000 with the fewest failed modules becomes the new primary FortiGate-7000. A higher failover tolerance means that more modules can fail before a failover occurs. For example, if the tolerance is set to 1, at least two modules in the primary FortiGate-7000 will have to fail before a failover occurs.

Priority and primary FortiGate-7000 selection

You can select a FortiGate-7000 to become the primary FortiGate-7000 by setting the HA priority of one or more of its FIMs (for example, the FIM in slot 1) higher than the priority of the other FIMs. Enter the following command to set the HA priority:

```
config system ha
   set priority <number>
end
```

The default priority is 128.

The FortiGate-7000 with the highest total FIM priority becomes the primary FortiGate-7000.

Override and primary FortiGate-7000 selection

Enabling `override` changes the order of primary FortiGate-7000 selection. If you have enabled `override`, primary FortiGate-7000 selection considers priority before up time and serial number. This means that if you set the device priority higher for one FortiGate-7000, with `override` enabled this FortiGate-7000 becomes the primary FortiGate-7000 even if its uptime and serial number are lower than the other FortiGate-7000.

Enter the following command to enable override.

```
config system ha
   set override enable
end
```

When `override` is enabled primary FortiGate-7000 selection checks the traffic bandwidth score, aggregate interface state, management interface links and FPM failures first. Any of these factors can affect primary chassis selection, even if you have enabled override.

FortiGate-7000 v5.4.9 special features and limitations

This section describes special features and limitations for FortiGate-7000 v5.4.9.

Managing the FortiGate-7000

Management is only possible through the MGMT1 to MGMT4 front panel management interfaces. By default the MGMT1 to MGMT4 interfaces of the FIMs in slot 1 and slot 2 are in a single static aggregate interface named

mgmt with IP address 192.168.1.99. You manage the FortiGate-7000 by connecting any one of these eight interfaces to your network, opening a web browser and browsing to https://192.168.1.99.

The FortiGate-7030E has one FIM and the MGMT1 to MGMT4 interfaces of that module are the only ones in the aggregate interface.

Default management VDOM

By default the FortiGate-7000 configuration includes a management VDOM named dmgmt-vdom. For the FortiGate-7000 system to operate normally you should not change the configuration of this VDOM and this VDOM should always be the management VDOM. You should also not add or remove interfaces from this VDOM.

You have full control over the configurations of other FortiGate-7000 VDOMs.

Maximum number of LAGs

FortiGate-7000 systems support up to 16 link aggregation groups (LAGs). This includes both normal link aggregation groups and redundant interfaces and including the redundant interface that contains the M1 to M4 management interfaces.

Firewall

TCP sessions with NAT enabled that are expected to be idle for more than the distributed processing normal TCP timer (which is 3605 seconds) should only be distributed to the master FPM using a flow rule. You can configure the distributed normal TCP timer using the following command:

```
config system global
   set dp-tcp-normal-timer <timer>
end
```

UDP sessions with NAT enabled that are expected to be idle for more than the distributed processing normal UDP timer should only be distributed to the primary FPM using a flow rule.

IP multicast

IPv4 and IPv6 Multicast traffic is only sent to the primary FPM (usually the FPM in slot 3). This is controlled by the following configuration:

```
config load-balance flow-rule
   edit 18
      set status enable
      set vlan 0
      set ether-type ipv4
      set src-addr-ipv4 0.0.0.0 0.0.0.0
      set dst-addr-ipv4 224.0.0.0 240.0.0.0
      set protocol any
      set action forward
      set forward-slot master
      set priority 5
      set comment "ipv4 multicast"
   next
   edit 19
      set status enable
      set vlan 0
```

```
      set ether-type ipv6
      set src-addr-ipv6 ::/0
      set dst-addr-ipv6 ff00::/8
      set protocol any
      set action forward
      set forward-slot master
      set priority 5
      set comment "ipv6 multicast"
   end
```

High availability

Only the M1 and M2 interfaces are used for the HA heartbeat communication.

If you use the same switch for both M1 and M2, separate the M1 and M2 traffic on the switch and set the heartbeat traffic on the M1 and M2 Interfaces to have different VLAN IDs. For example, use the following command to set the heartbeat traffic on M1 to use VLAN ID 777 and the heartbeat traffic on M2 to use VLAN ID 888:

```
config system ha
   set hbdev-vlan-id 777
   set hbdev-second-vlan-id 888
end
```

If you don't set different VLAN IDs for the M1 and M2 heartbeat packets, q-in-q must be enabled on the switch.

The following FortiOS HA features are not supported or are supported differently by FortiGate-7000 v5.4.5:

- Remote IP monitoring (configured with the option `pingserver-monitor-interface` and related settings) is not supported.
- Active-active HA is not supported.
- The range for the HA `group-id` is 0 to 14.
- Failover logic for FortiGate-7000 v5.4.5 HA is not the same as FGCP for other FortiGate clusters.
- HA heartbeat configuration is specific to FortiGate-7000 systems and differs from standard HA.
- FortiGate Session Life Support Protocol (FGSP) HA (also called standalone session synchronization) is not supported.
- FortiGate-7000 HA does not support the `route-ttl`, `route-wait`, and `route-hold` options for tuning route synchronization between FortiGate-7000s.

Shelf manager module

It is not possible to access SMM CLI using Telnet or SSH. Only console access is supported using the chassis front panel console ports as described in the FortiGate-7000 system guide.

For monitoring purpose, IPMI over IP is supported on SMM Ethernet ports. See your FortiGate-7000 system guide for details.

FortiOS features not supported by FortiGate-7000 v5.4.5

The following mainstream FortiOS 5.4.5 features are not supported by the FortiGate-7000 v5.4.5:

- Hardware switch
- Switch controller
- WiFi controller
- WAN load balancing (SD-WAN)

- IPv4 over IPv6, IPv6 over IPv4, IPv6 over IPv6 features
- GRE tunneling is only supported after creating a load balance flow rule, for example:

```
config load-balance flow-rule
   edit 0
      set status enable
      set vlan 0
      set ether-type ip
      set protocol gre
      set action forward
      set forward-slot master
      set priority 3
   end
```

- Hard disk features including, WAN optimization, web caching, explicit proxy content caching, disk logging, and GUI-based packet sniffing.
- Log messages should be sent only using the management aggregate interface

IPsec VPN tunnels terminated by the FortiGate-7000

This section lists FortiGate-7000 limitations for IPsec VPN tunnels terminated by the FortiGate-7000:

- Interface-based IPsec VPN is recommended.
- Policy based IPsec VPN is supported, but requires creating flow-rules for each Phase 2 selector.
- Dynamic routing and policy routing is not supported for IPsec interfaces.
- IPsec static routes don't consider distance, weight, priority settings. IPsec static routes are always installed in the routing table, regardless of the tunnel state.
- IPsec tunnels are not load-balanced across the FPMs, all IPsec tunnel sessions are sent to the primary FPM.
- IPsec VPN dialup or dynamic tunnels require a flow rule that sends traffic destined for IPsec dialup IP pools to the primary FPM.
- In an HA configuration, IPsec SAs are not synchronized to the backup chassis. IPsec SAs are renegotiated after a failover.

SSL VPN

Sending all SSL VPN sessions to the primary FPM is recommended. You can do this by:

- Creating a flow rule that sends all sessions that use the SSL VPN destination port and IP address to the primary FPM.
- Creating flow rules that send all sessions that use the SSL VPN IP pool addresses to the primary FPM.

Traffic shaping and DDoS policies

Each FPM applies traffic shaping and DDoS quotas independently. Because of load-balancing, this may allow more traffic than expected.

Sniffer mode (one-arm sniffer)

One-arm sniffer mode is only supported after creating a load balance flow rule to direct sniffer traffic to a specific FPM.

FortiGuard web filtering

All FortiGuard rating queries are sent through management aggregate interface from the management VDOM (named dmgmt-vdom).

Log messages include a slot field

An additional "slot" field has been added to log messages to identify the FPM that generated the log.

FortiOS Carrier

You have to apply a FortiOS Carrier license separately to each FIM and FPM to license a FortiGate-7000 chassis for FortiOS Carrier.

Special notice for new deployment connectivity testing

Only the primary FPM can successfully ping external IP addresses. During a new deployment, while performing connectivity testing from the Fortigate-7000, make sure to run `execute ping` tests from the primary FPM CLI.

Dedicated management interfaces not supported

The FortiGate-7000 does not support configuring dedicated management interfaces using the `config system dedicated-mgmt` command.

FortiGate-7000 v5.4.5 special features and limitations

This section describes special features and limitations for FortiGate-7000 v5.4.5.

Managing the FortiGate-7000

Management is only possible through the MGMT1 to MGMT4 front panel management interfaces. By default the MGMT1 to MGMT4 interfaces of the FIMs in slot 1 and slot 2 are in a single static aggregate interface named mgmt with IP address 192.168.1.99. You manage the FortiGate-7000 by connecting any one of these eight interfaces to your network, opening a web browser and browsing to https://192.168.1.99.

The FortiGate-7030E has one FIM and the MGMT1 to MGMT4 interfaces of that module are the only ones in the aggregate interface.

Default management VDOM

By default the FortiGate-7000 configuration includes a management VDOM named dmgmt-vdom. For the FortiGate-7000 system to operate normally you should not change the configuration of this VDOM and this VDOM should always be the management VDOM. You should also not add or remove interfaces from this VDOM.

You have full control over the configurations of other FortiGate-7000 VDOMs.

Firewall

TCP sessions with NAT enabled that are expected to be idle for more than the distributed processing normal TCP timer (which is 3605 seconds) should only be distributed to the master FPM using a flow rule. You can configure the distributed normal TCP timer using the following command:

```
config system global
   set dp-tcp-normal-timer <timer>
end
```

UDP sessions with NAT enabled that are expected to be idle for more than the distributed processing normal UDP timer should only be distributed to the primary FPM using a flow rule.

IP multicast

IPv4 and IPv6 Multicast traffic is only sent to the primary FPM (usually the FPM in slot 3). This is controlled by the following configuration:

```
config load-balance flow-rule
   edit 18
      set status enable
      set vlan 0
      set ether-type ipv4
      set src-addr-ipv4 0.0.0.0 0.0.0.0
      set dst-addr-ipv4 224.0.0.0 240.0.0.0
      set protocol any
      set action forward
      set forward-slot master
      set priority 5
      set comment "ipv4 multicast"
```

```
next
edit 19
   set status enable
   set vlan 0
   set ether-type ipv6
   set src-addr-ipv6 ::/0
   set dst-addr-ipv6 ff00::/8
   set protocol any
   set action forward
   set forward-slot master
   set priority 5
   set comment "ipv6 multicast"
end
```

High availability

Only the M1 and M2 interfaces are used for the HA heartbeat communication.

If you use the same switch for both M1 and M2, separate the M1 and M2 traffic on the switch and set the heartbeat traffic on the M1 and M2 Interfaces to have different VLAN IDs. For example, use the following command to set the heartbeat traffic on M1 to use VLAN ID 777 and the heartbeat traffic on M2 to use VLAN ID 888:

```
config system ha
   set hbdev-vlan-id 777
   set hbdev-second-vlan-id 888
end
```

If you don't set different VLAN IDs for the M1 and M2 heartbeat packets, q-in-q must be enabled on the switch.

The following FortiOS HA features are not supported or are supported differently by FortiGate-7000 v5.4.5:

- Remote IP monitoring (configured with the option `pingserver-monitor-interface` and related settings) is not supported.
- Active-active HA is not supported.
- The range for the HA `group-id` is 0 to 14.
- Failover logic for FortiGate-7000 v5.4.5 HA is not the same as FGCP for other FortiGate clusters.
- HA heartbeat configuration is specific to FortiGate-7000 systems and differs from standard HA.
- FortiGate Session Life Support Protocol (FGSP) HA (also called standalone session synchronization) is not supported.
- FortiGate-7000 HA does not support the `route-ttl`, `route-wait`, and `route-hold` options for tuning route synchronization between FortiGate-7000s.

Shelf manager module

It is not possible to access SMM CLI using Telnet or SSH. Only console access is supported using the chassis front panel console ports as described in the FortiGate-7000 system guide.

For monitoring purpose, IPMI over IP is supported on SMM Ethernet ports. See your FortiGate-7000 system guide for details.

FortiOS features not supported by FortiGate-7000 v5.4.5

The following mainstream FortiOS 5.4.5 features are not supported by the FortiGate-7000 v5.4.5:

- Hardware switch
- Switch controller
- WiFi controller
- WAN load balancing (SD-WAN)
- IPv4 over IPv6, IPv6 over IPv4, IPv6 over IPv6 features
- GRE tunneling is only supported after creating a load balance flow rule, for example:

```
config load-balance flow-rule
   edit 0
      set status enable
      set vlan 0
      set ether-type ip
      set protocol gre
      set action forward
      set forward-slot master
      set priority 3
   end
```

- Hard disk features including, WAN optimization, web caching, explicit proxy content caching, disk logging, and GUI-based packet sniffing.
- Log messages should be sent only using the management aggregate interface

IPsec VPN tunnels terminated by the FortiGate-7000

This section lists FortiGate-7000 limitations for IPsec VPN tunnels terminated by the FortiGate-7000:

- Interface-based IPsec VPN is recommended.
- Policy based IPsec VPN is supported, but requires creating flow-rules for each Phase 2 selector.
- Dynamic routing and policy routing is not supported for IPsec interfaces.
- IPsec static routes don't consider distance, weight, priority settings. IPsec static routes are always installed in the routing table, regardless of the tunnel state.
- IPsec tunnels are not load-balanced across the FPMs, all IPsec tunnel sessions are sent to the primary FPM.
- IPsec VPN dialup or dynamic tunnels require a flow rule that sends traffic destined for IPsec dialup IP pools to the primary FPM.
- In an HA configuration, IPsec SAs are not synchronized to the backup chassis. IPsec SAs are renegotiated after a failover.

SSL VPN

Sending all SSL VPN sessions to the primary FPM is recommended. You can do this by:

- Creating a flow rule that sends all sessions that use the SSL VPN destination port and IP address to the primary FPM.
- Creating flow rules that send all sessions that use the SSL VPN IP pool addresses to the primary FPM.

Traffic shaping and DDoS policies

Each FPM applies traffic shaping and DDoS quotas independently. Because of load-balancing, this may allow more traffic than expected.

Sniffer mode (one-arm sniffer)

One-arm sniffer mode is only supported after creating a load balance flow rule to direct sniffer traffic to a specific FPM.

FortiGuard web filtering

All FortiGuard rating queries are sent through management aggregate interface from the management VDOM (named dmgmt-vdom).

Log messages include a slot field

An additional "slot" field has been added to log messages to identify the FPM that generated the log.

FortiOS Carrier

You have to apply a FortiOS Carrier license separately to each FIM and FPM to license a FortiGate-7000 chassis for FortiOS Carrier.

Special notice for new deployment connectivity testing

Only the primary FPM can successfully ping external IP addresses. During a new deployment, while performing connectivity testing from the Fortigate-7000, make sure to run `execute ping` tests from the primary FPM CLI.

Dedicated management interfaces not supported

The FortiGate-7000 does not support configuring dedicated management interfaces using the `config system dedicated-mgmt` command.

FortiGate-7000 v5.4.3 special features and limitations

This section describes special features and limitations for FortiGate-7000 v5.4.3.

Managing the FortiGate-7000

Management is only possible through the MGMT1 to MGMT4 front panel management interfaces. By default the MGMT1 to MGMT4 interfaces of the FIMs in slot 1 and slot 2 are in a single static aggregate interface named mgmt with IP address 192.168.1.99. You manage the FortiGate-7000 by connecting any one of these eight interfaces to your network, opening a web browser and browsing to https://192.168.1.99.

The FortiGate-7030E has one FIM and the MGMT1 to MGMT4 interfaces of that module are the only ones in the aggregate interface.

Default management VDOM

By default the FortiGate-7000 configuration includes a management VDOM named dmgmt-vdom. For the FortiGate-7000 system to operate normally you should not change the configuration of this VDOM and this VDOM should always be the management VDOM. You should also not add or remove interfaces from this VDOM.

You have full control over the configurations of other FortiGate-7000 VDOMs.

Firewall

TCP sessions with NAT enabled that are expected to be idle for more than the distributed processing normal TCP timer (which is 3605 seconds) should only be distributed to the master FPM using a flow rule. You can configure the distributed normal TCP timer using the following command:

```
config system global
   set dp-tcp-normal-timer <timer>
end
```

UDP sessions with NAT enabled that are expected to be idle for more than the distributed processing normal UDP timer should only be distributed to the primary FPM using a flow rule.

Link monitoring and health checking

ICMP-based link monitoring for SD-WAN, ECMP, HA link monitoring, and firewall session load balancing monitoring (or health checking) is not supported. Using TCP or UDP options for link monitoring instead.

IP multicast

IPv4 and IPv6 Multicast traffic is only sent to the primary FPM (usually the FPM in slot 3). This is controlled by the following configuration:

```
config load-balance flow-rule
   edit 18
      set status enable
      set vlan 0
      set ether-type ipv4
      set src-addr-ipv4 0.0.0.0 0.0.0.0
      set dst-addr-ipv4 224.0.0.0 240.0.0.0
```

```
      set protocol any
      set action forward
      set forward-slot master
      set priority 5
      set comment "ipv4 multicast"
   next
   edit 19
      set status enable
      set vlan 0
      set ether-type ipv6
      set src-addr-ipv6 ::/0
      set dst-addr-ipv6 ff00::/8
      set protocol any
      set action forward
      set forward-slot master
      set priority 5
      set comment "ipv6 multicast"
   end
```

High availability

Only the M1 and M2 interfaces are used for the HA heartbeat communication.

When using both M1 and M2 for the heartbeat, FortiGate-7000 v5.4.3 requires two switches. The first switch to connect all M1 ports together. The second switch to connect all M2 ports together. This is because the same VLAN is used for both M1 and M2 and the interface groups should remain in different broadcast domains.

Using a single switch for both M1 and M2 heartbeat traffic is possible if the switch supports q-in-q tunneling. In this case use different VLANs for M1 traffic and M2 traffic to keep two separated broadcast domains in the switch.

The following FortiOS HA features are not supported or are supported differently by FortiGate-7000 v5.4.3:

- Remote IP monitoring (configured with the option `pingserver-monitor-interface` and related settings) is not supported
- Active-active HA is not supported
- The range for the HA `group-id` is 0 to 14.
- Failover logic for FortiGate-7000 v5.4.3 HA is not the same as FGCP for other FortiGate clusters.
- HA heartbeat configuration is specific to FortiGate-7000 systems and differs from standard HA.
- FortiGate Session Life Support Protocol (FGSP) HA (also called standalone session synchronization) is not supported.

Shelf manager module

It is not possible to access SMM CLI using Telnet or SSH. Only console access is supported using the chassis front panel console ports as described in the FortiGate-7000 system guide.

For monitoring purpose, IPMI over IP is supported on SMM Ethernet ports. See your FortiGate-7000 system guide for details.

FortiOS features not supported by FortiGate-7000 v5.4.3

The following mainstream FortiOS 5.4.3 features are not supported by the FortiGate-7000 v5.4.3:

- Hardware switch
- Switch controller

- WiFi controller
- WAN load balancing (SD-WAN)
- IPv4 over IPv6, IPv6 over IPv4, IPv6 over IPv6 features
- GRE tunneling is only supported after creating a load balance flow rule, for example:

```
config load-balance flow-rule
   edit 0
      set status enable
      set vlan 0
      set ether-type ip
      set protocol gre
      set action forward
      set forward-slot master
      set priority 3
   end
```

- Hard disk features including, WAN optimization, web caching, explicit proxy content caching, disk logging, and GUI-based packet sniffing.
- Log messages should be sent only using the management aggregate interface

IPsec VPN tunnels terminated by the FortiGate-7000

This section lists FortiGate-7000 limitations for IPsec VPN tunnels terminated by the FortiGate-7000:

- Interface-based IPsec VPN is recommended.
- Policy based IPsec VPN is supported, but requires creating flow-rules for each Phase 2 selector.
- Dynamic routing and policy routing is not supported for IPsec interfaces.
- Remote network subnets are limited to /16 prefix.
- IPsec static routes don't consider distance, weight, priority settings. IPsec static routes are always installed in the routing table, regardless of the tunnel state.
- IPsec tunnels are not load-balanced across the FPMs, all IPsec tunnel sessions are sent to the primary FPM.
- IPsec VPN dialup or dynamic tunnels require a flow rule that sends traffic destined for IPsec dialup IP pools to the primary FPM.
- In an HA configuration, IPsec SAs are not synchronized to the backup chassis. IPsec SAs are renegotiated after a failover.

More about IPsec VPN routing limitations

For IPv4 traffic, FortiGate-7000s can only recognize netmasks with 16-bit or 32-bit netmasks. For example:

The following netmasks are supported:

- 12.34.0.0/24
- 12.34.0.0 255.255.0.0
- 12.34.56.0/21
- 12.34.56.0 255.255.248.0
- 12.34.56.78/32
- 12.34.56.78 255.255.255.255
- 12.34.56.78 (for single IP addresses, FortiOS automatically uses 32-bit netmasks)

The following netmasks are not supported:

- 12.34.0.0/15 (netmask is less than 16-bit)
- 12.34.0.0 255.254.0.0 (netmask is less than 16-bit)
- 12.34.56.1-12.34.56.100 (ip range is not supported)
- 12.34.56.78 255.255.220.0 (invalid netmask)

SSL VPN

Sending all SSL VPN sessions to the primary FPM is recommended. You can do this by:

- Creating a flow rule that sends all sessions that use the SSL VPN destination port and IP address to the primary FPM.
- Creating flow rules that send all sessions that use the SSL VPN IP pool addresses to the primary FPM.

Authentication

This section lists FortiGate-7000 authentication limitations:

- Active authentication that requires a user to manually log into the FortiGate firewall can be problematic because the user may be prompted for credentials more than once as sessions are distributed to different FPMs. You can avoid this by changing the load distribution method to `src-ip`.
- FSSO is supported. Each FPM independently queries the server for user credentials.
- RSSO is only supported after creating a load balance flow rule to broadcast RADIUS accounting messages to all FPMs.

Traffic shaping and DDoS policies

Each FPM applies traffic shaping and DDoS quotas independently. Because of load-balancing, this may allow more traffic than expected.

Sniffer mode (one-arm sniffer)

One-arm sniffer mode is only supported after creating a load balance flow rule to direct sniffer traffic to a specific FPM.

FortiGuard Web Filtering

All FortiGuard rating queries are sent through management aggregate interface from the management VDOM (named dmgmt-vdom).

Log messages include a slot field

An additional "slot" field has been added to log messages to identify the FPM that generated the log.

FortiOS Carrier

FortiOS Carrier is supported by the FortiGate-7000 v5.4.3 but GTP load balancing is not supported.

You have to apply a FortiOS Carrier license separately to each FIM and FPM to license a FortiGate-7000 chassis for FortiOS Carrier.

Special notice for new deployment connectivity testing

Only the primary FPM can successfully ping external IP addresses. During a new deployment, while performing connectivity testing from the Fortigate-7000, make sure to run `execute ping` tests from the primary FPM CLI.

Dedicated management interfaces not supported

The FortiGate-7000 does not support configuring dedicated management interfaces using the `config system dedicated-mgmt` command.

FortiGate-7000 Load balancing commands

The most notable difference between a FortiGate-7000 and other FortiGates are the commands described in this section for configuring load balancing. The following commands are available:

```
config load-balance flow-rule
config load-balance setting
```

In most cases you do not have to use these commands. However, they are available to customize some aspects of load balancing.

FortiGate-6000 and FortiGate-7000 have the commands described in this chapter in common. Some of the options described in this section may not apply in the same way on these two platforms. These differences are noted in the descriptions. For example, the generic term "worker" maps to an FPC in a FortiGate-6000 and an FPM in a FortiGate-7000.

config load-balance flow-rule

Use this command to add FortiGate-6000 or FortiGate-7000 flow rules that add exceptions to how matched traffic is processed. Specifically you can use these rules to match a type of traffic and control whether the traffic is forwarded or blocked. And if the traffic is forwarded you can specify whether to forward the traffic to a specific slot or slots. Unlike firewall policies, load-balance rules are not stateful so for bi-directional traffic, you may need to define two flow rules to match both traffic directions (forward and reverse).

Syntax

```
config load-balance flow-rule
   edit 0
      set status {disable | enable}
      set src-interface <interface-name> [<interface-name>...]
      set vlan <vlan-id>
      set ether-type {any | arp | ip | ipv4 | ipv6}
      set src-addr-ipv4 <ip4-address> <netmask>
      set dst-addr-ipv4 <ip4-address> <netmask>
      set src-addr-ipv6 <ip6-address> <netmask>
      set dst-addr-ipv6 <ip6-address> <netmask>
      set protocol {any | icmp | icmpv6 | tcp | udp | igmp | sctp | gre | esp | ah | ospf
          | pim | vrrp}
      set src-l4port <start>[-<end>]
      set dst-l4port <start>[-<end>]
      set tcp-flag
      set action {forward | mirror-ingress stats | drop}
      set mirror-interface <interface-name>
      set forward-slot {master | all | load-balance | <FPM# or FPC#>}
      set priority <number>
      set comment <text>
   end
```

status {disable | enable}

Enable or disable this flow rule. Default for a new flow-rule is disable.

src-interface <interface-name> [interface-name>...}

The names of one or more FIM interface front panel interfaces accepting the traffic to be subject to the flow rule.

vlan <vlan-id>

If the traffic matching the rule is VLAN traffic, enter the VLAN ID used by the traffic.

ether-type {any | arp | ip | ipv4 | ipv6}

The type of traffic to be matched by the rule. You can match any traffic (the default) or just match ARP, IP, or IPv4 traffic.

{src-addr-ipv4 | dst-addr-ipv4} <ipv4-address> <netmask>

The source and destination address of the traffic to be matched. The default of `0.0.0.0 0.0.0.0` matches all traffic. Available if `ether-type` is set to `ipv4`.

{src-addr-ipv6 | dst-addr-ipv6} <ip-address> <netmask>

The source and destination address of the traffic to be matched. The default of `::/0` matches all traffic. Available if `ether-type` is set to `ipv6`.

protocol {any | icmp | tcp | udp | igmp | sctp | gre | esp | ah | ospf | pim | vrrp}

If `ether-type` is set to `ip`, `ipv4`, or `ipv6`, specify the protocol of the IP, IPv4, or IPv6 traffic to match the rule. The default is `any`.

{src-l4port | dst-l4port} <start>[-<end>]

Specify a source port range and a destination port range. This option appears for some protocol settings. For example if protocol is set to tcp or udp. The default range is 0-0.

action {forward | mirror-ingress | stats | drop}

How to handle matching packets. They can be dropped, forwarded to another destination or you can record statistics about the traffic for later analysis. You can combine two or three settings in one command for example, you can set `action` to both `forward` and `stats` to forward traffic and collect statistics about it. Use `append` to add multiple options.

The default action is `forward`.

The `mirror-ingress` option copies (mirrors) all ingress packets that match this flow rule and sends them to the interface specified with the `mirror-interface` option.

set mirror-interface <interface-name>

The name of the interface to send packets matched by this flow-rule when `action` is set to `mirror-ingress` or `mirror-egress`.

forward-slot {master | all | load-balance | <FPC#>}

The slot that you want to forward the traffic that matches this rule to.

`master` forwards the primary FPM or FPC.

`all` means forward the traffic to all slots.

`load-balance` means use the default load balancing configuration to handle this traffic.

`<FPM# or FPC#>` allows you to forward the matching traffic to a specific FPC (FortiGate-6000) or FPM module (FortiGate-7000). For example, FPC3 is the FortiGate-6000 FPC in slot 3. FPM3 is the FortiGate-7000 FPM module in slot 3.

priority <number>

Set the priority of the flow rule in the range 1 (highest priority) to 10 (lowest priority). Higher priority rules are matched first. You can use the priority to control which rule is matched first if you have overlapping rules.

comment <text>

Optionally add a comment that describes the rule.

config load-balance setting

Use this command to set a wide range of load balancing settings.

```
config load-balance setting
   set slbc-mgmt-intf {mgmt1 | mgmt2 | mgmt3}
   set max-miss-heartbeats <heartbeats>
   set max-miss-mgmt-heartbeats <heartbeats>
   set weighted-load-balance {disable | enable}
   set ipsec-load-balance {disable | enable}
   set gtp-load-balance {disable | enable}
   set dp-load-distribution-method {to-master | src-ip | dst-ip | src-dst-ip | src-ip-
       sport | dst-ip-dport | src-dst-ip-sport-dport}
      config workers
        edit 3
           set status enable
           set weight 5
        end
end
```

slbc-mgmt-intf {mgmt1 | mgmt2 | mgmt3}

Select the interface used for management connections. The name depends on the available management interfaces on the device you are managing. You can use this option to enable access to the FPCs directly using the special administration ports as described in Managing individual FPCs on page 759.

max-miss-heartbeats <heartbeats>

Set the number of missed heartbeats before a worker (an FPC or FPM module) is considered to have failed. If this many heartbeats are not received from a worker, this indicates that the worker is not able to process data traffic and no more traffic will be sent to this worker.

The time between heartbeats is 0.2 seconds. Range is 3 to 300. 3 means 0.6 seconds, 10 (the default) means 2 seconds, and 300 means 60 seconds.

max-miss-mgmt-heartbeats <heartbeats>

Set the number of missed management heartbeats before a worker (an FPC or FPM module) is considering to have failed. If this happens, there is a communication problem between a worker and other workers. This communication problem means the worker may not be able to synchronize configuration changes, sessions, the kernel routing table, the bridge table and so on with other workers. If a management heartbeat failure occurs, no traffic will be sent to the worker.

The time between management heartbeats is 1 second. Range is 3 to 300 seconds. The default is 20 seconds.

weighted-load-balance {disable | enable}

Enable weighted load balancing depending on the slot (or worker) weight. Use the `config workers` command to set the weight for each slot or worker.

gtp-load-balance {disable | enable}

Enable GTP load balancing. If GTP load balancing is enabled, Tunnel Endpoint Identifiers (TEIDs) are used to identify GTP sessions.

dp-load-distribution-method {to-master | round-robin | src-ip | dst-ip | src-dst-ip | src-ip-sport | dst-ip-dport | src-dst-ip-sport-dport}

Set the method used to distribute sessions among workers (FPCs or FPM modules). Usually you would only need to change the method if you had specific requirements or you found that the default method wasn't distributing sessions in the manner that you would prefer. The default is `src-dst-ip-sport-dport` which means sessions are identified by their source address and port and destination address and port.

`to-master` directs all session to the primary FPC. This method is for troubleshooting only and should not be used for normal operation. Directing all sessions to the primary FPC will have a negative impact on performance.

`src-ip` sessions are distributed across all FPCs according to their source IP address.

`dst-ip` sessions are statically distributed across all FPCs according to their destination IP address.

`src-dst-ip` sessions are distributed across all FPCs according to their source and destination IP addresses.

`src-ip-sport` sessions are distributed across all FPCs according to their source IP address and source port.

`dst-ip-dport` sessions are distributed across all FPCs according to their destination IP address and destination port.

`src-dst-ipsport-dport` sessions are distributed across all FPCs according to their source and destination IP address, source port, and destination port. This is the default load balance algorithm and represents true session-aware load balancing. All session information is taken into account when deciding where to send new sessions and where to send additional packets that are part of an already established session.

The `src-ip` and `dst-ip` load balancing methods use layer 3 information (IP addresses) to identify and load balance sessions. All of the other load balancing methods (except for `to-master`) use both layer 3 and layer 4 information (IP addresses and port numbers) to identify a TCP and UDP session. The layer 3 and layer 4 load balancing methods only use layer 3 information for other types of traffic (SCTP, ICMP, and ESP). If GTP load balancing is enabled, Tunnel Endpoint Identifiers (TEIDs) are used to identify GTP sessions.

config workers

Set the weight and enable or disable each worker (FPC or FPM module). Use the edit command to specify the slot the worker is installed in. You can enable or disable each worker and set each worker's weight.

The weight range is 1 to 10. 5 is average, 1 is -80% of average and 10 is +100% of average. The weights take effect if `weighted-loadbalance` is enabled.

```
config workers
   edit 3
      set status enable
      set weight 5
   end
```

Chapter 8 - FortiOS Carrier

This FortiOS Handbook chapter contains the following sections:

Overview of FortiOS Carrier features provides an overview of the three major topics for FortiOS Carrier — Dynamic Profiles, MMS, and GTP.

Carrier web-based manager settings describes the web-based manager interface of FortiOS Carrier specific features.

MMS Security features describes FortiOS security features as they apply to MMS including MMS virus scanning, MMS file filtering, MMS content-based Antispam protection, and MMS DLP archiving.

Message flood protection describes setting thresholds to protect your MMS servers from receiving too many messages from the same sender.

Duplicate message protection describes setting thresholds to protect your MMS servers from receiving the same message from more than one sender.

Configuring GTP on FortiOS Carrier explains configuration of the more basic FortiOS Carrier GTP features.

GTP message type filtering explains this feature, and how to configure it on FortiOS Carrier.

GTP identity filtering explains this feature, and how to configure it on FortiOS Carrier.

Troubleshooting provides answer to common FortiOS Carrier GTP issues.

Overview of FortiOS Carrier features

FortiOS Carrier specific features include Multimedia messaging service (MMS) protection, and GPRS Tunneling Protocol (GTP) protection.

All FortiGate units, carrier-enabled or not, are capable of handling Stream Control Transmission Protocol (SCTP) traffic, which is a protocol designed for and primarily used in Carrier networks.

This section includes:

Overview

FortiOS Carrier provides all the features found on FortiGate units plus added features specific to carrier networks: MMS and GTP.

MMS

MMS is a standard for sending messages that include multimedia content between mobile phones. MMS is also popular as a method of delivering news and entertainment content including videos, pictures, and text. Carrier networks include four different MMS types of messages — MM1, MM3, MM4, and MM7. See "MMS background".

GTP

The GPRS Tunneling Protocol (GTP) runs on GPRS carrier networks. GPRS is a GSM packet radio standard. It provides more efficient usage of the radio interface so that mobile devices can share the same radio channel. FortiOS supports GTPv1 and GTPv2.

GPRS provides direct connections to the Internet (TCP/IP) and X.25 networks for point-to-point services (connection-less/connection oriented) and point-to-multipoint services (broadcast).

GPRS currently supports data rates from 9.6 kbps to more than 100 kbps, and it is best suited for burst forms of traffic. GPRS involves both radio and wired components. The mobile phone sends the message to a base station unit (radio based) that converts the message from radio to wired, and sends the message to the carrier network and eventually the Internet (wired carrier network). See GTP basic concepts.

Registering FortiOS Carrier

A license is purchased from Fortinet, and is delivered by mail as a scratch card. The contained registration code is entered into the CLI according to the instructions on the card. The FortiGate unit will then factory reset itself into Carrier mode.

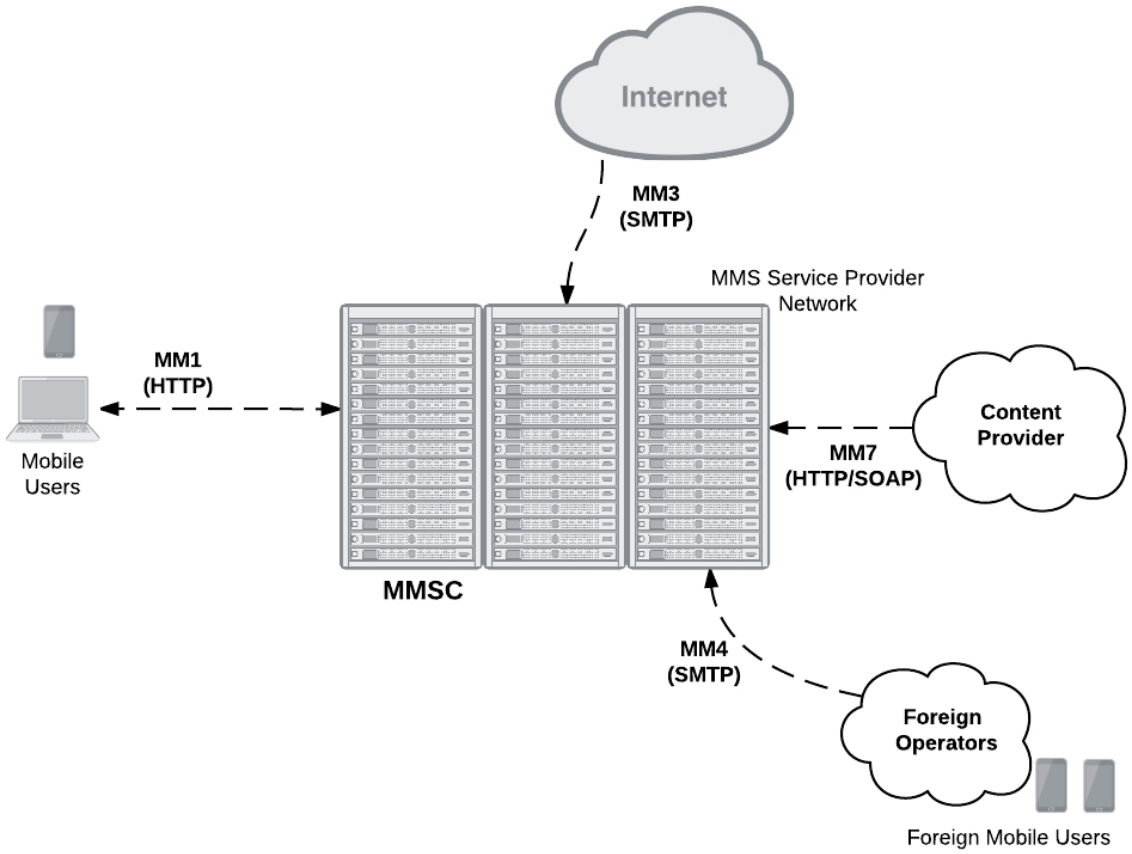
Only certain FortiGate models support Carrier mode. Contact Fortinet Support for more information and firmware images.

MMS background

MMS is a common method for mobile users to send and receive multimedia content. A Carrier network supports MMS across its network. This makes up the MMS Service Provider Network (MSPN).

Messages can be sent or received between the MMSC and a number of other services including the Internet, content providers, or other carriers. Each of these different service connections uses different MMS formats including MM1 and MM7 messages (essentially HTTP format), and MM3 and MM4 messages (SMTP formatted). These different formats reflect the different purposes and content for each type of MMS message.

MMS content interfaces



MMS content interfaces

MMS messages are sent from devices and servers to other devices and servers using MMS content interfaces

There are eight interfaces defined for the MMS standard, referred to as MM1 through MM8. The most important of these interfaces for the transfer of data is the MM1 interface, as this defines how mobile users communicate from the mobile network to the Multimedia Message Service Center (MMSC). MMS content to be monitored and controlled comes from these mobile users and is going to the provider network.

Other MMS content interfaces that connect a service provider network to other external sources can pose threats as well. MM3 handles communication between the Internet and the MMSC and is a possible source of viruses and other content problems from the Internet. MM4 handles communication between different content provider MMSCs. Filtering MM4 content protects the service provider network from content sent from foriegn service providers and their subscribers. Finally MM7 is used for communication between content providers and the MMSC. Filtering MM3 content can also keep harmful content off of the service provider network.

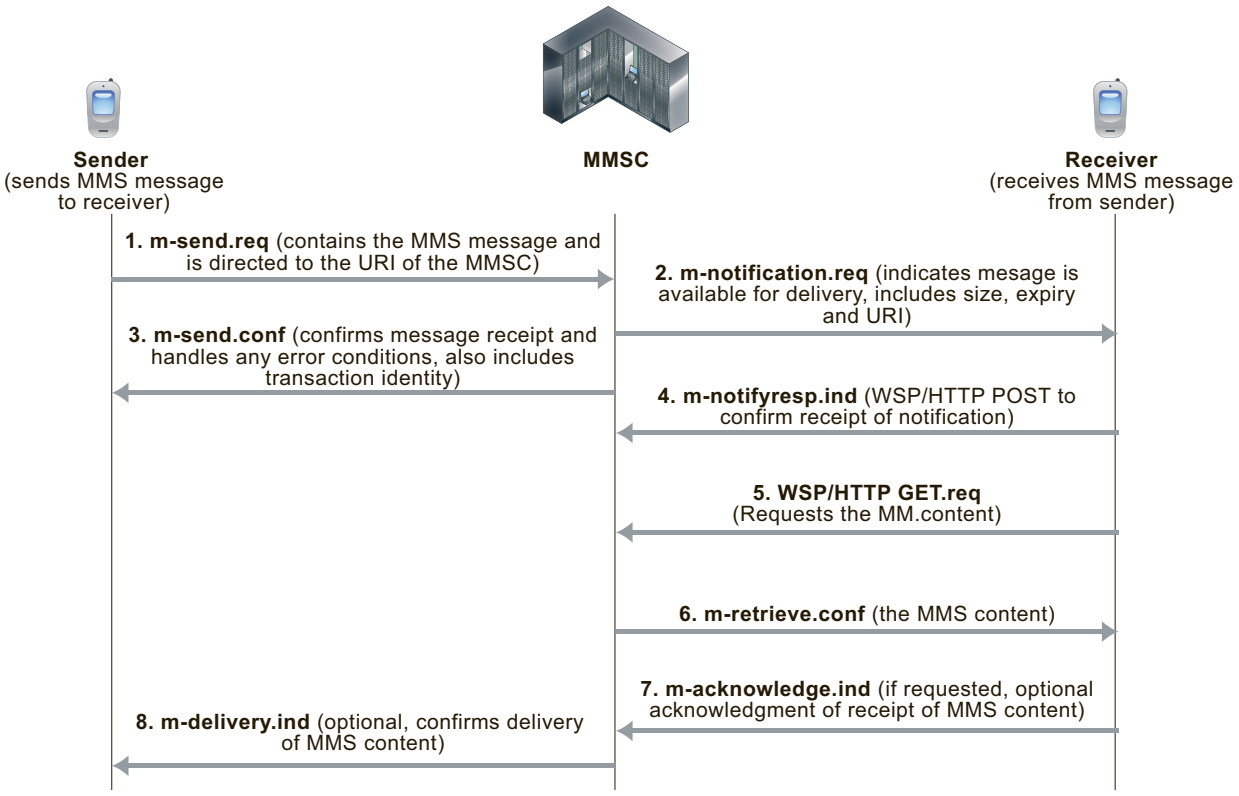
MMS content interfaces

Type	Transaction	Similar to
MM 1	Handset to MMSC	HTTP
MM 3	Between MMSC and Internet	SMTP
MM 4	Between Operator MMSCs	SMTP
MM 7	Content Providers to MMSC	HTTP and SOAP

How MMS content interfaces are applied

As shownbelow, the sender's mobile device encodes the MMS content in a form similar to MIME email message (MMS MIME content formats are defined by the MMS Message Encapsulation specification). The encoded message is then forwarded to the service provider's MMSC. Communication between the sending device and the MMSC uses the MM1 content interface. The MM1 content interface establishes a connection and sends an MM1 send request (`m-send.req`) message that contains the MMS message. The MMSC processes this request and sends back an MM1 send confirmation (`m-send.conf`) HTTP response indicating the status of the message — accepted or an error occurred, for example.

MM1 transactions between senders and receivers and the MMSC

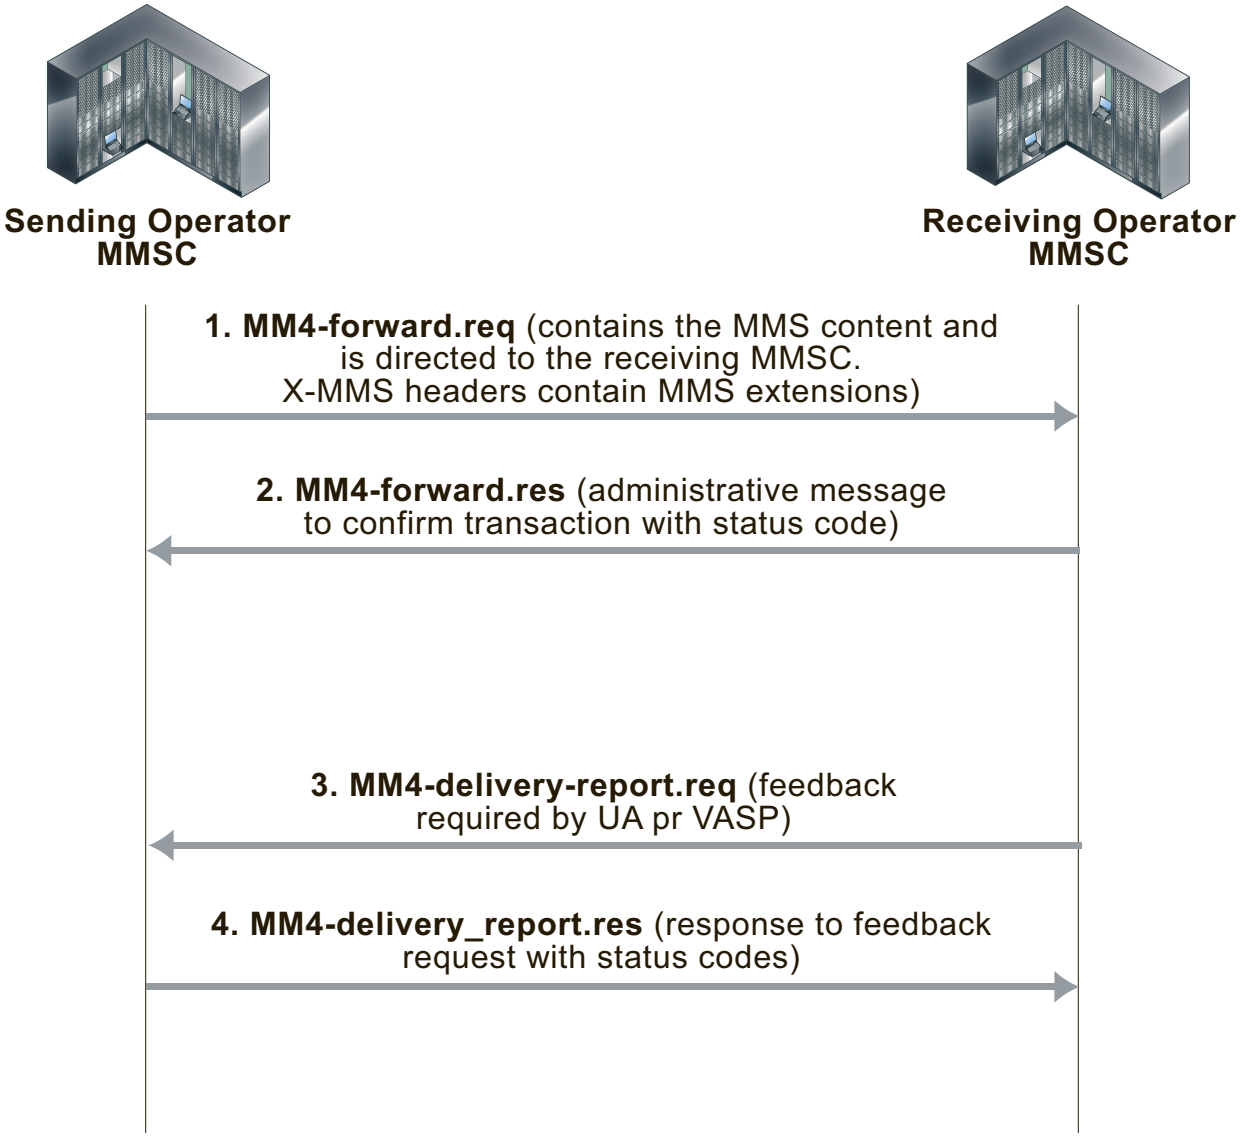


If the recipient is on another carrier, the MMSC forwards the message to the recipient's carrier. This forwarding uses the MM4 content interface for forwarding content between operator MMSCs (see the figure below).

Before the MMSC can forward the message to the final recipient, it must first determine if the receiver's handset can receive MMS messages using the MM1 content interface. If the recipient can use the MM1 content interface, the content is extracted and sent to a temporary storage server with an HTTP front-end.

To retrieve the message, the receiver's handset establishes a connection with the MMSC. An HTTP get request is then sent from the recipient to the MMSC. This message contains the URL where the content of the message is stored. The MMSC responds with a retrieve confirmation (`m-retrieve.conf`) HTTP response that contains the message.

MM4 messages sent between operator MMSCs



This causes the receiver's handset to retrieve the content from the embedded URL. Several messages are exchanged to indicate status of the delivery attempt. Before delivering content, some MMSCs also include a

content adaptation service that attempts to modify the multimedia content into a format suitable for the recipient's handset.

If the receiver's handset is not MM1 capable, the message can be delivered to a web based service and the receiver can view the content from a normal Internet browser. The URL for the content can be sent to the receiver in an SMS text message. Using this method, non-MM1 capable recipients can still receive MMS content.

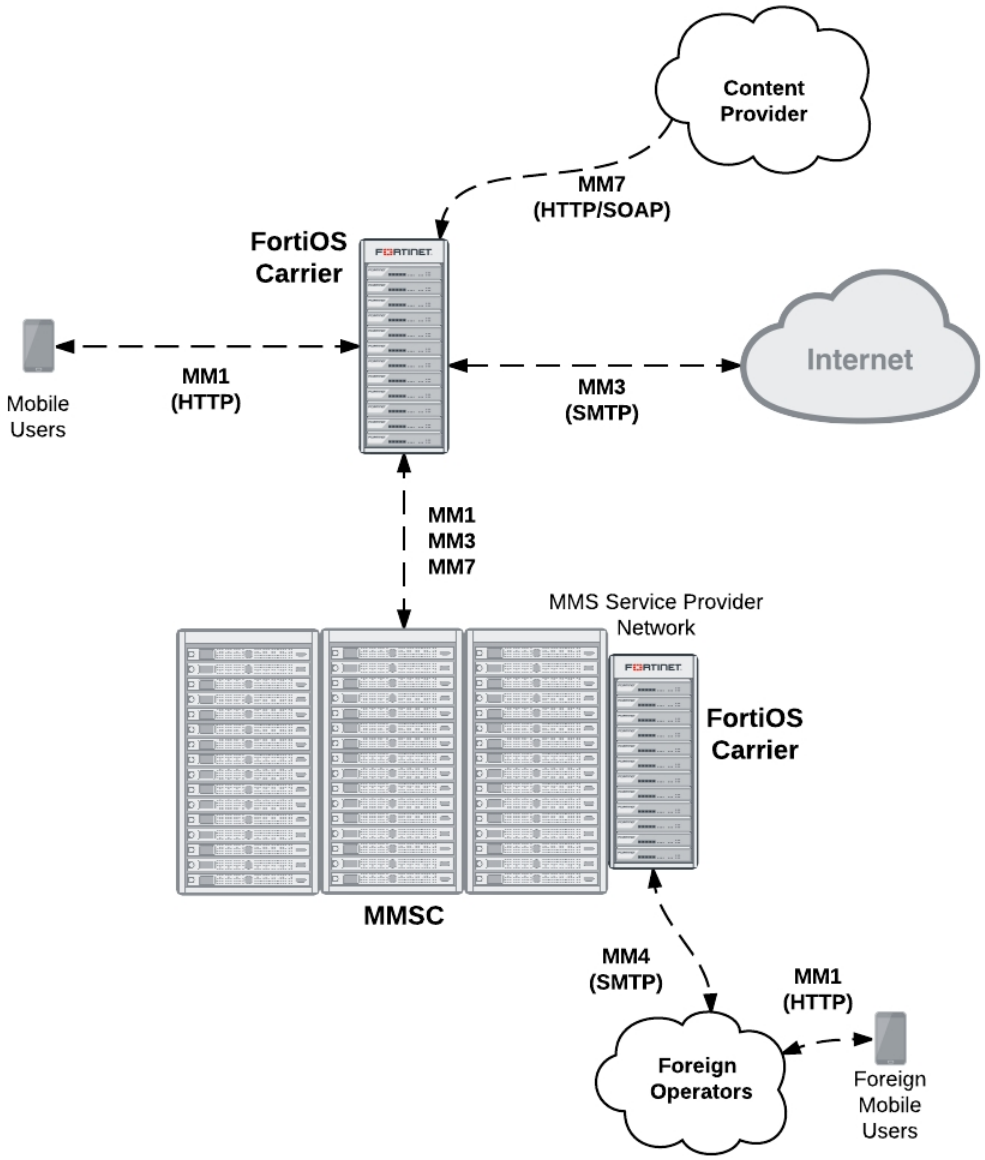
The method for determining whether a handset is MMS capable is not specified by the standards. A database is usually maintained by the operator, and in it each mobile phone number is marked as being associated with a legacy handset or not. It can be a bit hit and miss since customers can change their handset at will and this database is not usually updated dynamically.

Email and web-based gateways from MMSC to the Internet use the MM3 content interface. On the receiving side, the content servers can typically receive service requests both from WAP and normal HTTP browsers, so delivery via the web is simple. For sending from external sources to handsets, most carriers allow MIME encoded message to be sent to the receiver's phone number with a special domain.

How FortiOS Carrier processes MMS messages

MMS messages can be vectors for propagating undesirable content such as spam and viruses. FortiOS Carrier can scan MMS messages sent using the MM1, MM3, MM4, and MM7 content interfaces. You can configure FortiOS Carrier to scan MMS messages for spam and viruses by configuring and adding MMS protection profiles and adding the MMS protection profiles to security policies. You can also use MMS protection profiles to apply content blocking, carrier endpoint filtering, MMS address translation, sending MMS notifications, DLP archiving of MMS messages, and logging of MMS message activity.

FortiOS Carrier MMS processing



FortiOS Carrier can send MMS messages to senders informing those senders that their devices are infected. FortiOS Carrier can also send MMS notifications to administrators to inform them of suspicious activity on their networks.

For message floods and duplicate messages, FortiOS Carrier does not send notifications to message senders but does send notifications to administrators and sends messages to sender handsets to complete MM1 and MM4 sessions.

Where MMS messaging uses the TCP/IP set of protocols, SMS text messaging uses the Signaling System Number 7 (SS7) set of protocols, which is not supported by FortiOS.

FortiOS Carrier and MMS content scanning

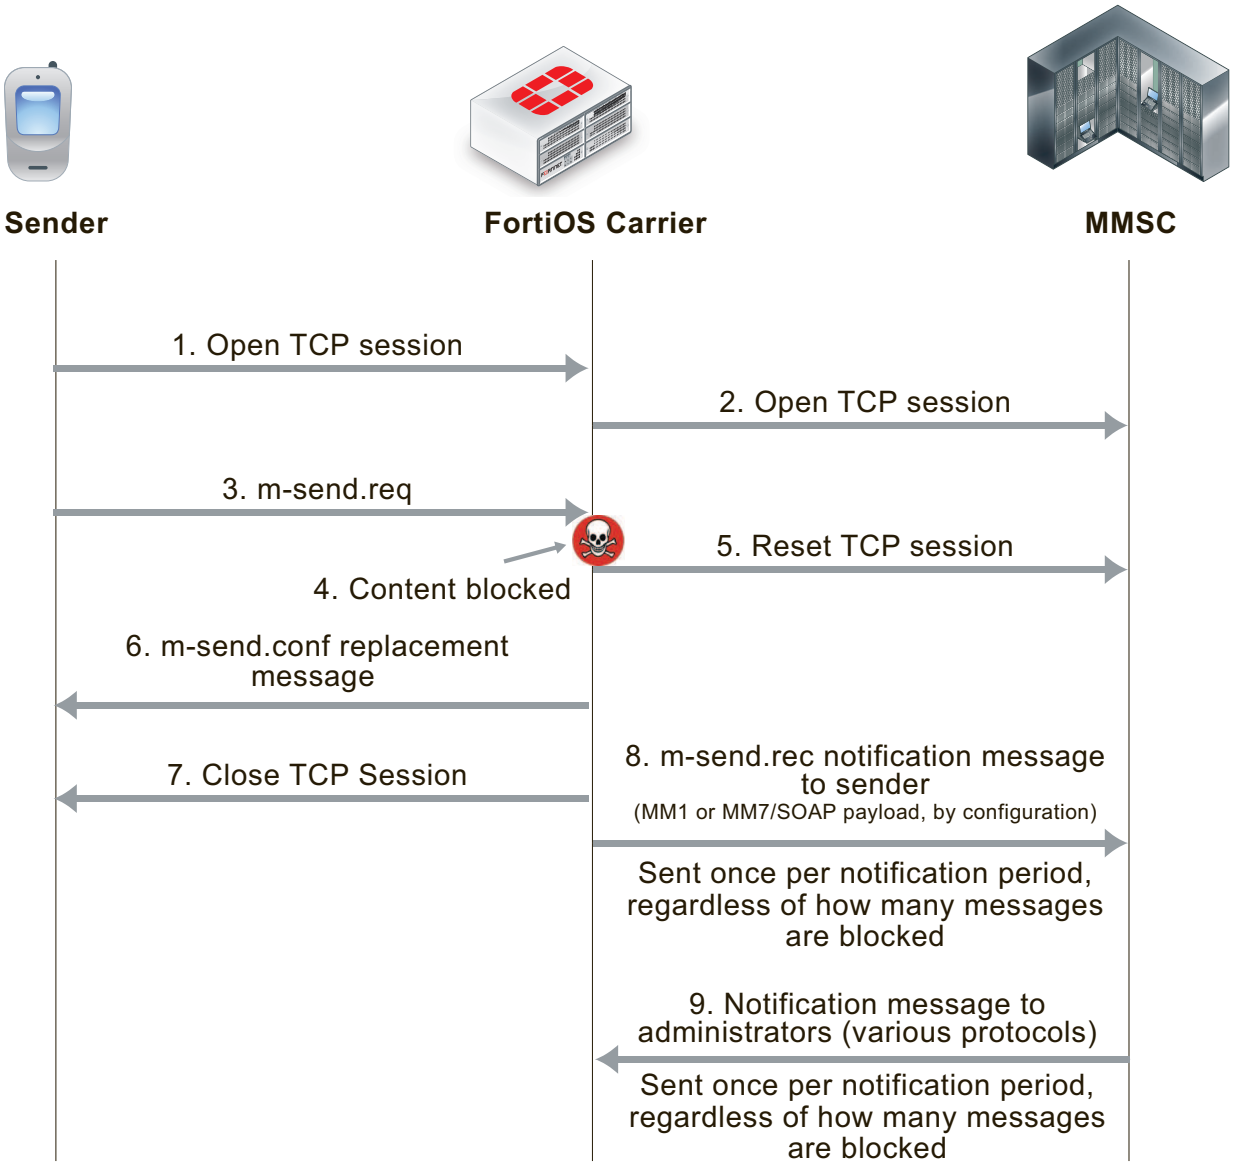
The following section applies to MMS content scanning, including virus scanning, file filtering, content spam filtering, carrier endpoint filtering, and MMS content checksum filtering.

MM1 Content Scanning

During MM1 content scanning a message is first transmitted from the sender, establishing a connection with the MMSC. FortiOS Carrier intercepts this connection and acts as the endpoint. FortiOS Carrier then establishes its own connection to the MMSC. Once connected, the client transmits its `m-send.req` HTTP post request to FortiOS Carrier which scans it according to the MMS protection profile settings. If the content is clean, the message is forwarded to the MMSC. The MMSC returns `m-send.conf` HTTP response through FortiOS Carrier to the sender.

If FortiOS Carrier blocks the message (for example because a virus was found, see the figure below), FortiOS Carrier resets the connection to the MMSC and sends `m-send.conf` HTTP response back to the sender. The response message can be customized using replacement messages. FortiOS Carrier then terminates the connection. Sending back an `m-send.conf` message prevents the sender from trying to send the message again.

MM1 MMS scanning of message sent by sender (blocking m.send.req messages)



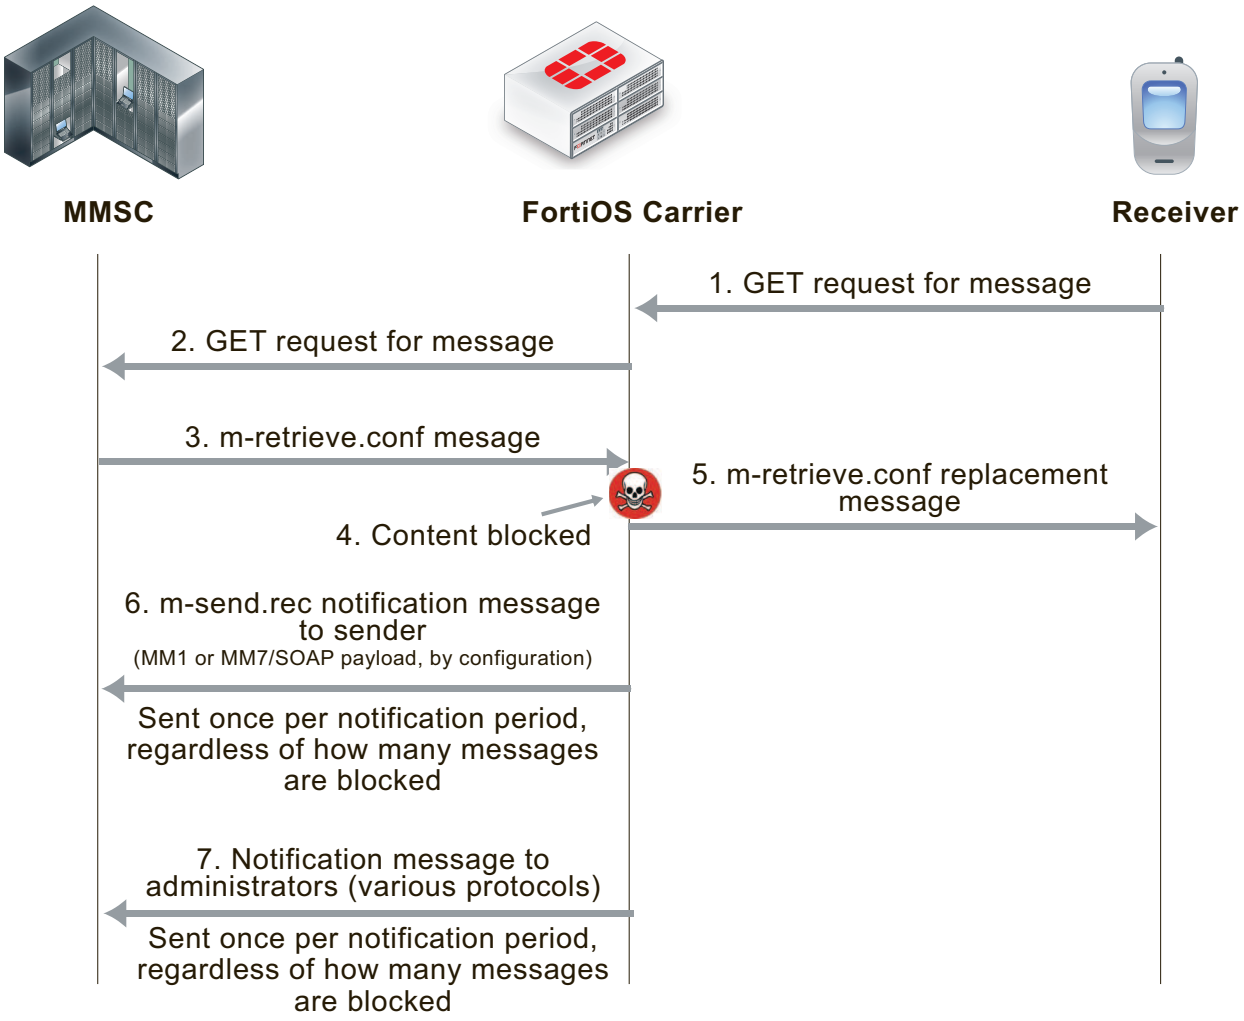
FortiOS Carrier also sends `m-send.rec` notifications messages to the MMSC that are then forwarded to the sender to notify them of blocked messages.

Filtering message retrieval

FortiOS Carrier intercepts the connection to the MMSC, and the m-retrieve.conf HTTP response from the MMSC is scanned according to the MMS content scanning settings. If the content is clean, the response is forwarded back to the client. If the content is blocked, FortiOS Carrier drops the connection to the MMSC. It then builds an m-retrieve.conf message from the associated replacement message and transmits this back to the client.

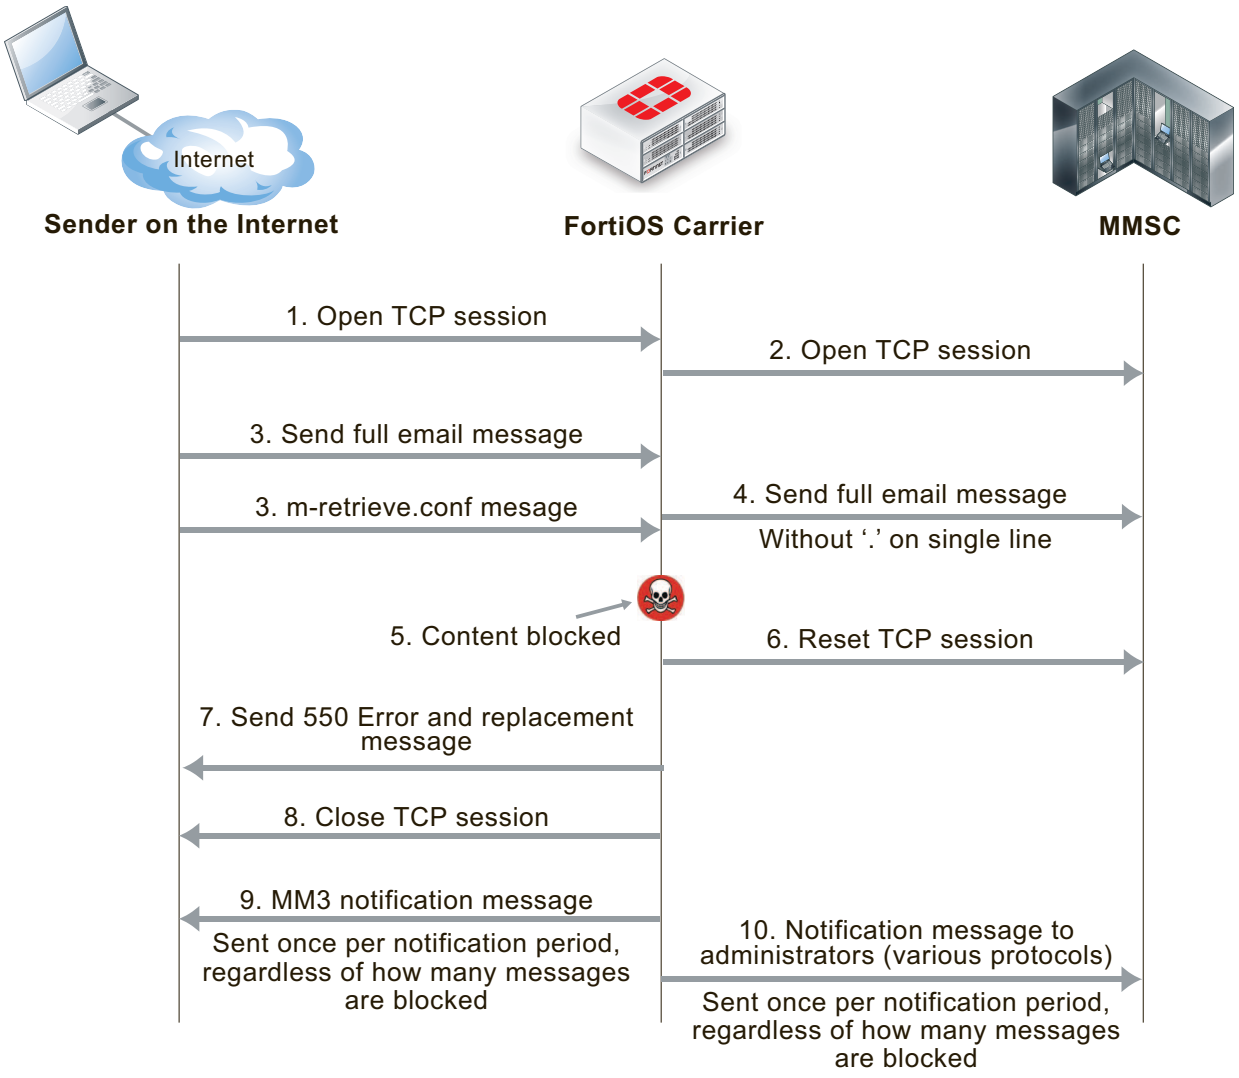
FortiOS Carrier also sends `m-send.rec` notifications messages to the MMSC that are then forwarded to the receiver to notify them of blocked messages.

MM1 MMS scanning of messages received by receiver (blocking m.retrieve.conf messages)

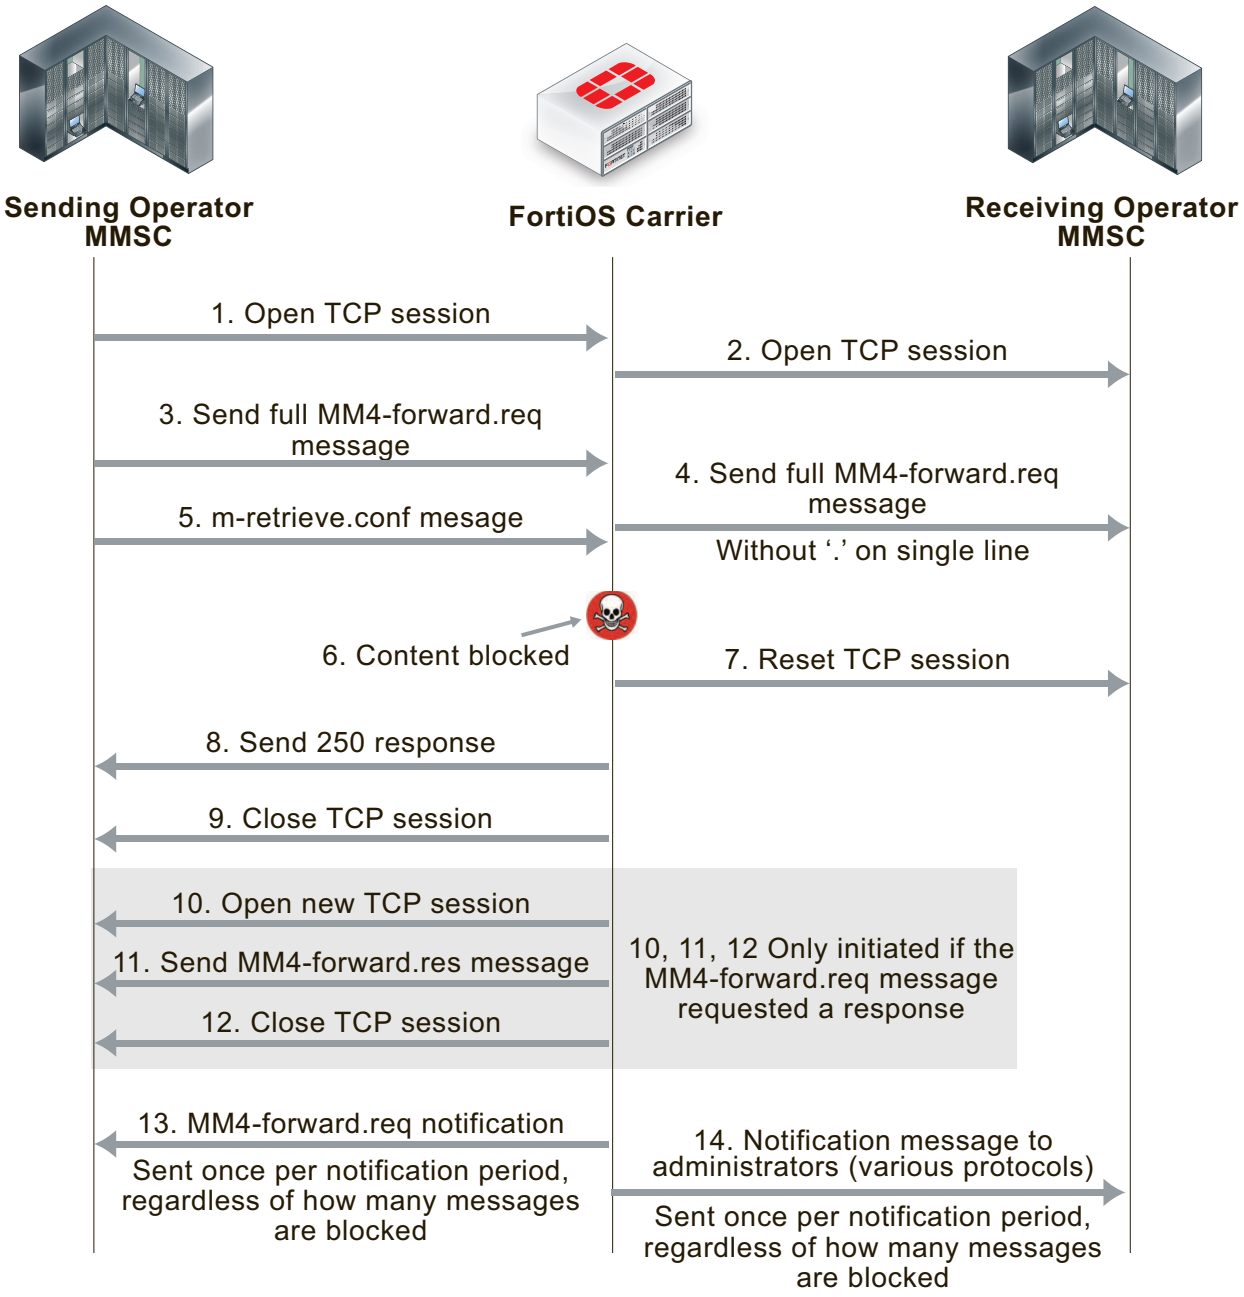


Filtering MM3 and MM4 messages works in an similar way to MM1 (see the figures below). FortiOS Carrier intercepts connections to the MMSC, and scans messages as configured. When messages are blocked, FortiOS Carrier closes sessions as required, sends confirmation messages to the sender, notifies administrators, and notifies senders and receivers of messages.

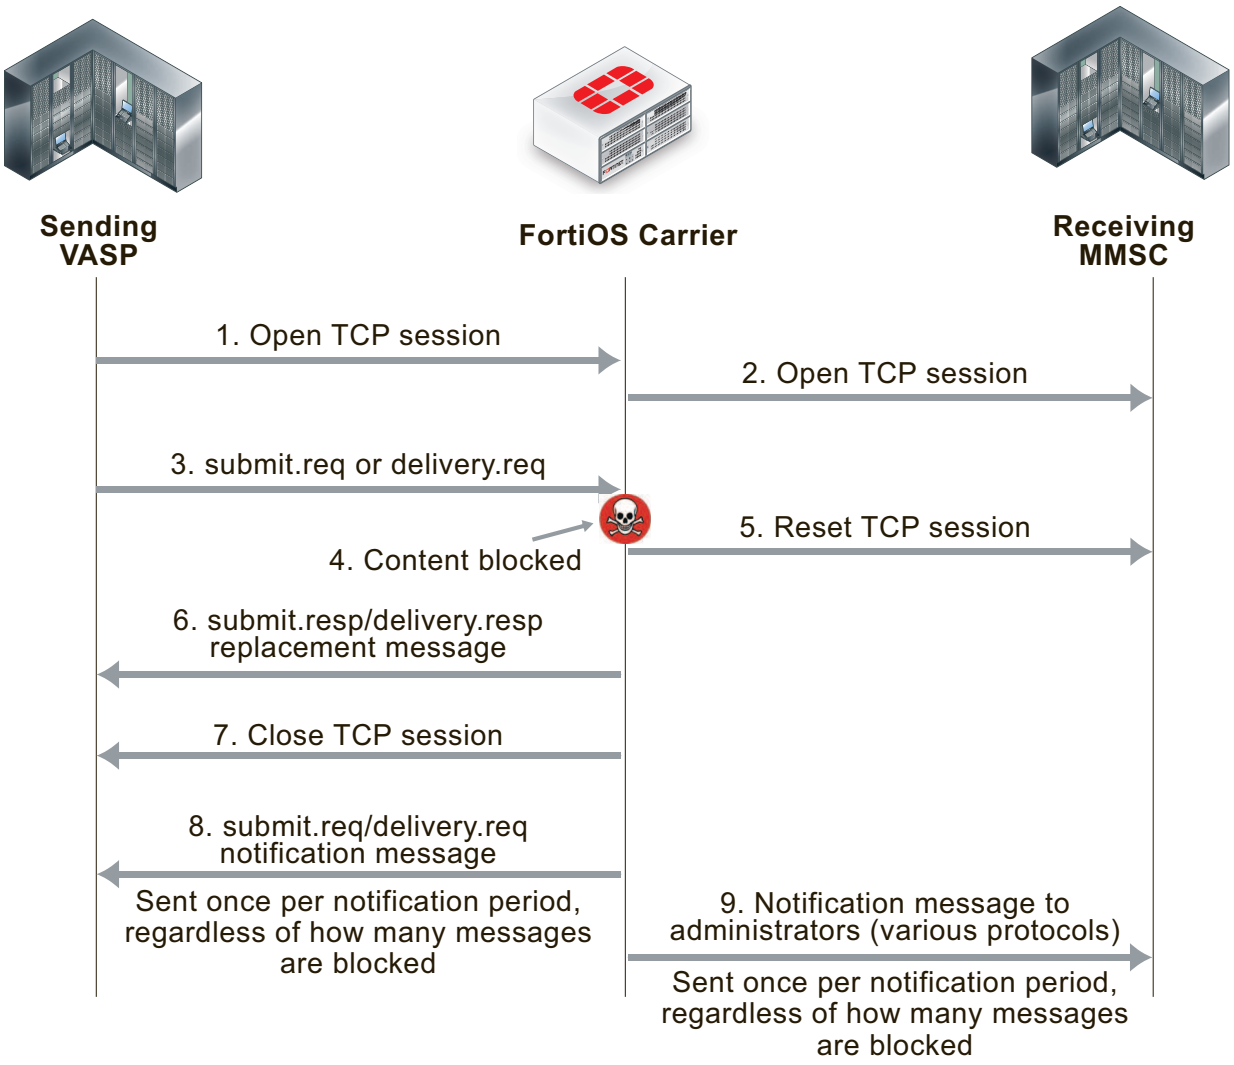
MM3 MMS scanning of messages sent from a sender on the Internet to an MMSC



MM4 MMS scanning of messages sent between operator MMSCs



MM7 MMS scanning of messages sent between a VASP and an MMSC



FortiOS Carrier and MMS duplicate messages and message floods

FortiOS Carrier detects duplicate messages and message floods for the MM1 and MM4 interfaces. How FortiOS Carrier detects and responds to duplicate messages and message floods is different from how FortiOS Carrier detects and responds to viruses and other MMS scanning protection measures.

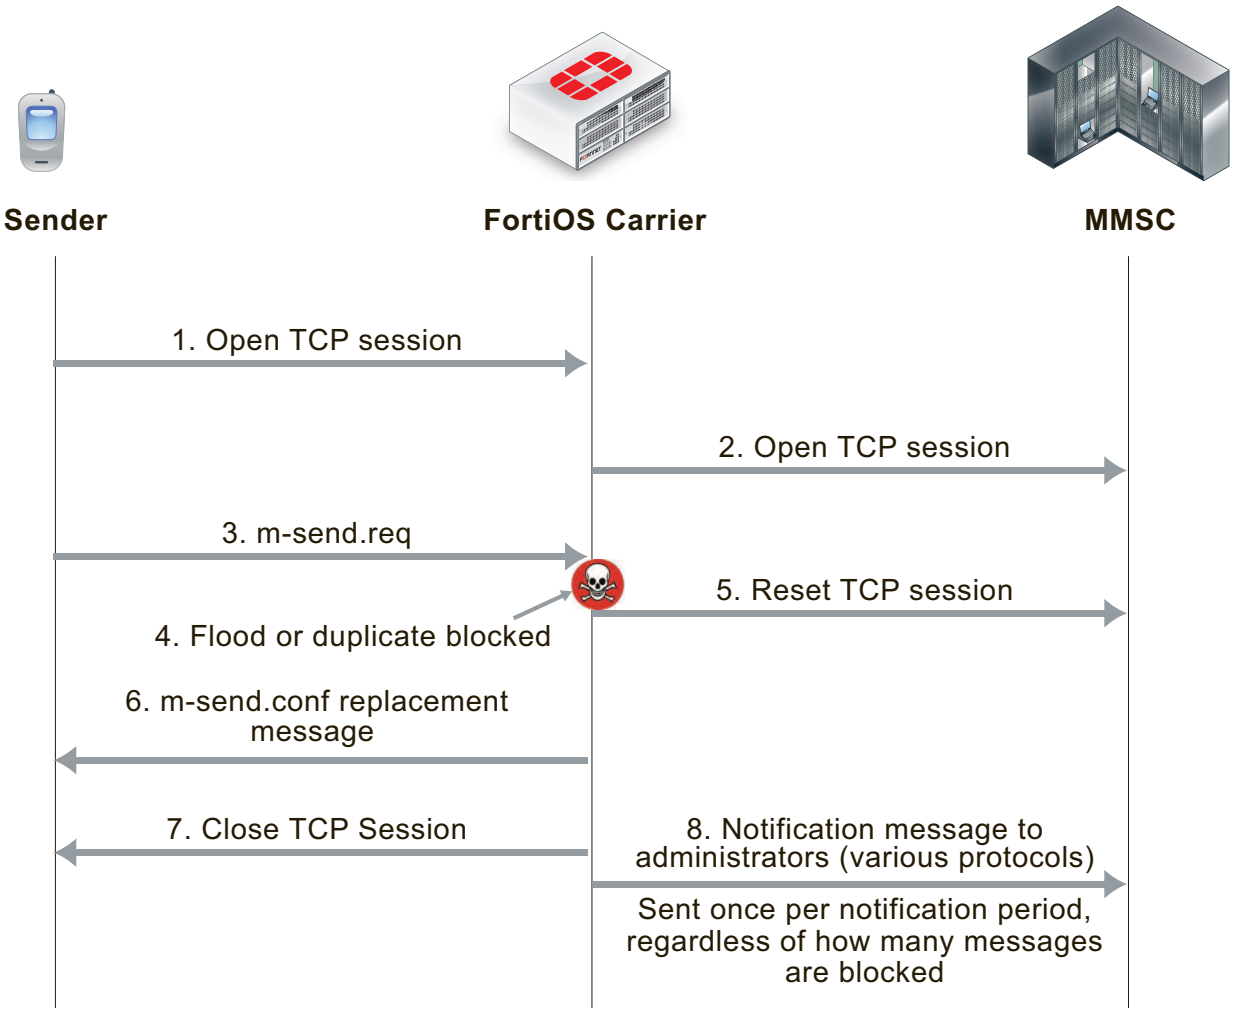
For message floods and duplicate messages, the sender does not receive notifications about floods or duplicate messages, as if the sender is an attacker they can gain useful information about flood and duplicate thresholds. Plus, duplicate messages and message floods are usually a result of a large amount of messaging activity and filtering of these messages is designed to reduce the amount of unwanted messaging traffic. Adding to the traffic by sending notifications to senders and receivers could result in an increase in message traffic.

You can create up to three thresholds for detecting duplicate messages and message floods. For each threshold you can configure the FortiOS Carrier unit to respond by logging the activity, archiving or quarantining the messages, notifying administrators of the activity, and by blocking the messages. In many cases you may only

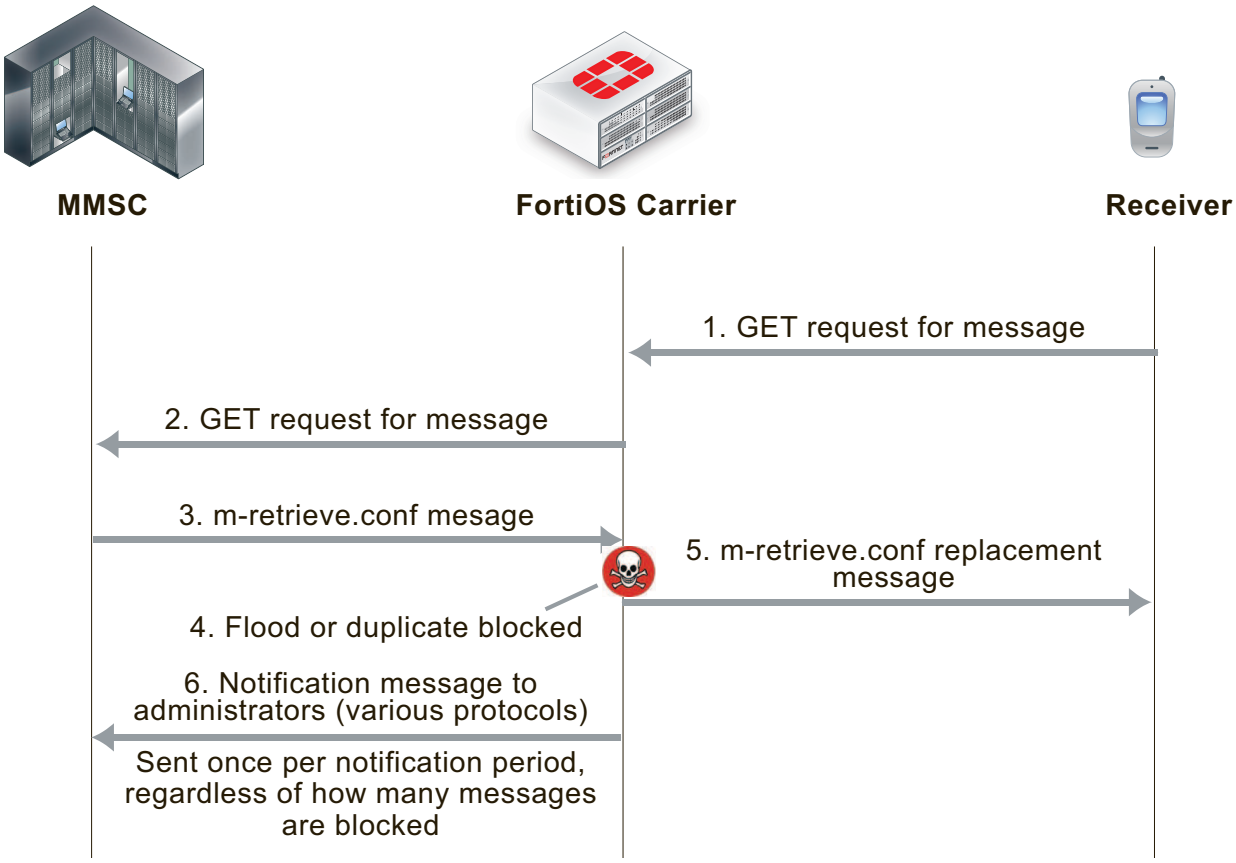
want to configure blocking for higher activity thresholds, and to just monitor and send administrator notifications at lower activity thresholds.

When a block threshold is reached for MM1 messages, FortiOS Carrier sends m-send.conf or m-retrieve.conf messages to the originator of the activity. These messages are sent to end the MM1 sessions, otherwise the originator would continue to re-send the blocked message. When a block threshold is reached for MM4, FortiOS Carrier sends a `MM4-forward.res` message to close the MM4 session. An MM4 message is sent only if initiated by the originating `MM4-forward.req` message.

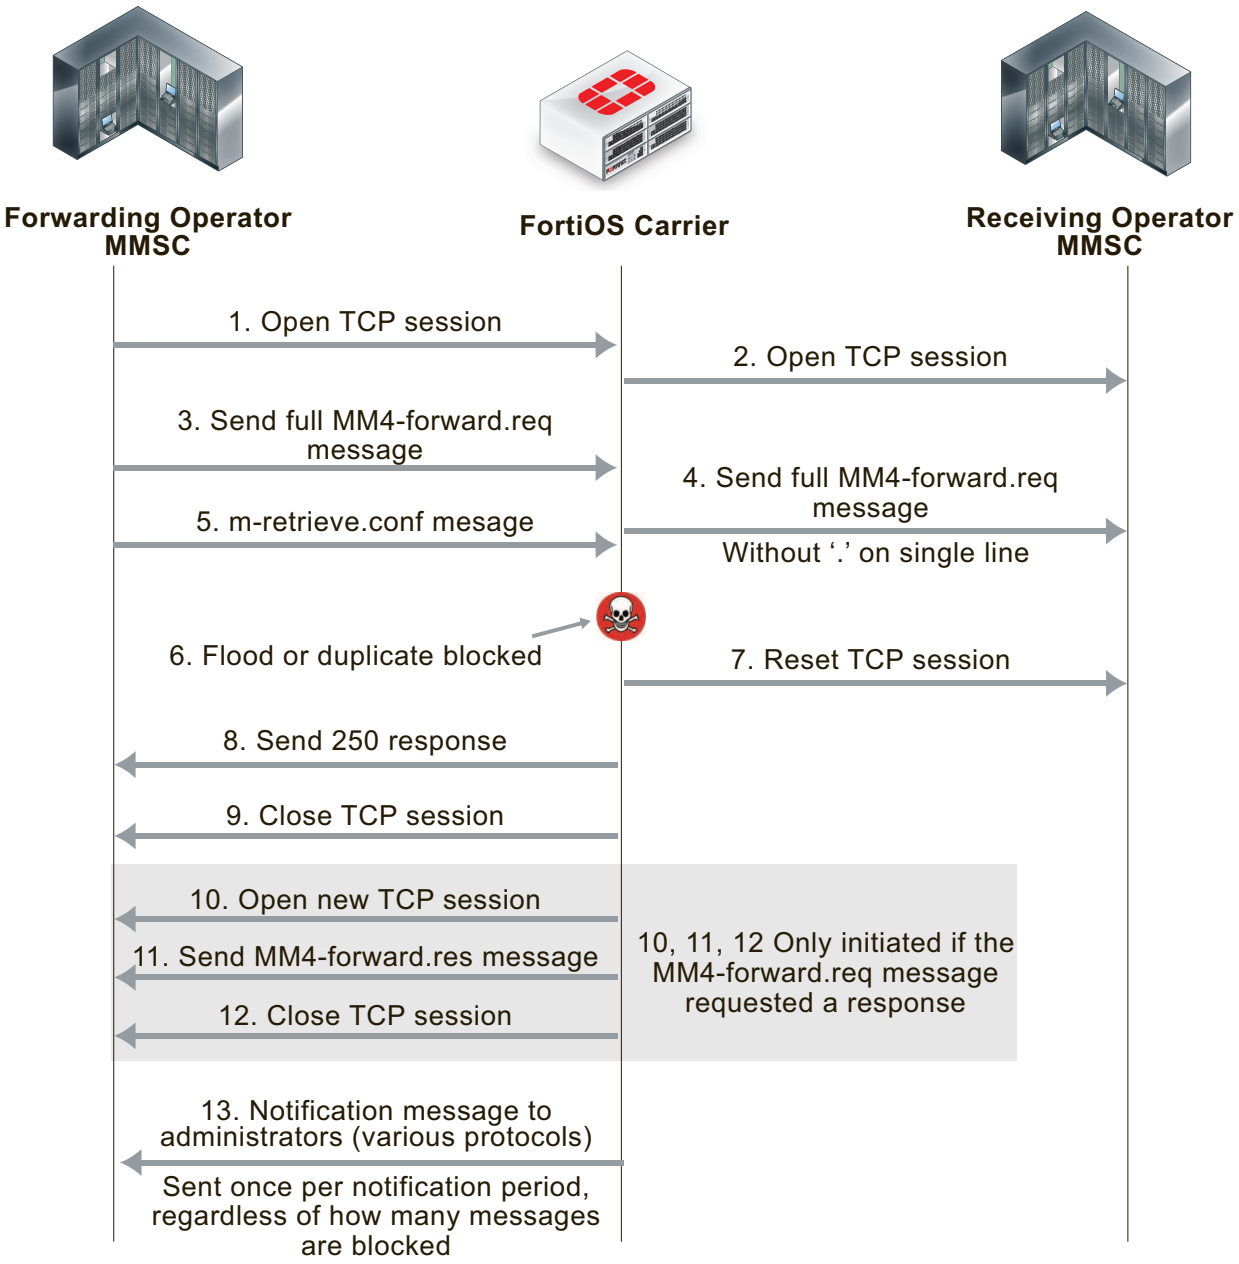
MM1 message flood and duplicate message blocking of sent messages



MM1 message flood and duplicate message blocking of received messages



MM4 message flood and duplicate message blocking



MMS protection profiles

An MMS protection profile is a group of settings that you can apply to an MMS session matched by a security policy.

MMS protection profiles are easy to configure and can be used by more than one security policy. You can configure a single MMS protection profile for the different traffic types handled by a set of security policies that require identical protection levels and types. This eliminates the need to repeatedly configure those same MMS protection profile settings for each individual security policy.

For example, while traffic between trusted and untrusted networks might need strict protection, traffic between trusted internal addresses might need only moderate protection. You would configure two separate MMS protection profiles to provide the different levels of protection: one for traffic between trusted networks, and one for traffic between trusted and untrusted networks.

Once you have configured the MMS Protection Profile, you need to add it to a security policy to apply the profile to MMS traffic.

Bypassing MMS protection profile filtering based on carrier endpoints

You can use carrier endpoint filtering to exempt MMS sessions from MMS protection profile filtering. Carrier endpoint filtering matches carrier endpoints in MMS sessions with carrier endpoint patterns. If you add a carrier endpoint pattern to a filter list and set the action to exempt from all scanning, all messages from matching carrier endpoints bypass MMS protection profile filtering. See Bypassing message flood protection based on user's carrier endpoints.

Applying MMS protection profiles to MMS traffic

To apply an MMS protection profile you must first create the MMS protection profile and then add the MMS protection profile to a security policy by enabling the Carrier security profile. The MMS protection profile then applies itself to the traffic accepted by that security policy.

MMS protection profiles can contain settings relevant to many different services. Each security policy uses the subset of the MMS protection profile settings that apply to the sessions accepted by the security policy. In this way, you might define just one MMS protection profile that can be used by many security policies, each policy using a different or overlapping subset of the MMS protection profile.

To add an MMS protection profile to a security policy

1. Go to **Security Profiles > MMS Profile**.
2. Select **Create New** to add an MMS protection profile.
3. Configure as needed, and save.
4. Go to **Policy & Objects > IPv4 Policy**.
5. Select **Create New** to add a security policy, or select an existing policy and **Edit** to add the MMS profile.
6. Configure the security policy as required.
7. Enable **MMS Profile**, and select the MMS profile to add to the security policy.
8. Select **OK**.

GTP basic concepts

GPRS currently supports data rates from 9.6kbps to more than 100 kbps, and is best suited for burst forms of traffic. GPRS involves both radio and wired components. The mobile phone sends the message to a base station unit (radio based), and the base station unit sends the message to the carrier network and eventually the Internet (wired carrier network).

The network system then either sends the message back to a base station and to the destination mobile unit, or forwards the message to the proper carrier's network where it gets routed to the mobile unit.

PDP Context

The packet data protocol (PDP) context is a connection between a mobile station and the end address that goes through the SGSN and GGSN. It includes identifying information about the mobile customer used by each server or device to properly forward the call data to the next hop in the carrier network, typically using a GTP tunnel between the SGSN and GGSN.

When a mobile customer has an active voice or data connection open, both the SGSN and GGSN have the PDP context information for that customer and session.

When a mobile phone attempts to communicate with an address on an external packet network, either an IP or X.25 address, the mobile station that phone is connected to opens a PDP context through the SGSN and GGSN to the end address. Before any traffic is sent, the PDP context must first be activated.

The information included in the PDP context includes the customer's IP address, the IMSI number of the mobile handset, and the tunnel endpoint ID for both the SGSN and GGSN. The ID is a unique number, much like a session ID on a TCP/IP firewall. All this information ensures a uniquely identifiable connection is made.

Since one mobile device may have multiple connections open at one time, such as data connections to different Internet services and voice connections to different locations, there may be more than one PDP context with the same IP address making the extra identifying information required.

The endpoint that the mobile phone is connecting to only knows about the GGSN — the rest of the GPRS connection is masked by the GGSN.

Along the PDP context path, communication is accomplished in using three different protocols.

- The connection between the Mobile Station and SGSN uses the SM protocol.
- Between SGSN and GGSN GTP is used.
- Between GGSN and the endpoint either IP or X.25 is used.

FortiOS Carrier is concerned with the SGSN to GGSN part of the PDP context — the part that uses GTP.

For more about PDP context, see Tunnel Management Messages.

Creating a PDP context

While FortiOS Carrier is concerned mostly with the SGSN to GGSN part of the PDP Context, knowing the steps involved in creating a PDP context helps understand the role each device, protocol, and message type plays.

Both mobile stations and GGSNs can create PDP contexts.

A Mobile Station creates a PDP context

1. The Mobile Station (MS) sends a `PDP activation request` message to the SGSN including the MS PDP address, and APN.
2. Optionally, security functions may be performed to authenticate the MS.
3. The SGSN determines the GGSN address by using the APN identifier.
4. The SGSN creates a downlink GTP tunnel to send IP packets between the GGSN and SGSN.
5. The GGSN creates an entry in its PDP context table to deliver IP packets between the SGSN and the external packet switching network.
6. The GGSN creates an uplink GTP tunnel to route IP-PDU from SGSN to GGSN.

7. The GGSN then sends back to the SGSN the result of the PDP context creation and if necessary the MS PDP address.
8. The SGSN sends an `Activate PDP context accept` message to the MS by returning negotiated the PDP context information and if necessary the MS PDP address.
9. Now traffic can pass from the MS to the external network endpoint.

A GGSN creates a PDP context

1. The network receives an IP packet from an external network.
2. The GGSN checks if the PDP Context has already been created.
3. If not, the GGSN sends a `PDU notification request` to the SGSN in order to initiate a PDP context activation.
4. The GGSN retrieves the IP address of the appropriate SGSN address by interrogating the HLR from the IMSI identifier of the MS.
5. The SGSN sends to the MS a request to activate the indicated PDP context.
6. The PDP context activation procedure follows the one initiated by the MS. See "A Mobile Station creates a PDP context".
7. When the PDP context is activated, the IP packet can be sent from the GGSN to the MS.

Terminating a PDP context

A PDP context remains open until it is terminated. To terminate the PDP context an MS sends a `Deactivate PDP context` message to the SGSN, which then sends a `Delete PDP Context` message to the GGSN. When the SGSN receives a PDP context deletion acknowledgment from the GGSN, the SGSN confirms to the MS the PDP context deactivation. The PDP can be terminated by the SGSN or GGSN as well with a slight variation of the order of the messages passed.

When the PDP Context is terminated, the tunnel it was using is deleted as well. If this is not completed in a timely manner, it is possible for someone else to start using the tunnel before it is deleted. This hijacking will result in the original customer being overbilled for the extra usage. Anti-overbilling helps prevent this. See Configuring Anti-overbilling in FortiOS Carrier.

GPRS security

The GPRS network has some built-in security in the form of GPRS authentication. However this is minimal, and is not sufficient for carrier network security needs. A GTP firewall, such as FortiOS Carrier, is required to secure the Gi, Gn, and Gp interfaces.

GPRS authentication

GPRS authentication is handled by the SGSN to prevent unauthorized GPRS calls from reaching the GSM network beyond the SGSN (the base station system, and mobile station). Authentication is accomplished using some of the customer's information with a random number and uses two algorithms to create ciphers that then allow authentication for that customer.

User identity confidentiality ensures that customer information stays between the mobile station and the SGSN — no identifying information goes past the SGSN. Past that point other numbers are used to identify the customer and their connection on the network.

Periodically the SGSN may request identity information from the mobile station to compare to what is on record, using the IMEI number.

Call confidentiality is achieved through the use of a cipher, similar to the GPRS authentication described earlier. The cipher is applied between the mobile station and the SGSN. Essentially a cipher mask is XORd with each outgoing frame, and the receiving side XORs with its own cipher to result in the original frame and data.

Parts of a GTPv1 network

A sample GTP network consists of the end handset sender, the sender's mobile station, the carrier's network including the SGSN and GGSN, the receiver's mobile station, and the receiver handset.

When a handset moves from one mobile station and SGSN to another, the handset's connection to the Internet is preserved because the tunnel the handset has to the Internet using GTP tracks the user's location and information. For example, the handset could move from one cell to another, or between countries.

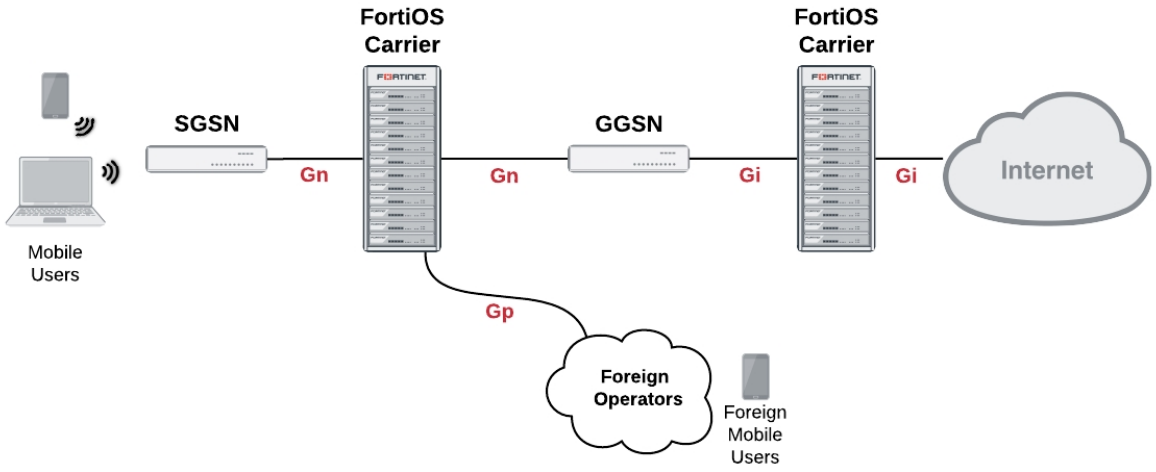
The parts of a GPRS network can be separated into the following groups according to the roles of the devices:

- Radio access to the GPRS network is accomplished by mobile phones and mobile stations (MS).
- Transport the GPRS packets across the GPRS network is accomplished by SGSNs and GGSNs, both local and remote, by delivering packets to the external services.
- Billing and records are handled by CDF, CFR, HLR, and VLR devices.

GPRS networks also rely on access points and PDP contexts as central parts of the communication structure. These are not actual devices, but they are still critical .

These devices, their roles, neighboring devices, the interfaces and protocols they use are outlined in the following table.

Carrier network showing the interfaces used (GTPv1)



Devices on a GTPv1 network

Device role	Neighboring Devices	Interfaces used	Protocols used
Mobile Users	Mobile Stations (MS)	Radio Access Technology (RAT)	

Device role	Neighboring Devices	Interfaces used	Protocols used
Mobile Stations (MS)	Mobile Users, SGSN	Gb	IP, Frame Relay
SGSN (local)	MS, SGSN (local or remote), GGSN (local and remote), CDR, CFR, HLR, VLR	Ga, Gb, Gn, Gp, Gz	IP, Frame Relay, GTP, GTP'
SGSN (remote)	SGSN (local)	Gn	GTP
GGSN (local)	SGSN (local or remote), GGSN (local and remote), CDR, CFR, HLR, VLR	Ga, Gi, Gn, Gp, Gz	IP, GTP, GTP'
GGSN (remote)	SGSN (local), WAP gateway, Internet, other external services	Gi, Gp	IP, GTPv1
CDR, CFR	SGSN (local), GGSN (local)	Ga, Gz	GTP'
HLR, VLR	SGSN (local), GGSN (local)	Ga, Gz	GTP'

Radio access

For a mobile phone to access the GPRS core network, it must first connect to a mobile station. This is a cellular tower that is connected to the carrier network.

How the mobile phone connects to the mobile station (MS) is determined by what Radio Access Technologies (RATs) are supported by the MS.

Transport

Transport protocols move data along the carrier network between radio access and the Internet or other carrier networks.

FortiOS Carrier should be present where information enters the Carrier network, to ensure the information entering is correct and not malicious. This means a Carrier-enabled FortiGate unit intercepts the data coming from the SGSN or foreign networks destined for the SSGN or GGSN onto the network, and after the GGSN as the data is leaving the network.

GTP

GPRS Tunnelling Protocol (GTP) is a group of IP-based communications protocols used to carry General Packet Radio Service (GPRS) within Global System for Mobile Communications (GSM) and Universal Mobile Telecommunications System (UMTS) networks. It allows carriers to transport actual cellular packets over their network via tunneling. This tunneling allows users to move between SGSNs and still maintain connection to the the Internet through the GGSN.

GTP has three versions version 0, 1, and 2. GTP1 and GTP2 are supported by FortiOS Carrier. The only GTP commands that are common to all forms of GTP are the echo request/response commands that allow GSNs to verify up to once every 60 seconds that neighboring GSNs are alive.

GTPv0

There have been three versions of GTP to date. The original version of GTP (version 0) has the following differences from version GTPv1.

- the tunnel identification is not random
- there are options for transporting X.25
- the fixed port number 3386 is used for all functions, not just charging
- optionally TCP is allowed as a transport instead of UDP
- not all message types are supported in version 0

GTPv1

On a GPRS network, Packet Data Protocol (PDP) context is a data structure used by both the Serving GPRS Support Node (SGSN) and the Gateway GPRS Support Node (GGSN). The PDP context contains the subscribers information including their access point, IP address, IMSI number, and their tunnel endpoint ID for each of the SGSN and GGSN.

The Serving GPRS Support Node (SGSN) is responsible for the delivery of data packets from and to the mobile stations within its geographical service area. Its tasks include packet routing and transfer, mobility management (attach/detach and location management), logical link management, and authentication and charging functions. The location register of the SGSN stores location information (e.g., current cell, current VLR) and user profiles (e.g., IMSI, address(es) used in the packet data network) of all GPRS users registered with this SGSN.

GTPv1-C

GTPv1-C refers to the control layer of the GPRS Transmission network. This part of the protocol deals with network related traffic.

FortiOS Carrier handles GTPv1-C in GTPv1 by using the Tunnel Endpoint IDentifier (TEID), IP address and a Network layer Service Access Point Identifier (NSAPI), sometimes called the application identifier, as an integer value that is part of the PDP context header information used to identify a unique PDP context in a mobile station, and SGSN.

For more information on GTPv1-C, see GTP-C messages.

GTPv1-U

GTPv1-U is defined in 3GPP TS 29.281 and refers to the user layer of the GPRS Tunneling network. This part of the protocol deals with user related traffic, user tunnels, and user administration issues.

A GTPv1-U tunnel is identified by a TEID, an IP address, and a UDP port number. This information uniquely identifies the limb of a GTPv1 PDP context. The IP address and the UDP port number define a UDP/IP path, a connectionless path between two endpoints (i.e. SGSN or GGSN). The TEID identifies the tunnel endpoint in the receiving GTPv1-U protocol entity; it allows for the multiplexing and demultiplexing of GTP tunnels on a UDP/IP path between a given GSN-GSN pair. For more information on GTPv1-U, see GTP-U messages.

The GTP core network consists of one or more SGSNs and GGSNs.

GGSN

The Gateway GPRS Support Node (GGSN) connects the GPRS network on one side via the SGSN to outside networks such as the Internet. These outside networks are called packet data networks (PDNs). The GGSN acts as an edge router between the two different networks — the GGSN forwards incoming packets from the external PDN to the addressed SGSN and the GGSN also forwards outgoing packets to the external PDN. the GGSN also converts the packets from the GPRS packets with SGSN to the external packets, such as IP or X.25.

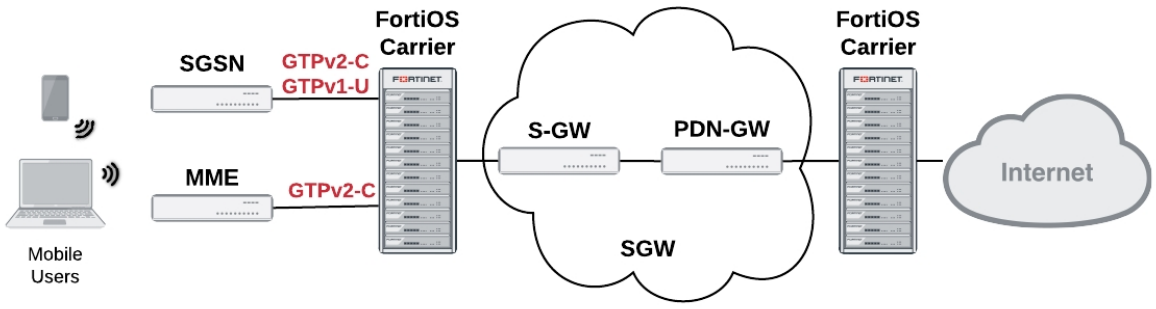
SGSN

The Serving GPRS Support Node (SGSN) connects the GPRS network to GTPv1 compatible mobile stations, and mobile units (such as UTRAN and ETRAN) on one side and to the gateway node (GGSN), which leads to external networks, on the other side. Each SGSN has a geographical area, and mobile phones in that area connect to the GPRS network through this SGSN. The SGSN also maintains a location register that contains customer's location and user profiles until they connect through a different SGSN at which time the customer information is moved to the new SGSN. This information is used for packet routing and transfer, mobility management also known as location management, logical link management, and authentication and billing functions.

GTPv2

GTPv2, defined in 3GPP TS 29.274, is dramatically differnet from GTPv1, defined in 3GPP TS 29.060. Where in GTPv1 the tunnel is between the SGSN and the GGSN, in GTPv2 The SGSN is between the MME and the LTE Serving Gateway (S-GW), beyond which is the PDN gateway (P-GW). Even tunnel management messages have changed significantly.

Network diagram for GTPv2



Device roles on a GTPv2 network

Device role	Neighboring Devices	Interfaces used	Protocols used
Mobile Users	Mobile Stations (MS)	Radio Access Technology (RAT)	--

Device role	Neighboring Devices	Interfaces used	Protocols used
GTPv1 Mobile Stations (MS)	Mobile Users, SGSN	Gb	IP, Frame Relay
GTPv2 Mobile Stations (MS)	Mobile Users, MME	???	IP, Frame Relay
SGSN (local)	GTPv1 MS, SGSN, S-GW	???	IP, Frame Relay, GTPv1, GTP'
S-GW	SGSN, MME, P-GW	???	IP, GTPv2, GTP'
P-GW	S-GW, Internet, other external services	???	IP, GTPv2

GTPv2-C

GTPv2-C is the control layer messaging for GTPv2. It is used by LTE mobile stations, SGSN units for backwards compatibility, and SGWs that are the gateway to other networks. The messaging is very different from GTPv1. GTPv2-C is required to communicate with the Mobility Management Entity (MME) to create, change and delete EPS bearers when handover events happen, and to create Forwarding tunnels. The protocol is also used to communicate with the Serving Gateway (SGW) which has the S-GW and PDN-GW interfaces, and the Serving GPRS Support Node (SGSN).

MME

MME essentially fills the role of the SGSN in a GTPv1 network — it is how the mobile stations gain access to the Carrier network. GTPv2 supports different mobile stations than GTPv1, so MME handles the GTPv2 MSes and SGSN handles the GTPv1 MSes

Billing and records

A major part of the GPRS network is devoted to billing. Customer billing requires enough information to identify the customer, and then billing specific information such as connection locations and times, as well as amount of data transferred. A modified form of GTP called GTP' is used for billing. The home location records and visitor location records store information about customers that is critical to billing.

GTP' (GTP prime)

GTP is used to handle tunnels of user traffic between SGSNs and GGSNs. However for billing purposes, other devices that are not supported by GTP are required. GTP' (GTP prime) is a modified form of GTP and is used to communicate with these devices such as the Charging Data Function (CDF) that communicates billing information to the Charging Gateway Function (CGF). In most cases, GTP' transports user records from many individual network elements, such as the GGSNs, to a centralised computer which then delivers the charging data more conveniently to the network operator's billing center, often through the CGF. The core network sends charging information to the CGF, typically including PDP context activation times and the quantity of data which the end user has transferred.

GTP' is used by the Ga and Gz interfaces to transfer billing information. GTP' uses registered UDP/TCP port 3386. GTP' defines a different header, additional messages, field values, as well as a synchronisation protocol to avoid losing or duplicating CDRs on CGF or SGSN/GGSN failure. Transferred CDRs are encoded in ASN.1.

HLR

The Home Location Register (HLR) is a central database that contains details of each mobile phone subscriber that is authorized to use the GSM core network. There can be several logical, and physical, HLRs per public land mobile network (PLMN), though one international mobile subscriber identity (IMSI)/MSISDN pair can be associated with only one logical HLR (which can span several physical nodes) at a time. The HLRs store details of every SIM card issued by the mobile phone operator. Each SIM has a unique identifier called an IMSI which is the primary key to each HLR record.

VLR

The Visitor Location Register (VLR) is a database which stores information about all the mobile devices that are currently under the jurisdiction of the Mobile Switching Center which it serves. Of all the information the VLR stores about each Mobile Station, the most important is the current Location Area Identity (LAI). This information is vital in the call setup process.

Whenever an MSC detects a new MS in its network, in addition to creating a new record in the VLR, it also updates the HLR of the mobile subscriber, informing it of the new location of that MS.

For more information on GTP', see GTP-U and Charging Management Messages.

GPRS network common interfaces

There are interfaces for each connection on the GPRS network. An interface is an established standard form of communication between two devices. Consider a TCP/IP network. In addition to the transport protocol (TCP) there are other protocols on that network that describe how devices can expect communications to be organized, just like GPRS interfaces.

Interfaces between devices on the network

There are a series of interfaces that define how different devices on the carrier network communicate with each other. There interfaces are called Ga to Gz, and each one defines how a specific pair of devices will communicate. For example Gb is the interface between the base station and the SGSN, and Gn is one possible interface between the SGSN and GGSN.

The SGSN and GGSN keep track of the CDR information and forward it to the Charging Data Function (CDF) using the Gr interface between the SGSN and home location register (HLR), Gs interface between the SGSN and MSC (VLR), Gx interface between the GGSN and the Charging Rules Function (CRF), Gy between the GGSN and online charging system (OCS), and finally Gz which is the off-line (CDR-based) charging interface between the GSN and the CG that uses GTP'.

Each of these interfaces on the GPRS network is has a name in the format of `Gx` where `x` is a letter of the alphabet that determines what part of the network the interface is used in. It is common for network diagrams of GPRS networks to include the interface name on connections between devices.

The Carrier-enabled FortiGate unit only provides protection on the Gn, Gp, and Gi interfaces.

GPRS network interfaces, their roles, and billing

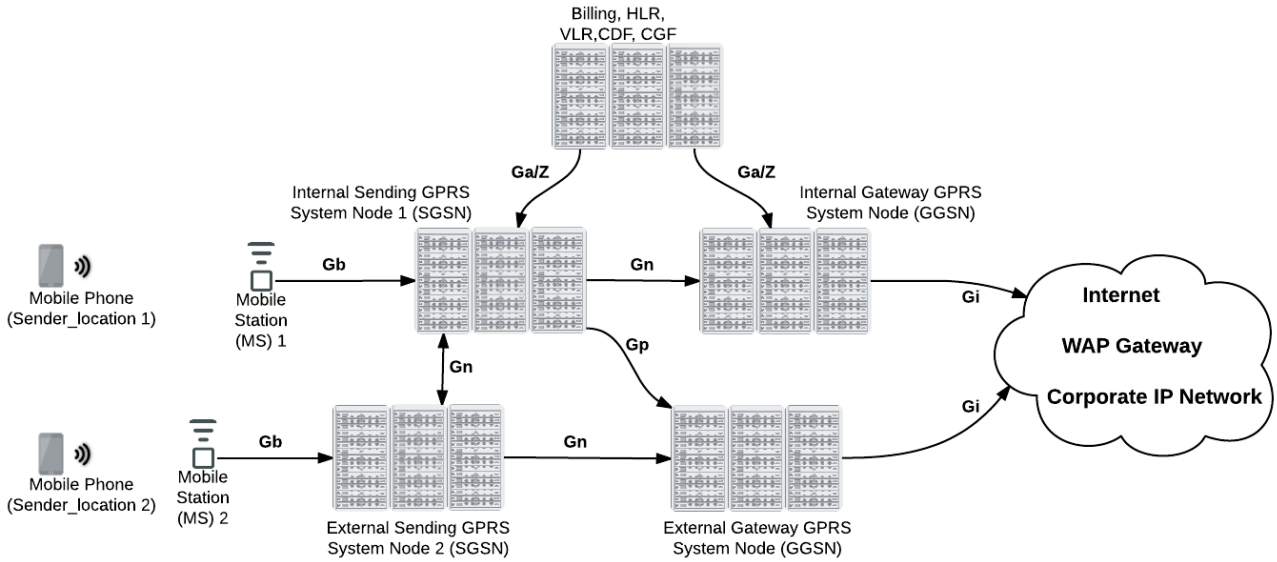
Name	Device connections that use this interface	Traffic Protocol used	Its role or how it affects billing
Ga	CDR and GSN (SGSNs and GGSNs)	GTP' - GTP modified to include CDR role	CDR have the accounting records, that are compiled in the GSN and then sent to the Charging Gateway (CG)
Gb	MS and SGSN	Frame Relay or IP	When an IP address moves to a new MS, the old MS may continue to use and bill that IP address.
Gi	GGSN and public data networks (PDNs)	IP based	This is the connection to the Internet. If the GTP tunnel is deleted without notifying the Gi interface, the connection may remain open incurring additional charges. FortiOS Carrier adds this interface to a firewall. See Anti-overbilling with FortiOS Carrier.
Gn	SGSN and external SGSNs and internal GGSNs	GTP	When the GTP tunnel is deleted, need to inform other interfaces immediately to prevent misuse of connections remaining open. FortiOS Carrier adds this interface to a firewall.
Gp	Internal SGSN and external GGSNs	GTP	
Gz	GSN (SGSN and GGSN) and the charging gateway (CG)	GTP'	Used for the offline charging interface. Ga is used for online charging.

Corporate customers may have a direct connection to the Gi interface for higher security. The Gi interface is normally an IP network, though a tunnelling protocol such as GRE or IPsec may be used instead.

Packet flow through the GPRS network

To better understand the GPRS network, we will follow the path data takes for a normal connection. For this example a call placed from a mobile phone involves accessing services on the Internet.

Sample GPRS network topology



1. A mobile phone places a call using a mobile station (MS). This connection between the mobile phone and the MS is a radio connection using one of the radio access technologies. See Radio Access Technology (RAT) type.
2. The MS connects to a GPRS System Node (GSN) specifically a Sending GSN. This connection uses the Gb interface and typically uses IP address or Frame Relay.
3. The SGSN checks the mobile phone information located in the home location register (HLR) or visitor location register (VLR) to ensure there is subscriber information for that phone. If this mobile phone is from another network, the SGSN uses the VLR and updates its home carrier's information with its current location and information. This connection involves the Ga or Gz interfaces, and uses the GTP' protocol for communication.
4. The SGSN checks to make sure the phone did not transfer this connection from a different MS. If it did, the connection has already been established (along with the billing) and is handed off to this SGSN. If the call is being handed over from another SGSN, it will use the Gn interface between the two SGSNs.
5. The SGSN sends GTP messages to the local external Gateway GSN (GGSN) to create a GTP tunnel for this PDP context to access the Internet. It is possible that a remote GGSN has access to a service, such as a WAP gateway, that the local GGSN is missing. In this situation, the local SGSN uses the Gp interface to connect to the remote GGSN. Both the Gn and Gp interfaces use GTP.
6. The both the local and remote GGSNs connect to external services outside the GPRS network. These services can include a WAP gateway, a corporate IP network directly connected to the GPRS network, or the Internet. The connection from the GGSN to the external services uses the Gi interface.

SCTP

As of FortiOS version 5.0, the FortiGate natively handles SCTP (Stream Control Transport Protocol) traffic, as an alternative to TCP and UDP for use in Carrier networks. The FortiGate handles SCTP as if it would any other traffic.

Overview

SCTP is a connection-oriented transport protocol that overcomes some of the limitations of both TCP and UDP that prevent reliable transfer of data over IP-based networks (such as those used by telephony systems and carrier networks). The 'Stream' in SCTP refers to the sequence of user messages or packets that are considered at the same time to be individual objects and also treated as a whole by networked systems. SCTP is less vulnerable to congestion and flooding due to more advanced error handling and flood protection built into the protocol.

SCTP features as compared to TCP and UDP

Feature	SCTP	TCP	UDP
State required at each endpoint	yes	yes	no
Reliable data transfer	yes	yes	no
Congestion control and avoidance	yes	yes	no
Message boundary conservation	yes	no	yes
Path MTU discovery and message fragmentation	yes	yes	no
Message bundling	yes	yes	no
Multi-homed hosts support	yes	no	no
Multi-stream support	yes	no	no
Unordered data delivery	yes	no	yes
Security cookie against SYN flood attack	yes	no	no
Built-in heartbeat (reachability check)	yes	no	N/A

All of these features are built into the design of the Protocol, and the structure of SCTP packets and networks. The FortiGate unit interprets the traffic and provides the necessary support for maintenance and verification features, but the features are not FortiGate specific. These features are documented in greater detail below.

State required at each endpoint

Constant back and forth acknowledgement and content verification messages are sent between all SCTP peer endpoints, and all endpoints' state machine actions must be synchronized for traffic to flow.

Reliable data transfer

SCTP places data and control information (eg. source, destination, verification) into separate messages, both sharing the same header in the same SCTP packet. This allows for constant verification of the contained data at both ends and along the path, preventing data loss or fragmentation. As well, data is not sent in an interruptible stream as in TCP.

Congestion control and avoidance

Built-in, constantly updating path detection and monitoring automatically redirect packets along alternate paths in case of traffic congestion or inaccessible destinations. For deliberate/malicious congestion control, see the below section on Security cookie against SYN flood attack.

Message boundary conservation

SCTP is designed in such a way that no matter how messages are divided, redirected, or fragmented, the message boundaries will be maintained within the packets, and all messages cannot be appended without tripping verification mechanisms.

Path MTU discovery and message fragmentation

SCTP is capable of Path Maximum Transmission Unit discovery, as outlined in RFC4821. Two specific alterations have been made to how SCTP handles MTU. First, that endpoints will have separate MTU estimates for each possible multi-homed endpoint. Second, that bundled message fragments (as explained below) will be directed based on MTU calculations, so that retransmissions (if necessary) will be sent without delay to alternate addresses.

Message bundling

SCTP is a message-oriented protocol, which means that despite being a streaming data protocol, it transports a sequence of specific messages, rather than transporting a stream of bytes (like TCP). Since some data transmissions are small enough to not require a complete message's worth of content, so multiple pieces of content will be transmitted simultaneously within the messages.

Multi-homed hosts support

SCTP supports multi-homing, which is a network structure in which one or multiple sources/destinations has more than one IP address. SCTP can adapt to multi-homing scenarios and redirect traffic to alternate IP addresses in case of failure.

Multi-stream support

Due to the message bundling feature allowing for multiple pieces of content to be sent in messages at once, SCTP can 'multi-stream' content, by deliberately dividing it among messages at a fixed rate, so that multiple types of content (eg. both images and text) can be loaded at once, at the same pace.

Unordered data delivery

With control messages in every packet to provide verification of any packet's data and its place in the stream, the data being transmitted can actually arrive in any order, and verify that all has arrived or that some is missing.

Security cookie against SYN flood attack

Since every packet contains verification of its place in the stream, it makes it easy for the protocol to detect when redundant, corrupted or malicious packets flood the path, and they are automatically dropped when necessary.

Built-in heartbeat (reachability check)

Endpoints automatically send specific control chunks among the other SCTP packet information to peer endpoints, to determine the reachability of the destination. Hearthbeat acknowledgement packets are returned if the destination is available.

SCTP Firewall

FortiGate stateful firewalls will protect and inspect SCTP traffic, according to RFC4960. SCTP over IPsec VPN is also supported. The FortiGate device is inserted as a router between SCTP endpoints. It checks SCTP Syntax for the following information:

- Source and destination port
- Verification Tag
- Chunk type, chunk flags, chunk length
- Sequence of chunk types
- Associations

The firewall also oversees and maintains several SCTP security mechanisms:

- SCTP four-way handshake
- SCTP heartbeat
- NAT over SCTP

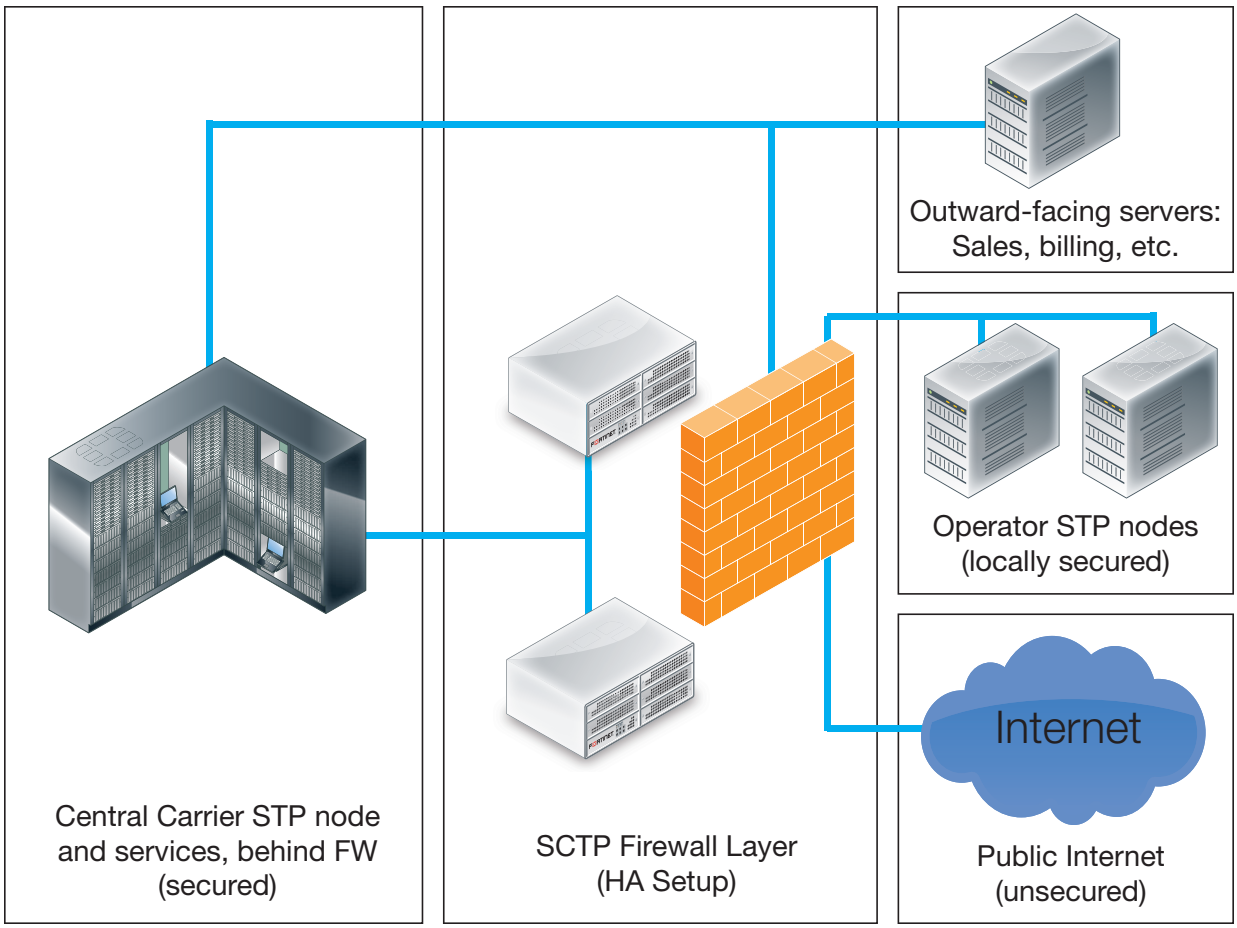
The firewall has IPS DoS protection against known threats to SCTP traffic, including INIT/ACK flood attacks, and SCTP fuzzing.

SCTP example scenario

An ideal SCTP configuration for a Carrier serving multiple operators/service providers involves a unified Firewall, securing all incoming and outgoing traffic over the Carrier network, whether it be standard web traffic, GTP or other carrier traffic, or corporate traffic for the Carrier company.

One best practice method to provide a unified firewall with built-in redundancy is to make use of multiple FortiGate units, connected in a High Availability cluster. Also, there are additional methods that can be applied to ease the complexity of managing multiple services, functions, and traffic types across multiple devices.

Sample SCTP Network Topology

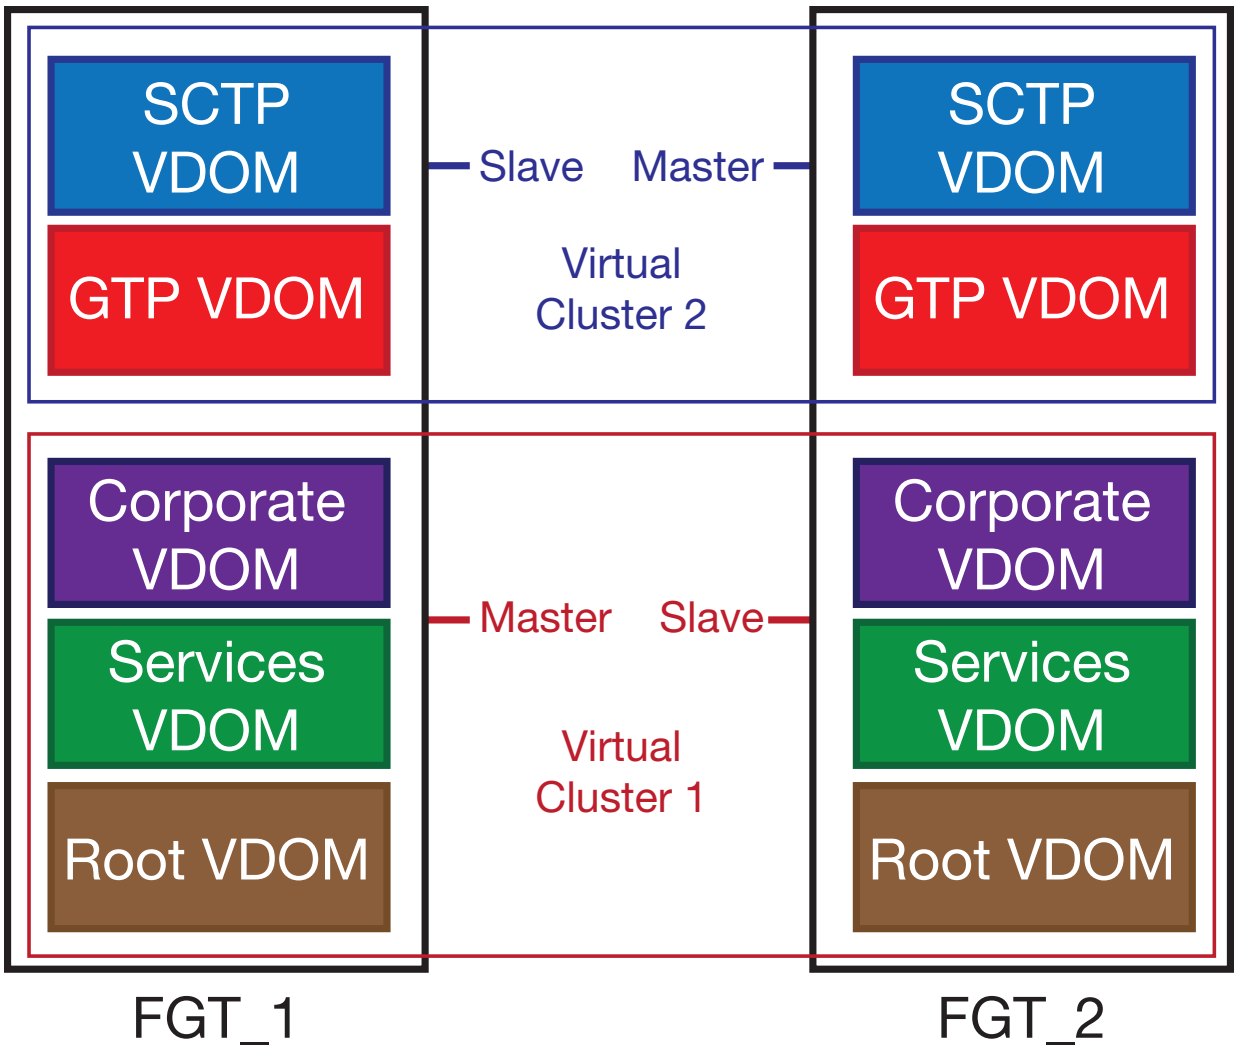


In this example, the firewall layer is configured with two FortiGate devices to act as an HA cluster, providing automatic load balancing and failover detection for the main firewall.

The two devices together make up the firewall, through which all traffic passes. Virtual Domains are created within the FortiGate units, distributing services and traffic into individual VDOMs, allowing them to be monitored and secured individually, to help mitigate possible threats to Carrier networks that target specific services. Individual departments or administrators can manage specific VDOMs, or the FortiGates can be collectively managed centrally by network administrators.

The VDOMs are distributed as shown below:

VDOM distribution between SCTP Firewall Layer FortiGate units



One FortiGate handles basic FortiGate services and non-Carrier traffic. Configuring virtual clustering across the two FortiGates allows one to mirror its VDOMs across to the other unit.

The second FortiGate can then primarily provide Carrier-specific services and handle SCTP, Gi and GTP traffic, using the first FortiGate as the slave unit in a second virtual cluster.

Carrier web-based manager settings

The Carrier menu provides settings for configuring FortiOS Carrier features within the Security Profiles menu. These features include MMS and GTP profiles.

In **Security Profiles > Carrier**, you can configure profiles and settings for MMS and GTP. In the Carrier menu, you can configure an MMS profile and then apply it to a security policy. You can also configure GTP profiles and apply those to security policies as well.

This topic includes the following:

MMS profiles

Since MMS profiles can be used by more than one security policy, you can configure one profile for the traffic types handled by a set of security policies requiring identical protection levels and types, rather than repeatedly configuring those same profile settings for each individual security policy.

If the security policy requires authentication, do not select the MMS profile in the security policy. This type of profile is specific to the authenticating user group. For details on configuring the profile associated with the user group, see User Groups in the Authentication guide.

For example, while traffic between trusted and untrusted networks might need strict protection, traffic between trusted internal addresses might need moderate protection. To provide the different levels of protection, you might configure two separate protection profiles: one for traffic between trusted networks, and one for traffic between trusted and untrusted networks.

Once you have configured the MMS profile, you can then apply the profile to MMS traffic by applying it to a security policy.

MMS profiles can contain settings relevant to many different services. Each security policy uses the subset of the MMS profile settings that apply to the sessions accepted by the security policy. In this way, you might define just one MMS profile that can be used by many security policies, each policy using a different or overlapping subset of the MMS profile.

The MMS Profile page contains options for each of the following:

- MMS scanning
- MMS Bulk Email Filtering Detection
- MMS Address Translation
- MMS Notifications
- DLP Archive
- Logging

MMS profile configuration settings

The following are MMS profile configuration settings in **Security Profiles > MMS Profile**.

MMS Profile page	
Lists each individual MMS profile that you created. On this page, you can edit, delete or create an MMS profile.	
Create New	Creates a new MMS profile. When you select **Create New**, you are automatically redirected to the New MMS Profile page.
Edit	Modifies settings within an MMS profile. When you select **Edit**, you are automatically redirected to the Edit MMS Profile.
Delete	Removes an MMS profile from the list on the MMS Profile page. To remove multiple MMS profiles from within the list, on the MMS Profile page, in each of the rows of the profiles you want removed, select the check box and then select **Delete**. To remove all MMS profiles from the list, on the MMS Profile page, select the check box in the check box column, and then select **Delete**.
Name	The name of the MMS profile.

Ref.	Displays the number of times the object is referenced to other objects. For example, av_1 profile is applied to a security policy; on the Profile page (**Security Profiles > Antivirus**), 1 appears in **Ref.** . To view the location of the referenced object, select the number in **Ref.**, and the Object Usage window appears displaying the various locations of the referenced object. To view more information about how the object is being used, use one of the following icons that is avialable within the Object Usage window: **View the list page for these objects** – automatically redirects you to the list page where the object is referenced at. **Edit this object** – modifies settings within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy and so, when this icon is selected, the user is redirected to the Edit Policy page. **View the details for this object** – table, similar to the log viewer table, contains information about what settings are configured within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy, and that security policy's settings appear within the table.
New MMS Profile page Provides settings for configuring an MMS profile. This page also provides settings for configuring DLP archives and logging.	
Profile Name	Enter a name for the profile.
Comments	Enter a description about the profile. This is optional.
MMS Scanning	Configure MMS Scanning options.
MMS Bulk Email Filtering Detection	Configure MMS Bulk Email options.
MMS Address Translation	Configure MMS Address Translation options.
MMS Notifications	Configure MMS Notification options.
DLP Archive	Configure DLP archive option.
Logging	Configure logging options.

MMS scanning options

You can configure MMS scanning protection profile options to apply virus scanning, file filtering, content filtering, carrier endpoint blocking, and other scanning to MMS messages transmitted using the MM1, MM3, MM4 and

MM7 protocols.

The following are the MMS Scanning options that are available within an MMS profile. You can create an MMS profile in **Security Profiles > MMS Profile** or edit an existing one. You must expand MMS Scanning to access the following options.

MMS Scanning section of the New MMS Profile page	
Monitor Only	Select to cause the unit to record log messages when MMS scanning options find a virus, match a file name, or match content using any of the other MMS scanning options. Select this option to be able to report on viruses and other problems in MMS traffic without affecting users. **Tip:** Select **Remove Blocked** if you want the unit to actually remove content intercepted by MMS scanning options.
Virus Scan	Select to scan attachments in MMS traffic for viruses. Since MM1 and MM7 use HTTP, the oversize limits for HTTP and the HTTP antivirus port configuration also applies to MM1 and MM7 scanning. MM3 and MM4 use SMTP and the oversize limits for SMTP and the SMTP antivirus port configuration also applies to MM3 and MM4 scanning.
Scan MM1 message retrieval	Select to scan message retrievals that use MM1. If you enable **Virus Scan** for all MMS interfaces, messages are also scanned while being sent. In this case, you can disable MM1 message retrieval scanning to improve performance.
Quarantine	Select to quarantine the selected MMS traffic
Remove Blocked	Select to remove blocked content from each protocol and replace it with the replacement message. Select **Constant** if the unit is to preserve the length of the message when removing blocked content, as may occur when billing is affected by the length of the message. **Tip:** If you only want to monitor blocked content, select **Monitor Only**.
Content Filter	Select to filter messages based on matching the content of the message with the words or patterns in the selected web content filter list. For information about adding a web content filter list, see the FortiGate CLI Reference.
Carrier Endpoint Block	Select to add **Carrier Endpoint Filtering** in this MMS profile. Select the carrier endpoint filter list to apply it to the profile.

MMS Scanning section of the New MMS Profile page	
MMS Content Checksum	Select to add MMS Content Checksum in this MMS profile. Select the MMS content checksum list to apply it to the profile.
Pass Fragmented Messages	Select to pass fragmented MM3 and MM4 messages. Fragmented MMS messages cannot be scanned for viruses. If you do not select these options, fragmented MM3 and MM4 message are blocked.
Comfort Clients	Select client comforting for MM1 and MM7 sessions. Since MM1 and MM7 messages use HTTP, MM1 and MM7 client comforting operates like HTTP client comforting.
Comfort Servers	Select server comforting for each protocol. Similar to client comforting, you can use server comforting to prevent server connection timeouts that can occur while waiting for the unit to buffer and scan large POST requests from slow clients.
Interval (1-900 seconds)	Enter the time in seconds before client and server comforting starts after the download has begun, and the time between sending subsequent data.
Amount (1-10240 bytes)	The number of bytes sent by client or server comforting at each interval.
Oversized MMS Message	Select **Block** or **Pass** for files and email messages exceeding configured thresholds for each protocol. The oversize threshold refers to the final size of the message, including attachments, after encoding by the client. Clients can use a variety of encoding types; some result in larger file sizes than the original attachment. As a result, a file may be blocked or logged as oversized even if the attachment is several megabytes smaller than the oversize threshold.
Threshold (1KB - 800 MB)	Enter the oversized file threshold and select KB or MB. If a file is larger than the threshold the file is passed or blocked depending on the ***Oversized MMS Message*** setting. The web-based manager displays the allowed threshold range. The threshold maximum is 10% of the unit's RAM.

MMS bulk email filtering options

You can use the MMS bulk email filtering options to detect and filter MM1 and MM4 message floods and duplicate messages. You can configure three thresholds that define a flood of message activity and three thresholds that define excessive duplicate messages. The configuration of each threshold includes the response actions for the threshold.

The configurable thresholds for each of the flood and duplicate sensors and must be enabled in sequence. For example, you can enable Flood Threshold 1 and Flood Threshold 2, but you cannot disable Flood Threshold 1 and enable Flood Threshold 2.

You can also add MSISDN to the bulk email filtering configuration and select a subset of the bulk email filtering options to applied to these individual MSISDNs.

You must first select MM1 and/or MM4 to detect excessive message duplicates. If excessive message duplicates are detected, the unit will perform the **Duplicate Message Action** for the specified duration.

You can configure three duplicate message thresholds and enable them with separate values and actions. They are labeled Duplicate Threshold 1 through 3 and must be enabled in sequence. For example, you can enable Duplicate Threshold 1 and Duplicate Threshold 2, but you cannot disable Duplicate Threshold 1 and enable Duplicate Threshold 2.

When traffic accepted by a security policy that contains an MMS profile with duplicate message configured receives MM1 or MM4 duplicate messages that match a threshold configured in the MMS protection profile, the unit performs the duplicate message action configured for the matching threshold.

You can configure three message flood thresholds and enable them with separate values and actions. They are labeled Flood Threshold 1 through 3 and must be enabled in sequence. For example, you can enable Flood Threshold 1 and Flood Threshold 2, but you cannot disable Flood Threshold 1 and enable Flood Threshold 2.

When traffic accepted by a security policy that contains an MMS protection profile with message flooding configured experiences MM1 or MM4 message flooding that matches a threshold configured in the MMS profile, the unit performs the message flood action configured for the matching threshold.

MMS Bulk Email Filtering Detection

This section of the New MMS Profile page contains numerous sections where you can configure specific settings for flood threshold, duplicate threshold and recipient MSISDNs.

Message Flood

The message flood settings for each flood threshold. Expand each to configure settings for a threshold.

Flood Threshold 1	Expand to reveal the flood threshold settings for Flood Threshold 1. The settings for Flood Threshold 1 are the same for Flood Threshold 2 and 3.
Enable	Select to apply Flood Threshold 1 to the MSISDN exception.
Message Flood Window	Enter the period of time during which a message flood will be detected if the **Message Flood Limit** is exceeded. The message flood window can be 1 to 2880 minutes (48 hours).
Message Flood Limit	Enter the number of messages which signifies a message flood if exceeded within the **Message Flood Window**.
Message Flood Block Time	Enter the amount of time during which the unit performs the **Message Flood Action** after a message flood is detected.

Message Flood Action	Select one or more actions that the unit is to perform when a message flood is detected.
Flood Threshold 2	Expand to configure settings for Flood Threshold 2 or 3 respectively.
Flood Threshold 3	

Duplicate Message

The duplicate message threshold settings. Expand each to configure settings for a threshold.

MM1 Retrieve Duplicate Enable	Select to scan MM1 `mm1-retr` messages for duplicates. By default, `mm1-retr` messages are not scanned for duplicates as they may often be the same without necessarily being bulk or spam.
Enable	Select to enable the selected duplicate message threshold and to make the rest of the options available for configuration.
Duplicate Message Window	Enter the period of time during which excessive message duplicates will be detected if the Duplicate message Limit it exceeded. The duplicate message window can be 1 to 2880 minutes (48 hours).
Duplicate Message Limit	Enter the number of messages which signifies excessive message duplicates if exceeded within the Duplicate Message Window.
Duplicate Message Block Time	Enter the amount of time during which the unit will perform the Duplicate Message Action after a message flood is detected.
Duplicate Message Action	Select one or more actions that the unit is to perform when excessive message duplication is detected.
Duplicate Threshold 2	Expand to configure settings for Duplicate Threshold 2 or 3 respectively.
Duplicate Threshold 3	

Recipient MSISDN

The recipient Mobile Subscriber Integrated Services Digital Network Number (MSISDN) settings for each recipient MSISDN. When you select **Create New**, you are automatically redirected to the New MSISDN page.

You need to save the profile before you can add MSISDNs.

Recipient MSISDN	The recipient MSISDN.
Flood Threshold 1	Check to enable Flood Threshold 1 settings for this MSISDN.
Flood Threshold 2	ICheck to enable Flood Threshold 2 settings for this MSISDN..
Flood Threshold 3	ICheck to enable Flood Threshold 3 settings for this MSISDN..

Duplicate Threshold 1	Check to enable Duplicate Threshold 1 settings for this MSISDN..
Duplicate Threshold 2	Check to enable Duplicate Threshold 2 settings for this MSISDN..
Duplicate Threshold 3	Check to enable Duplicate Threshold 3 settings for this MSISDN..
Edit	Modifies the settings of a Recipient MSISDN in the Recipient MSISDN list. When you select **Edit**, you are automatically redirected to the New MSISDN page.
Delete	Removes a Recipient MSISDN in the Recipient MSISDN list within the Recipient MSISDN section of the page.
New MSISDN page	
Create New	Creates a new Recipient MSISDN. When you select **Create New**, you are automatically redirected to the New MSISDN page.
Recipient MSISDN	Enter a name for the recipient MSISDN.
Flood Threshold 1	Select to apply Flood Threshold 1 to the MSISDN exception.
Flood Threshold 2	Select to apply Flood Threshold 2 to the MSISDN exception.
Flood Threshold 3	Select to apply Flood Threshold 3 to the MSISDN exception.
Duplicate Threshold 1	Select to apply Duplicate Threshold 1 to the MSISDN exception.
Duplicate Threshold 2	Select to apply Duplicate Threshold 2 to the MSISDN exception.
Duplicate Threshold 3	Select to apply Duplicate Threshold 3 to the MSISDN exception.

MMS Address Translation options

The sender’s carrier endpoint is used to provide logging and reporting details to the mobile operator and to identify the sender of infected content.

When MMS messages are transmitted, the **From** field may or may not contain the sender's address. When the address is not included, the sender information will not be present in the logs and the unit will not be able to notify the user if the message is blocked unless the sender's address is made available elsewhere in the request.

The unit can extract the sender's address from an extended HTTP header field in the HTTP request. This field must be added to the HTTP request before it is received by the unit. If this field is present, it will be used instead of the sender's address in the MMS message for logging and notification. If this header field is present when a message is retrieved, it will be used instead of the **To** address in the message. If this header field is not present the content of the **To** header field is used instead.

Alternatively, the unit can extract the sender’s address from a cookie.

You can configure MMS address translation to extract the sender’s carrier endpoint so that it can be added to log and notification messages. You can configure MMS address translation settings to extract carrier endpoints from HTTP header fields or from cookies. You can also configure MMS address translation to add an endpoint prefix to

the extracted carrier endpoints. For more information, see Dynamic Profiles and Endpoints in the Authentication guide.

MMS Address Translation	
Sender Address Source	Select to extract the sender's address from the **HTTP Header Field** or a **Cookie**. You must also specify the identifier that contains the carrier endpoint.

Sender Address Identifier	Enter the sender address identifier that includes the carrier endpoint. The default identifier is `x-up-calling-line-id`.
	
	If the **Sender Address Source** is **HTTP Header Field**, the address and its identifier in the HTTP request header takes the format:
	
	`<Sender Address Identifier>: <MSISDN_value>`
	
	Where the `<MSISDN_value>` is the carrier endpoint. For example, the HTTP header might contain:
	
	`x-up-calling-line-id: 6044301297`
	
	where `x-up-calling-line-id` would be the Sender Address Identifier.
	
	If the **Sender Address Source** is Cookie, the address and its identifier in the HTTP request header's `Cookie` field takes the format of attribute-value pairs:
	
	`Cookie: id=<cookie-id>;`
	
	`<Sender Address Identifier>=<MSISDN Value>`
	
	For example, the HTTP request headers might contain:
	
	`Cookie: id=0123jf!a;x-up-calling-line-id=6044301297`
	
	where `x-up-calling-line-id` would be the **Sender Address Identifier**.

Convert Sender Address From / To HEX	Select to convert the sender address from ASCII to hexadecimal or from hexadecimal to ASCII. This is required by some applications.
Add Carrier Endpoint Prefix for Logging / Notification	Select the following to enable adding endpoint prefixes for logging and notification.
Enable	Select to enable adding the country code to the extracted carrier endpoint, such as the MSISDN, for logging and notification purposes. You can limit the number length for the test numbers used for internal monitoring without a country code.

MMS Address Translation	
Prefix	Enter a carrier endpoint prefix to be added to all carrier endpoints. Use the prefix to add extra information to the carrier endpoint in the log entry.
Minimum Length	Enter the minimum length of the country code information being added. If this and Maximum Length are set to zero (`0`), length is not limited.
Maximum Length	Enter the maximum length of the country code information being added. If this and Minimum Length are set to zero (`0`), length is not limited.

MMS Notifications

MMS notifications are messages that a unit sends when an MMS profile matches content in an MM1, MM3, MM4 or MM7 session. For example, the MMS profile detects a virus or uses content blocking to block a web page, text message or email. You can send notifications to the sender of the message using same protocol and the addressing headers in the original message. You can also configure MMS notifications to send notification messages to another destination (such as a system administrator) using the MM1, MM3, MM4 or MM7 protocol.

You need to enable one or more **Notification Types** or you can add an **Antivirus Notification List** to enable sending notifications,.

You can also use MMS notifications options to configure how often notifications are sent. The unit sends notification messages immediately for the first event, then at a configurable interval if events continue to occur. If the interval does not coincide with the window of time during which notices may be sent, the unit waits to send the notice in the next available window. Subsequent notices contain a count of the number of events that have occurred since the previous notification.

There are separate notifications for each notification type, including virus events. Virus event notifications include the virus name. Up to three viruses are tracked for each user at a time. If a fourth virus is found, one of the existing tracked viruses is removed from the list.

The notifications are MM1 `m-send-req` messages sent from the unit directly to the MMSC for delivery to the client. The host name of the MMSC, the URL to which `m-send-req` messages are sent, and the port must be specified.

MMS Notification	
Antivirus Notification List	Optionally select an antivirus notification list to select a list of virus names to send notifications for. The unit sends a notification message whenever a virus name or prefix in the antivirus notification list matches the name of a virus detected in a session scanned by the MMS protection profile. Select **Disabled** if you do not want to use a notification list. Instead of selecting a notification list you can configure the **Virus Scan Notification Type** to send notifications for all viruses.

MMS Notification	
Message Protocol	In each column, select the protocol used to send notification messages. You can use a different protocol to send the notification message than the protocol on which the violation was sent. The MMS Notifications options change depending on the message protocol that you select. If you select a different message protocol, you must also enter the User Domain. If selecting MM7 you must also enter the Message Type.
Message Type	Select the MM7 message type to use if sending notifications using MM7. Options include deliver.REQ and submit.REQ
Detect Server Details	Select to use the information in the headers of the original message to set the address of the notification message. If you do not select this option, you can enter the required addressing information manually. You cannot select **Detect Server Details** if you are sending notification messages using a different message protocol. If you select **Detect Server Details**, you cannot change the **Port** where the notification is being sent.
Hostname	Enter the FQDN or the IP address of the server where the notifications will be sent.
URL	Enter the URL of the server. For example if the notificaiton is going to www.example.com/home/alerts , the URL is /home/alerts. This option is available only when **Message Protocol** is **mm1** or **mm7**.
Port	Enter the port number of the server. You cannot change the ***Port*** if ***Detect Server Details*** is enabled.
Username	Enter the user name required for sending messages using this server (optional). This option is available only when **Message Protocol** is **mm7**.
Password	Enter the password required for sending messages using this server (optional). This option is available only when **Message Protocol** is **mm7**.

MMS Notification	
VASP ID	Enter the value-added-service-provider (VASP) ID to be used when sending a notification message. If a VAS is not offered by the mobile provider, it is offered by a third party or a VAS provider or content provider (CP). This option is available only when **Message Protocol** is **mm7**.
VAS ID	Enter the value-added-service (VAS) ID to be used when sending a notification message. A VAS is generally any service beyond voice calls and fax. This option is available only when **Message Protocol** is **mm7**.
All Notification Types	In each column, select notification for all MMS event types for that MMS protocol, then enter the amount of time and select the time unit for notice intervals. Alternatively, expand **All Notification Types**, and then select notification for individual MMS event types for each MMS protocol. Then enter the amount of time and select the time unit for notice intervals. Not all event types are available for all MMS protocols.
Content Filter	In each column, select to notify when messages are blocked by the content filter, then enter the amount of time and select the time unit for notice intervals.
File Block	In each column, select to notify when messages are blocked by file block, then enter the amount of time and select the time unit for notice intervals.
Carrier Endpoint Block	In each column, select to notify when messages are blocked, then enter the amount of time and select the time unit for notice intervals.
Flood	In each column, select to notify when message flood events occur, then enter the amount of time and select the time unit for notice intervals.
Duplicate	In each column, select to notify when duplicate message events occur, then enter the amount of time and select the time unit for notice intervals.
MMS Content Checksum	In each column, select to notify when the content within an MMS message is scanned and banned because of the checksum value that was matched.
Virus Scan	In each column, select to notify when the content within an MMS message is scanned for viruses.

MMS Notification	
Notifications Per Second Limit	For each MMS protocol, enter the number of notifications to send per second. If you enter zero (0), the notification rate is not limited.
Day of Week	For each MMS protocol, select the days of the week the unit is allowed to send notifications.
Window Start Time	For each MMS protocol, select the time of day to begin the message alert window. By default, the message window starts at 00:00. You can change this if you want to start the message window later in the day. When configured, notification outside this window will not be sent.
Window Duration	For each MMS protocol, select the time of day at which to end the message alert window. By default, the message window ends at 00:24. You can change this if you want to end the message window earlier in the day. When configured, notification outside this window will not be sent

DLP Archive options

Select DLP archive options to archive MM1, MM3, MM4, and MM7 sessions. In addition to the MMS profile's DLP archive options, you can:

- Archive MM1 and MM7 message floods
- Archive MM1 and MM7 duplicate messages
- Select **DLP archiving** for carrier endpoint patterns in a **Carrier Endpoint List** and select the **Carrier Endpoint Block** option in the **MMS Scanning** section of an MMS Profile

The unit only allows one sixteenth of its memory for transferring content archive files. For example, for units with 128MB RAM, only 8MB of memory is used when transferring content archive files. Best practices dictate to not enable full content archiving if antivirus scanning is also configured because of these memory constraints.

DLP Archive	
Display DLP meta-information on the system dashboard	Select each required protocol to display the content archive summary in the Log and Archive Statistics dashboard widget on the System Dashboard.

DLP Archive	
Archive to FortiAnalyzer/FortiGuard	Select the type of archiving that you want for the protocol (MM1, MM3, MM4, and MM7). You can choose from Full, Summary or None. **None —** Do not send content archives. **Summary —** Send content archive metadata only. Includes information such as date and time, source and destination, request and response size, and scan result. **Full —** Send content archive both metadata and copies of files or messages. In some cases, FortiOS Carrier may not archive content, or may make only a partial content archive, regardless of your selected option. This behavior varies by prerequisites for each protocol. This option is available only if a FortiAnalyzer unit or FortiGuard Analysis and Management Service is configured.

Logging

You can enable logging in an MMS profile to write event log messages when the MMS profile options that you have enabled perform an action. For example, if you enable MMS antivirus protection, you could also use the MMS profile logging options to write an event log message every time a virus is detected.

You must first configure how the unit stores log messages so that you can then record these logs messages. For more information, see the FortiOS Handbook Logging and Reporting guide.

Logging	
MMS-Antivirus	If antivirus settings are enabled for this MMS profile, select the following options to record **Antivirus Log** messages.
Viruses	Record a log message when this MMS profile detects a virus.
Blocked Files	Record a log message when antivirus file filtering enabled in this MMS profile blocks a file.
Intercepted Files	Record a log message when this MMS profile intercepts a file.
Oversized Files/Emails	Record a log message when this MMS profile encounters an oversized file or email message. Oversized files and email messages cannot be scanned for viruses.
MMS Scanning	If MMS scanning settings are enabled for this MMS profile, select the following options to record **Email Filter Log** messages.
Notification Messages	Select to log the number of MMS notification messages sent.

Logging	
Bulk Messages	Select to log MMS Bulk AntiSpam events. You must also select which protocols to write log messages for in the MMS bulk email filtering part of the MMS profile.
Carrier Endpoint Filter Block	Select to log MMS carrier endpoint filter events, such as MSISDN filtering.
MMS Content Checksum	Select to log MMS content checksum activity.
Content Block	Select to log content blocking events.

MMS Content Checksum

The MMS Content Checksum menu allows you to configure content checksum lists.

Configure MMS content checksum lists in **Security Profiles > MMS Content Checksum** using the following table.

MMS Content Checksum Lists each individual content checksum list that you created. On this page, you can edit, delete or create a content checksum list.	
Create New	Creates a new MMS content checksum list. When you select **Create New**, you are automatically redirected to the New List. This page provides a name field and comment field. You must enter a name to go to MMS Content Checksum Settings page.
Edit	Modifies settings to a MMS content checksum. When you select **Edit**, you are automatically redirected to the MMS Content Checksum Settings page.
Delete	Removes an MMS content checksum from the page. To remove multiple content checksum lists from within the list, on the MMS Content Checksum page, in each of the rows of the content checksum lists you want removed, select the check box and then select **Delete**. To remove all content checksum lists from list, on the MMS Content Checksum page, select the check box in the check box column and then select **Delete**.
Name	The name of the MMS content checksum list that you created.
# Entries	The number of checksums that are included in the content checksum list.

MMS Profiles	The MMS profile or profiles that have the MMS content checksum list applied. For example if two different MMS profiles use this content checksum list, they will both be listed here.
Comments	A description given to the MMS content checksum.
Ref.	Displays the number of times the object is referenced to other objects. For example, av_1 profile is applied to a security policy; on the Profile page (**Security Profiles > AntiVirus > Profiles**), 1 appears in **Ref.** . To view the location of the referenced object, select the number in **Ref.**, and the Object Usage window appears displaying the various locations of the referenced object. To view more information about how the object is being used, use one of the following icons that is avialable within the Object Usage window: • **View the list page for these objects** – automatically redirects you to the list page where the object is referenced at. • **Edit this object** – modifies settings within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy and so, when this icon is selected, the user is redirected to the Edit Policy page. • **View the details for this object** – table, similar to the log viewer table, contains information about what settings are configured within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy, and that security policy's settings appear within the table.

Notification List

The Notification List menu allows you to configure a list of viruses. This virus list provides a list for scanning viruses in MMS messages. You can use one virus list in multiple MMS profiles, and configure multiple virus lists.

Notification list configuration settings

The following are notification list configuration settings in **Security Profiles > Carrier > Notification List**.

Notification List Lists all the notification lists that you created. On this page you can edit, delete or create a new notification list.	
Create New	Creates a new notification list. When you select **Create New**, you are automatically redirected to the New List page. You must enter a name to go to the Notification List Settings page.

Edit	Modifies settings within the notification list. When you select **Edit**, you are automatically redirected to the Notification List Settings page.
Delete	Removes a notification list from the list on the Notification List page. To remove multiple notification lists from within the list, on the Notification List page, in each of the rows of the notification lists you want removed, select the check box and then select **Delete**. To remove all notification lists from the list, on the Notification List page, select the check box in the check box column and then select **Delete**.
Name	The name of the MMS content checksum list that you created.
# Entries	The number of checksums that are included in that content checksum list.
MMS Profiles	The MMS profile or profiles that are associated with
Comments	A description given to the MMS notification list.
Ref.	Displays the number of times the object is referenced to other objects. For example, av_1 profile is applied to a security policy; on the Profile page (**Security Profiles > Antivirus > Profiles**), 1 appears in **Ref.** . To view the location of the referenced object, select the number in **Ref.**, and the Object Usage window appears displaying the various locations of the referenced object. To view more information about how the object is being used, use one of the following icons that is avialable within the Object Usage window: • **View the list page for these objects** – automatically redirects you to the list page where the object is referenced at. • **Edit this object** – modifies settings within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy and so, when this icon is selected, the user is redirected to the Edit Policy page. • **View the details for this object** – table, similar to the log viewer table, contains information about what settings are configured within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy, and that security policy's settings appear within the table.

Notification List Settings

Provides settings for configuring a notification list, which is a list of viruses and is used for scanning viruses in MMS messages. This list is called the Antivirus Notification List in an MMS profile.

Name	If editing the name of a notification list, enter the new name in this field. You must select **OK** to save the change.
Comments	If you want to enter a comment, enter the comment in the field. You must select **OK** to save the change.
Create New	Creates a notification entry in the list. When you select **Create New**, you are automatically redirected to the New Entry page.
Edit	Modifies settings within a notification list. When you select **Edit**, you are automatically redirected to the Edit Entry page.
Delete	Removes a notification entry from the list on the page. To remove multiple notification entries from within the list, on the Notification List Settings page, in each of the rows of the entries you want removed, select the check box and then select **Delete**. To remove all notification entries from the list, on the Notification List Settings page, select the check box in the check box column and then select **Delete**.
Enable	Enables a notification entry that is disabled.
Disable	Disables a notification entry so that it is not active and available for use, but it is not deleted.
Remove All Entries	Removes all notification entries that are listed on the Notification List Settings page.
Enable	Displays whether or not the checksum is enabled.
Virus Name/Profile	The name of the virus that was added to the list.
Entry Type	The type of match that will be used to match the virus stated in the notification list to the actual virus that is found.
New Entry page	
Virus Name/Profile	Enter the virus name.
Entry Type	Select the type of match that will be used to match the virus stated in the notification list to the actual virus that is found.
Enable	Select to enable the virus in the list.

Message Flood

The convenience offered by MM1 and MM4 messaging can be abused by users sending spam or attempting to overload the network with an excess of messages. MMS flood prevention can help prevent this type of abuse. A message flood occurs when a single subscriber sends a volume of messages that exceed the flood threshold that

you set. The threshold defines the maximum number of messages allowed, the period during which the subscriber sent messages are considered, and the length of time the sender is restricted from sending messages after a flood is detected. For example, for the first threshold you may determine that any subscriber who sends more than 100 MM1 messages in an hour (60 minutes) will have all outgoing messages blocked for 30 minutes.

Action		Description
Log		Add a log entry indicating that a message flood has occurred. You must also enable logging for **MMS Scanning > Bulk Messages** in the **Logging** section of the MMS protection profile.
DLP Archive		Save the first message to exceed the flood threshold, or all the messages that exceed the flood threshold, in the DLP archive. DLP archiving flood messages may not always produce useful results. Since different messages can be causing the flood, reviewing the archived messages may not be a good indication of what is causing the problem since the messages could be completely random.
	All messages	All the messages that exceed the flood threshold will be saved in the DLP archive.
	First message only	Save only the first message to exceed the flood threshold in the DLP archive. Other messages in the flood are not saved. For message floods this may not produce much useful information since a legitimate message could trigger the flood threshold.
Intercept		Messages that exceed the flood threshold are passed to the recipients, but if quarantine is enabled for intercepted messages, a copy of each message will also quarantined for later examination. If the quarantine of intercepted messages is disabled, the **Intercept** action has no effect.
Block		Messages that exceed the flood threshold are blocked and will not be delivered to the message recipients. If quarantine is enabled for blocked messages, a copy of each message will quarantined for later examination.
Alert Notification		If the flood threshold is exceeded, the Carrier-enabled FortiGate unit will send an MMS flood notification message. In the web-based manager when **Alert Notification** is selected it displays the fields to configure the notification.

Flood protection for MM1 messages prevents your subscribers from sending too many messages to your MMSC. Configuring flood protection for MM4 messages prevents another service provider from sending too many messages from the same subscriber to your MMSC.

Message flood configuration settings

The following are message flood configuration settings in **Security Profiles > Carrier > Message Flood**.

Message Flood	
Lists the large amount of messages that are being sent to you from outside sources.	
Delete	Removes messages from the list. To remove multiple messages from within the list, on the Message Flood page, in each row of the messages you want removed, select the check box and then select **Delete**. To remove all messages from the list, on the Message Flood page, select the check box in the check box column and then select **Delete**.
Remove All Entries	Removes all messages from the list.
Protocol	The protocol used.
MMS Profile	The MMS profile that is used.
Sender	The sender's email address.
Level	The level of severity of the message.
Count	The count column can be up or down and these settings can be turned off by selecting beside the column's name.
Window Size (minutes)	The time in minutes.
Timer (minutes:seconds)	The time in seconds and in minutes. The timer column can be up or down and these settings turned off by selecting beside the column's name.
Page Controls	Use to navigate through the list.

Duplicate Message

Duplicate message protection for MM1 messages prevents multiple subscribers from sending duplicate messages to your MMSC. Duplicate message protection for MM4 messages prevents another service provider from sending duplicate messages from the same subscriber to your MMSC.

The unit keeps track of the sent messages. If the same message appears more often than the threshold value that you have configured, action is taken. Possible actions are logging the duplicate messages, blocking or intercepting them, archiving, and sending an alert to inform an administrator that duplicate messages are occurring.

Duplicate message configuration settings

View duplicate messages in **Security Profiles > Carrier > Duplicate Message**.

Duplicate Message Lists duplicates of messages that were sent to you.	
Delete	Removes a message from the list. To remove multiple duplicate messages from within the list, on the Message Flood page, in each row of the messages you want removed, select the check box and then select **Delete**. To remove all duplicate messages from the list, on the Message Flood page, select the check box in the check box column and then select **Delete**.
Page Controls	Use to navigate through the list.
Remove All Entries	Removes all duplicate messages from the list.
Protocol	Either MM1 or MM4
Profile	The MMS profile that logs the detection.
Checksum	The checksum of the MMS message.
Status	Either flagged or blank. Flagged means that the actions defined in the MMS profile are taken. For more information, see "MMS bulk email filtering options".
Count	Displays the number of messages in the last window of time.
Window Size (minutes)	The period of time during which a message flood will be detected if the Message Flood Limit is exceeded.
Timer (minutes:seconds)	Either the time left in the window if the message is unflagged, or the time until the message will be unflagged if it is already flagged.

Carrier Endpoint Filter Lists

A carrier endpoint filter list contains carrier endpoint patterns. A pattern can match one carrier endpoint or can use wildcards or regular expressions to match multiple carrier endpoints. For each pattern, you select the action that the unit takes on a message when the pattern matches a carrier endpoint in the message. Actions include blocking the message, exempting the message from MMS scanning, and exempting the message from all scanning. You can also configure the pattern to intercept the message and content archive the message to a FortiAnalyzer unit.

Carrier endpoint filter lists configuration settings

The following are Carrier endpoint filter list configuration settings in **Security Profiles > Carrier Endpoint Filter Lists**.

Carrier Endpoint Filter Lists Lists all the endpoint filters that you created. On this page, you can edit, delete or create a new endpoint filter list.	
Create New	Creates a new endpoint filter list. When you select **Create New**, you are automatically redirected to the New List page. You must enter a name to go to the Carrier Endpoint Filter Lists Settings page.
Edit	Modifies settings within an endpoint filter list in the list.
Delete	Removes an endpoint filter in the list. To remove multiple endpoint filter lists from within the list, on the Carrier Endpoint Filter List page, in each of the rows of the endpoint filter lists you want removed, select the check box and then select **Delete**. To remove all endpoint filter lists from the list, on the Carrier Endpoint Filter List page, select the check box in the check box column and then select **Delete**.
Name	The name of the endpoint filter.
# Entries	The number of carrier endpoint patterns in each carrier endpoint filter list.
MMS Profiles	The MMS profile that the carrier endpoint filter list is added to.
Comments	A description about the endpoint filter.

Ref.	Displays the number of times the object is referenced to other objects. For example, av_1 profile is applied to a security policy; on the Profile page (**Security Profiles > Antivirus > Profiles**), 1 appears in **Ref.** . To view the location of the referenced object, select the number in **Ref.**, and the Object Usage window appears displaying the various locations of the referenced object. To view more information about how the object is being used, use one of the following icons that is avialable within the Object Usage window: • **View the list page for these objects** – automatically redirects you to the list page where the object is referenced at. • **Edit this object** – modifies settings within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy and so, when this icon is selected, the user is redirected to the Edit Policy page. • **View the details for this object** – table, similar to the log viewer table, contains information about what settings are configured within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy, and that security policy's settings appear within the table.

Carrier Endpoint Filter Lists Settings

Provides settings for configuring an endpoint filter.

Name	The name you entered on the New List page, after selecting **Create New** on the Carrier Endpoint Filter page.
Comments	A description about the endpoint filter. You can add one here if you did not enter one on the New List page.
Create New	Creates a new endpoint filter list. When you select **Create New**, you are automatically redirected to the New Entry page.
Edit	Select to modify the settings of a pattern in the list.
Delete	Select to remove a pattern in the list.
Enable	Enables a disabled pattern in the list.
Disable	Disables a pattern in the list.
Remove All Entries	Removes all patterns in the list on the Carrier Endpoint Filter Lists Settings page.
Enable	Indicates whether or not the pattern is enabled.

Pattern	Enter or change the pattern that FortiOS Carrier uses to match with carrier endpoints. The pattern can be a single carrier endpoint or consist of wildcards or Perl regular expressions that will match more than one carrier endpoint. Set **Pattern Type** to correspond to the pattern that you want to use.
Action	Select the action taken by FortiOS Carrier for messages from a carrier endpoint that matches the carrier endpoint pattern:
Pattern Type	The type of pattern chosen.
New Entry page	
Pattern	Enter or change the pattern that FortiOS Carrier uses to match with carrier endpoints. The pattern can be a single carrier endpoint or consist of wildcards or Perl regular expressions that will match more than one carrier endpoint. Set **Pattern Type** to correspond to the pattern that you want to use.
Action(s)	Select the action taken by FortiOS Carrier for messages from a carrier endpoint that matches the carrier endpoint pattern:
Content Archive	MMS messages from the carrier endpoint are delivered, the message content is DLP archived according to MMS DLP archive settings. Content archiving is also called DLP archiving.
Intercept	MMS messages from the carrier endpoint are delivered. Based on the quarantine configuration, attached files may be removed and quarantined.
Pattern Type	Select a pattern type as one of Single Carrier Endpoint, Wildcard or Regular Expression. Wildcard and Regular Expression will match multiple patterns where Signle Carrier Endpoint matches only one.
Enable	Select to enable this carrier endpoint filter pattern.

GTP Profile

You can configure multiple GTP profiles within the GTP menu. GTP profiles concern GTP activity flowing through the unit. These GTP profiles are then applied to a security policy.

GTP profile configuration settings

The following are GTP profile configuration settings in **Security Profiles > GTP Profile**.

GTP Profile Lists each GTP profile that you have created. On this page, you can edit, delete or create a new GTP profile.

Create New	Creates a new GTP profile. When you select **Create New**, you are automatically redirected to the New page.
Edit	Modifies settings within a GTP profile in the list. When you select **Edit**, you are automatically redirected to Edit page.
Delete	Removes a GTP profile from the list. To remove multiple GTP profiles from within the list, on the GTP Profile page, in each of the rows of the profiles you want removed, select the check box and then select **Delete**. To remove all GTP profiles from within the list, on the GTP Profile page, select the check box in the check box column and then select **Delete**.
Name	The name of the GTP profile.
Ref.	Displays the number of times the object is referenced to other objects. For example, av_1 profile is applied to a security policy; on the Profile page (**Security Profiles > Antivirus > Profiles**), 1 appears in **Ref.** . To view the location of the referenced object, select the number in **Ref.**, and the Object Usage window appears displaying the various locations of the referenced object. To view more information about how the object is being used, use one of the following icons that is avialable within the Object Usage window: • **View the list page for these objects** – automatically redirects you to the list page where the object is referenced at. • **Edit this object** – modifies settings within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy and so, when this icon is selected, the user is redirected to the Edit Policy page. • **View the details for this object** – table, similar to the log viewer table, contains information about what settings are configured within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy, and that security policy's settings appear within the table.
New GTP Profile Provides settings for configuring a GTP profile.	
Name	Enter a name for the GTP profile.
General Settings	Configure general options for the GTP profile..

Message Type Filtering	Configure filtering for messages.
APN Filtering	Configure filtering options for APN.
IMSI Filtering	Configure filtering options for IMSI.
Advanced Filtering	Configure advanced filtering options.
IE removal policy	Configure IE removal policy options.
Encapsulated IP Traffic Filtering	Configure filtering options for encapsulated IP traffic.
Encapsulated Non-IP End User Address Filtering	Configure filtering options for encapsulated non-IP end user addresses.
Protocol Anomaly	Configure protocol anomaly options.
Anti-Overbilling	Configure anti-overbilling options.
Log	Configure log options.

General settings options

The following are mostly house keeping options that appear in the General Settings area of the GTP configuration page.

General Settings section of the New GTP Profile	
Sequence Number Validation	Enable to check that packets are not duplicated or out of order. GTP packets contain a Sequence Number field. This number tells the receiving GGSN the order of the packets it is receiving. Normally the GGSN compares this sequence number in the packets with its own sequence counter — if the two do not match, the packet is dropped. This sequence number validation can be off-loaded to the FortiOS Carrier freeing up resources on the GGSN.
GTP-in-GTP	Select **Allow** to enable GTP packets to be allowed to contain GTP packets, or a GTP tunnel inside another GTP tunnel. To block all GTP-in-GTP packets, select **Deny**.
Minimum Message Length	Enter the shortest possible message length in bytes. Normally this is controlled by the protocol, and will vary for different message types. If a packet is smaller than this limit, it is discarded as it is likely malformed and a potential security risk. The default minimum message length is 0 bytes.

General Settings section of the New GTP Profile	
Maximum Message Length	Enter the maximum allowed length of a GTP packet in bytes. A GTP packet contains three headers and corresponding parts GTP, UDP, and IP. If a packet is larger than the maximum transmission unit (MTU) size, it is fragmented to be delivered in multiple packets. This is inefficient, resource intensive, and may cause problems with some applications. By default the maximum message length is 1452 bytes.
Tunnel Limit	Enter the maximum number of tunnels allowed open at one time. For additional GTP tunnels to be opened, existing tunnels must first be closed. This feature can help prevent a form of denial of service attack on your network. This attack involves opening more tunnels than the network can handle and consuming all the network resources doing so. By limiting the number of tunnels at any one time, this form of attack will be avoided. The tunnel limiting applies to the Handover Group, and Authorized SGSNs and GGSNs.
Tunnel Timeout	Enter the maximum number of seconds that a GTP tunnel is allowed to remain active. After the timeout the unit deletes GTP tunnels that have stopped processing data. A GTP tunnel may hang for various reasons. For example, during the GTP tunnel tear-down stage, the "delete pdap context response" message may get lost. By setting a timeout value, you can configure the FortiOS Carrier firewall to remove the hanging tunnels. The default is 86400 seconds, or 24 hours.
Control plane message rate limit	Enter the number of packets per second to limit the traffic rate to protect the GSNs from possible Denial of Service (DoS) attacks. The default limit of **0** does not limit the message rate. GTP DoS attacks can include: • **Border gateway bandwidth saturation**: A malicious operator can connect to your GRX and generate high traffic towards your Border Gateway to consume all the bandwidth. • **GTP flood**: A GSN can be flooded by illegitimate traffic

General Settings section of the New GTP Profile	
Handover Group	Select the allowed list of IP addresses allowed to take over a GTP session when the mobile device moves locations. Handover is a fundamental feature of GPRS/UMTS, which enables subscribers to seamlessly move from one area of coverage to another with no interruption of active sessions. Session hijacking can come from the SGSN or the GGSN, where a fraudulent GSN can intercept another GSN and redirect traffic to it. This can be exploited to hijack GTP tunnels or cause a denial of service. When the handover group is defined it acts like a whitelist with an implicit default deny at the end — the GTP address must be in the group or the GTP message will be blocked. This stops handover requests from untrusted GSNs.
Authorized SGSNs	Use **Authorized SGSNs** to only allow authorized SGSNs to send packets through the unit and to block unauthorized SGSNs. Go to **Firewall Objects > Address > Addresses** and add the IP addresses of the authorized SGSNs to a firewall address or address group. Then set **Authorized SGSNs** to this firewall address or address group. You can use **Authorized SGSNs** to allow packets from SGSNs that have a roaming agreement with your organization.
Authorized GGSNs	Use **Authorized GGSNs** to only allow authorized GGSNs to send packets through the unit and to block unauthorized GGSNs. Go to **Firewall Objects > Address > Addresses** and add the IP addresses of the authorized GGSNs to a firewall address or address group. Then set **Authorized GGSNs** to this firewall address or address group. You can use Authorized GGSNs to allow packets from SGSNs that have a roaming agreement with your organization.

Message type filtering options

On the **New GTP Profile** page, you can select to allow or deny the different types of GTP messages, which is referred to as message type filtering. You must expand the Message Type Filtering section to access the settings.

The messages types include Path Management, Tunnel Management, Location Management, Mobility Management, MBMS, and GTP-U and Charging Management messages.

For enhanced security, Fortinet best practices dictate that you set Unknown Message Action to deny. This will block all unknown GTP message types, some of which may be malicious.

To configure message type filter options, expand **Message Type Filtering** in the GTP profile.

APN filtering options

An Access Point Name (APN) is an Information Element (IE) included in the header of a GTP packet. It provides information on how to reach a network.

An APN has the following format:

```
<network_id>[.mnc<mnc_int>.mcc<mcc_int>.gprs]
```

Where:

- `<network_id>` is a network identifier or name that identifies the name of a network, for example, `example.com` or `internet`.
- `[.mnc<mnc_int>.mcc<mcc_int>.gprs]` is the optional operator identifier that uniquely identifies the operator's PLMN, for example `mnc123.mcc456.gprs`.

Combining these two examples results in a complete APN of `internet.mnc123.mcc456.gprs`.

By default, the unit permits all APNs. However, you can configure APN filtering to restrict roaming subscribers' access to external networks.

APN filtering applies only to the GTP **create pdp request** messages. The unit inspects GTP packets for both APN and selected modes. If both parameters match and APN filter entry, the unit applies the filter to the traffic.

Additionally, the unit can filter GTP packets based on the combination of an IMSI prefix and an APN.

You cannot add an APN when creating a new profile.

APN Filtering	
Enable APN Filter	Select to enable APN filtering.
Default APN Action	Select the default action for APN filtering. If you select **Allow**, all sessions are allowed except those blocked by individual APN filters. If you select **Deny**, all sessions are blocked except those allowed by individual APN filters.
Value	The APN to be filtered.
Mode	The type of mode chosen that indicates where the APN originated and whether the Home Location Register (HLR) has verified the user subscription:
Action	The type of action that will be taken.
Edit	Modifies the settings within the filter. When you select **Edit**, the Edit window appears, which allows you to modify the settings of the APN.
Delete	Removes the APN from the list within the table, in the APN Filtering section.

Add APN	Adds a new APN filter to the list. When you select **Add APN**, the New window appears, which allows you to configure the APN settings.
New APN page	
Value	Enter an APN to be filtered. You can include wild cards to match multiple APNs. For example, the value **internet*** would match all APNs that being with **internet**.
Mode	Select one or more of the available modes to indicate where the APN originated and whether the Home Location Register (HLR) has verified the user subscription.
Mobile Station provided	MS-provided APN, subscription not verified, indicates that the mobile station (MS) provided the APN and that the HLR did not verify the user's subscription to the network.
Network provided	Network-provided APN, subscription not verified, indicates that the network provided a default APN because the MS did not specify one, and that the HLR did not verify the user's subscription to the network.
Subscription Verified	MS or Network-provided APN, subscription verified, indicates that the MS or the network provided the APN and that the HLR verified the user's subscription to the network
Action	Select **Allow** or **Deny**.

Basic filtering options

The International Mobile Station Identity (IMSI) is used by a GPRS Support Node (GSN) to identify a mobile station. Three elements make up every IMSI:

- the mobile country code (MCC)
- the mobile network code (MNC)
- the mobile subscriber identification number (MSIN).

The subscriber's home network—the public land mobile network (PLMN)—is identified by the IMSI prefix, formed by combining the MCC and MNC.

By default, the unit allows all IMSIs. You can add IMSI prefixes to deny GTP traffic coming from non-roaming partners. Any GTP packets with IMSI prefixes not matching the prefixes you set will be dropped. GTP **Create pdp** request messages are filtered and only IMSI prefixes matching the ones you set are permitted. Each GTP profile can have up to 1000 IMSI prefixes set.

An IMSI prefix and an APN can be used together to filter GTP packets if you set an IMSI filter entry with a non-empty APN.

You cannot add an IMSI when creating a new profile. You must add it after the profile has been created and you are editing the profile.

IMSI Filtering section of the New GTP Profile	
Enable IMSI Filter	Select to enable IMSI filtering.
Default IMSI Action	Select the default action for IMSI filtering. If you select **Allow**, all sessions are allowed except those blocked by individual IMSI filters. If you select **Deny**, all sessions are blocked except those allowed by individual IMSI filters.
APN	The APN that is part of the IMSI that will be filtered.
MCC-MNC	The MCC-MNC part of the IMSI that will be filtered.
Mode	The type of mode that indicates where the APN originated and whether the Home Location Register (HLR) has verified the user subscription.
Action	The type of action that will be taken.
Edit	Modifies settings to an IMSI filter. When you select **Edit**, the Edit window appears, which allows you to modify the IMSI filter's settings.
Delete	Removes an IMSI filter from within the table, in the IMSI Filtering section.
Add IMSI	Adds a new IMSI filter to the list. When you select **Add IMSI**, the New window appears, which allows you to configure IMSI filter settings.
New IMSI page	
APN	Enter the APN part of the IMSI to be filtered.
MCC-MNC	Enter the MCC-MCC part of the IMSI to be filtered.
Mode	Select one or more of the available modes to indicate where the APN originated and whether the Home Location Register (HLR) has verified the user subscription.
Mobile Station provided	MS-provided APN, subscription not verified, indicates that the mobile station (MS) provided the APN and that the HLR did not verify the user's subscription to the network.
Network provided	Network-provided APN, subscription not verified, indicates that the network provided a default APN because the MS did not specify one, and that the HLR did not verify the user's subscription to the network.
Subscription Verified	MS or Network-provided APN, subscription verified, indicates that the MS or the network provided the APN and that the HLR verified the user's subscription to the network
Action	Select **Allow** or **Deny**.

Advanced filtering options

The FortiOS Carrier firewall supports advanced filtering against the attributes RAT, RAI, ULI, APN restriction, and IMEI-SV in GTP to block specific harmful GPRS traffic and GPRS roaming traffic. The following table shows some of the GTP context requests and responses that the firewall supports.

Attributes supported by FortiCarrier firewalls

	GTP Create PDP Context Request	GTP Create PDP Context Response	GTP Update PDP Context Request	GTP Update PDP Context Response
APN	yes	yes	-	
APN Restriction	yes	-	-	yes
IMEI-SV	yes	-	-	-
IMSI	yes	-	yes	-
RAI	yes	-	yes	-
RAT	yes	-	yes	-
ULI	yes	-	yes	-

When editing a GTP profile, select **Advanced Filtering > Add** to create and add a rule. When the rule matches traffic it will either allow or deny that traffic as selected in the rule.

Advanced Filtering	
Enable	Select to enable advanced filtering.
Default Action	Select the default action for advanced filtering. If you select **Allow**, all sessions are allowed except those blocked by individual advanced filters. If you select **Deny**, all sessions are blocked except those allowed by individual advanced filters.
Messages	The messages, for example, Create PDP Context Request.
APN Restriction	The APN restriction.
RAT Type	The RAT types associated with that filter.
ULI	The ULI pattern.
RAI	The RAI pattern.

IMEI	The IMEI pattern.
Action	The action that will be taken.
Edit	Modifies the filter's settings. When you select **Edit**, the Edit window appears, which allows you to modify the filter's settings.
Delete	Removes a filter from the list.
Add	Adds a filter to the list. When you select **Add**, the New window appears, which allows you to configure settings for messages, APN, IMSI, MSISDN, RAT type, ULI, RAI, IMEI patterns as well as the type of action.
New Filtering page	
Messages	The PDP content messages this profile will match.
Create PDP Context Request	Select to allow create PDP context requests.
Create PDP Context Response	Select to allow create PDP context responses.
Update PDP Context Request	Select to allow update PDP context requests.
Update PDP Context Response	Select to allow update PDP context responses.
APN	Enter the APN.
APN Mode	Select an APN mode as one or more of • Mobile Station provied • Network provided • Subscription provied This field is only available when an APN has been entered.
Mobile Station provided	MS-provided PAN, subscription not verified, indicates that the mobile station (MS) provided the APN and that the HLR did not verify the user's subscription to the network.
Network provided	Network-provided APN, subscription not verified, indicates that the network provided a default APN because the MS did not specify one, and that the HLR did no verify the user's subscription to the network.

Subscription verified	MS or Network-provided APN, subscription verified, indicates that the MS or the network provided the APN and that the HLR verified the user's subscription to the network.
APN Restriction	Select the type of restriction that you want. You can choose all of the types, or one of the types. You cannot choose multiple types. Types include: • all • Public-1 • Public-2 • Private-1 • Private-2
IMSI	Enter the IMSI.
MSISDN	Enter the MSISDN.
RAT Type	Optionally select the RAT type as any combination of the following: • Any • UTRAN • GERAN • Wifi • GAN • HSPA Some RAT types are GTPv1 specific.
ULI pattern	Enter the ULI pattern.
RAI pattern	Enter the RAI pattern.
IMEI pattern	Enter the IMEI pattern.
Action	Select either **Allow** or **Deny**.

Adding an advanced filtering rule

When adding a rule, use the following formats:

- Prefix, for example, range 31* for MCC matches MCC from 310 to 319.
- Range, for example, range 310-319 for MCC matches MCC from 310 to 319.
- Mobile Country Code (MCC) consists of three digits. The MCC identifies the country of domicile of the mobile subscriber.
- Mobile Network Code (MNC) consists of two or three digits for GSM/UMTS applications. The MNC identifies the home PLMN of the mobile subscriber. The length of the MNC (two or three digits) depends on the value of the MCC. Best practices dictate not to mix two and three digit MNC codes within a single MCC area.
- Location Area Code (LAC) is a fixed length code (of 2 octets) identifying a location area within a PLMN. This part of the location area identification can be coded using a full hexadecimal representation except for the following

reserved hexadecimal values: 0000 and FFFE. These reserved values are used in some special cases when no valid LAI exists in the MS (see 3GPP TS 24.008, 3GPP TS 31.102 and 3GPP TS 51.011).

- Routing Area Code (RAC) of a fixed length code (of 1 octet) identifies a routing area within a location.
- CI or SAC of a fixed length of 2 octets can be coded using a full hexadecimal expression.
- Type Allocation Code (TAC) has a length of 8 digits.
- Serial Number (SNR) is an individual serial number identifying each equipment within each TAC. SNR has a length of 6 digits.
- Software Version Number (SVN) identifies the software version number of the mobile equipment. SVN has a length of 2 digits.

You cannot add an advanced filtering rule when creating a new profile. You must add it after the profile has been created and you are editing the profile.

Information Element (IE) removal policy options

In some roaming scenarios, the unit is installed on the border of the PLMN and the GRX. In this configuration, the unit supports information element (IE) removal policies to remove any combination of R6 IEs (RAT, RAI, ULI, IMEI-SV and APN restrictions) from the types of messages described in "Advanced filtering options", prior to forwarding the messages to the HGGSN (proxy mode).

IE removal policy	
Enable	Select to enable this option.
SGSN address of message IE	The firewall address or address group that contains the SGSN addresses.
IEs to be removed	The IE types that will be removed. These include APN Restriction, RAT, RAI, ULI, and IMEI.
Add	Adds an IE removal policy. When you select **Add**, the New window appears, which allows you to configure the IE policy.
Edit	Modifies settings from within the IE removal policy. When you select **Edit**, the Edit window appears, which allows you to modify the settings within the policy.
Delete	Removes the IE removal policy from the list.
New IE policy page	
SGSN address	Select a firewall address or address group that contains SGSN addresses.
IEs to be removed	Select one or more IE types to be removed. These include APN Restriction, RAT, RAI, ULI, and IMEI.

Encapsulated IP traffic filtering options

You can use encapsulated IP traffic filtering to filter GTP sessions based on information contained in the data stream. to control data flows within your infrastructure. You can configure IP filtering rules to filter encapsulated IP traffic from mobile stations by identifying the source and destination policies. For more information, see When to use encapsulated IP traffic filtering.

Expand **Encapsulated IP Traffic Filtering** in the GTP profile to reveal the options.

Encapsulated IP Traffic Filtering	
Enable IP Filter	Select to enable encapsulated IP traffic filtering options.
Default IP Action	Select the default action for encapsulated IP traffic filtering. If you select **Allow**, all sessions are allowed except those blocked by individual encapsulated IP traffic filters. If you select **Deny**, all sessions are blocked except those allowed by individual encapsulated IP traffic filters.
Source	Select a source IP address from the configured firewall IP address or address group lists. Any encapsulated traffic originating from this IP address will be a match if the destination also matches.
Destination	Select a destination IP address from the configured firewall IP address or address group lists. Any encapsulated traffic being sent to this IP address will be a match if the destination also matches.
Action	The type of action that will be taken. Select to **Allow** or **Deny** encapsulated traffic between this source and Destination.
Edit	Modifies the source, destination or action settings.
Add IP Policy	Adds a new encapsulated IP traffic filter. When you select **Add IP Policy**, the New window appears which allows you to configure IP policy settings.
New (window)	
Source	Select the source firewall address or address group.
Destination	Select the destination firewall address or address group.
Action	Select **Allow** or **Deny**.

Encapsulated non-IP end user traffic filtering options

Depending on the installed environment, it may be beneficial to detect GTP packets that encapsulate non-IP based protocols. You can configure the FortiOS Carrier firewall to permit a list of acceptable protocols, with all other protocols denied.

The encoded protocol is determined in the PDP Type Organization and PDP Type Number fields within the End User Address Information Element. The PDP Type Organization is a 4-bit field that determines if the protocol is part of the ETSI or IETF organizations. Values are zero and one, respectively. The PDP Type field is one byte long. Both GTP specifications list only PPP, with a PDP Type value of one, as a valid ETSI protocol. PDP Types for the IETF values are determined in the “Assigned PPP DLL Protocol Numbers” sections of RFC1700. The PDP types are compressed, meaning that the most significant byte is skipped, limiting the protocols listed from 0x00 to 0xFF.

Encapsulated Non-IP End User Address Filtering	
Enable Non-IP Filter	Select to enable encapsulated non-IP traffic filtering.
Default Non-IP Action	Select the default action for encapsulated non-IP traffic filtering. If you select **Allow**, all sessions are allowed except those blocked by individual encapsulated non-IP traffic filters. If you select **Deny**, all sessions are blocked except those allowed by individual encapsulated non-IP traffic filters.
Type	The type chosen, **AESTI** or **IETF.**
Start Protocol	The beginning protocol port number range.
End Protocol	The end of the protocol port number range.
Action	The type of action that will be taken.
Edit	Modify a non-IP filter's settings in the list. When you select **Edit**, the Edit window appears, which allows you to modify the Non-IP policy settings.
Delete	Remove a non-IP policy from the list.
Add Non-IP Policy	Add a new encapsulated non-IP traffic filter. When you select **Add Non-IP Policy**, you are automatically redirected to the New page.
New (window)	
Type	Select **AESTI** or **IETF**.
Start Protocol **End Protocol**	Select a start and end protocol from the list of protocols in RFC 1700. Allowed range includes 0 to 255 (0x00 to 0xff). Some common protocols include: • 33 (0x0021) Internet Protocol • 35 (0x0023) OSI Network Layer • 63 (0x003f) NETBIOS Framing • 65 (0x0041) Cisco Systems • 79 (0x004f) IP6 Header Compression • 83 (0x0053) Encryption
Action	Select **Allow** or **Deny**.

Protocol Anomaly prevention options

Use protocol anomaly detection options to detect or deny protocol anomalies according to GTP standards and tunnel state. Protocol anomaly attacks involve malformed or corrupt packets that typically fall outside of the protocol specifications. Packets cannot pass through if they fail the sanity check.

Protocol Anomaly	
Invalid Reserved Field	GTP version 0 (GSM 09.60) headers specify a number of fields that are marked as "Spare" and contain all ones (1). GTP packets that have different values in these fields are flagged as anomalies. GTP version 1 (GSM 29.060) makes better use of the header space and only has one, 1-bit, reserved field. In the first octet of the GTP version1 header, bit 4 is set to zero.
Reserved IE	Both versions of GTP allow up to 255 different Information Elements (IE). However, a number of Information Elements values are undefined or reserved. Packets with reserved or undefined values will be filtered.
Miss Mandatory IE	GTP packets with missing mandatory Information Elements (IE) will not be passed to the GGSN.
Out of State Message	The GTP protocol requires a certain level of state to be kept by both the GGSN and SGSN. Some message types can only be sent when in a specific GTP state. Packets that do not make sense in the current state are filtered or rejected Both versions of GTP allow up to 255 different message types. However, a number of message type values are undefined or reserved. Best practices dictate that packets with reserved or undefined values will be filtered.
Out of State IE	GTP Packets with out of order Information Elements are discarded.
Spoofed Source Address	The End User Address Information Element in the PDP Context Create & Response messages contain the address that the mobile station (MS) will use on the remote network. If the MS does not have an address, the SGSN will set the End User Address field to zero when sending the initial PDP Context Create message. The PDP Context Response packet from the GGSN will then contain an address to be assigned to the MS. In environments where static addresses are allowed, the MS will relay its address to the SGSN, which will include the address in the PDP Context Create Message. As the MS address is negotiated within the PDP Context creation handshake, any packets originating from the MS that contain a different source address are detected and dropped.

Anti-Overbilling options

You can configure the FortiOS Carrier firewall to prevent overbilling subscribers for traffic over the. To enable anti-overbilling, you must configure both the Gn/Gp firewall and the Gi firewall.

Expand **Anti-Overbilling** in the GTP profile to reveal these settings.

Anti-Overbilling	
Gi Firewall IP Address	The IP address of the unit's interface configured as a Gi gateway.
Port	The SG security port number. The default port number is port 21123. Change this number if your system uses a different SG port.
Interface	Select the unit interface configured as a Gi gateway.
Security Context ID	Enter the security context ID. This ID must match the ID entered on the server Gi firewall. The default security context ID is 696.

Log options

All the GTP logs are treated as a subtype of the event logs. To enable GTP logging, you must:

- configure the GTP log settings in a GTP profile
- enable GTP logging when you configure log and report settings.

To enable GTP logging after a GTP profile has been configured

1. Go to **Log & Report > Log Settings**.
2. Select **Event Logging**, and select **GTP service event**.
3. Select **Apply**.

Log	
Log Frequency	Enter the number of messages to drop between logged messages. An overflow of log messages can sometimes occur when logging rate-limited GTP packets exceed their defined threshold. To conserve resources on the syslog server and the Carrier-enabled FortiGate unit, you can specify that some log messages are dropped. For example, if you want only every twentieth message to be logged, set a logging frequency of 20. This way, 20 messages are skipped and the next logged. Acceptable frequency values range from 0 to 2147483674. When set to '0', no messages are skipped.
Forwarded Log	Select to log forwarded GTP packets.
Denied Log	Select to log GTP packets denied or blocked by this GTP profile.
Rate Limited Log	Select to log rate-limited GTP packets.
State Invalid Log	Select to log GTP packets that have failed stateful inspection.
Tunnel Limit Log	Select to log packets dropped because the maximum limit of GTP tunnels for the destination GSN is reached.

Extension Log	Select to log extended information about GTP packets. When enabled, this additional information will be included in log entries: • IMSI • MSISDN • APN • Selection Mode • SGSN address for signaling • SGSN address for user data • GGSN address for signaling • GGSN address for user data
Traffic count Log	Select to log the total number of control and user data messages received from and forwarded to the GGSNs and SGSNs that the unit protects. The unit can report the total number of user data and control messages received from and forwarded to the GGSNs and SGSNs it protects. Alternately, the total size of the user data and control messages can be reported in bytes. The unit differentiates between traffic carried by each GTP tunnel, and also between GTP-User and GTP-Control messages. The number of messages or the number of bytes of data received from and forwarded to the SGSN or GGSN are totaled and logged if a tunnel is deleted. When a tunnel is deleted, the log entry contains: • Timestamp • Interface name (if applicable) • SGSN IP address • GGSN IP address • TID • Tunnel duration time in seconds • Number of messages sent to the SGSN • Number of messages sent to the GGSN

Specifying logging types

You can configure the unit to log GTP packets based on their status with GTP traffic logging.

The status of a GTP packet can be any of the following 5 states:

- **Forwarded** - a packet that the unit transmits because the GTP policy allows it
- **Prohibited** - a packet that the unit drops because the GTP policy denies it
- **Rate-limited** - a packet that the unit drops because it exceeds the maximum rate limit of the destination GSN
- **State-invalid** - a packet that the unit drops because it failed stateful inspection
- **Tunnel-limited** - a packet that the unit drops because the maximum limit of GTP tunnels for the destination GSN is reached.

The following information is contained in each log entry:

- Timestamp
- Source IP address

- Destination IP address
- Tunnel Identifier (TID) or Tunnel Endpoint Identifier (TEID)
- Message type
- Packet status: forwarded, prohibited, state-invalid, rate-limited, or tunnel-limited
- Virtual domain ID or name
- Reason to be denied if applicable.

MMS Security features

FortiOS Carrier includes all the Security features of FortiOS with extra features specific to MMS carrier networks.

This section includes:

Why scan MMS messages for viruses and malware?

The requirement for scanning MM1 content comes from the fact that MMS is an increasingly popular technique for propagating malware between mobile devices.

Example: COMMWARRIOR

This is a virus for Series 60 type cell phones, such as Nokia, operating Symbian OS version 6 [or higher]. The object of the virus is to spread to other phones using Bluetooth and MMS as transport avenues. The targets are selected from the contact list of the infected phone and also sought via Bluetooth searching for other Bluetooth-enabled devices (phones, printers, gaming devices etc.) in the proximity of the infected phone.

This virus is more than a proof of concept - it has proven successfully its ability to migrate from a zoo collection to being in-the-wild. Currently, this virus is being reported in over 18 different countries around Europe, Asia and North America.

When the virus first infects a cell phone, a prompt is displayed asking the recipient if they want to install “Caribe”. Symptoms of an infected phone may include rapid battery power loss due to constant efforts by the virus to spread to other phones via a Bluetooth seek-and-connect outreach.

The following variants among others are currently scanned by the FortiOS Carrier devices, in addition to more signatures that cover all known threats.

- **SymbOS/COMWAR.V10B!WORM**
- Aliases: SymbOS.Commwarrior.B, SymbOS/Commwar.B, SymbOS/Commwar.B!wm, SymbOS/Commwar.B-net, SymbOS/Commwarrior.b!sis, SymbOS/Comwar.B, SymbOS/Comwar.B!wm, SymbOS/Comwar.B-wm, SYMBOS_COMWAR.B, SymbOS/Comwar.1.0.B!wormSYMBOS/COMWAR.V10B.SP!WORM [spanish version]
- First Discovered In The Wild: July 04, 2007
- Impact Level: 1
- Virus Class: Worm
- Virus Name Size: 23,320
- **SymbOS/Commwar.A!worm**
- Aliases: Commwarrior-A, SymbOS.Commwarrior.A [NAV], SymbOS/Commwar.A-net, SymbOS/Commwar_ezboot.A-ne, SymbOS/Comwar.A, SymbOS/Comwar.A-wm, SYMBOS_COMWAR.A [Trend]
- First Discovered In The Wild: May 16 2005
- Impact Level: 1
- Virus Class: Worm
- Virus Name Size: 27,936
- SymbOS/Commwarriie.C-wm
- Aliases: None
- First Discovered In The Wild: Oct 17 2005

- Impact Level: 1
- Virus Class: File Virus
- Virus Name Size: None

For the latest list of threats Fortinet devices detect, visit the FortiGuard Center.

MMS virus scanning

You can use MMS virus scanning to scan content contained within MMS messages for viruses. FortiOS Carrier virus scanning can be applied to the MM1, MM3, MM4, and MM7 interfaces to detect and remove content containing viruses at many points in an MMS network. Perhaps the most useful interface to apply virus scanning would be the MM1 interface to block viruses sent by mobile users before they get into the service provider network.

To go to MMS virus scanning, go to **Security Profiles MMS Profile**, select an existing or create a new profile, and expand **MMS Scanning**. See MMS scanning options.

This section includes:

- MMS virus monitoring
- MMS virus scanning blocks messages (not just attachments)
- Scanning MM1 retrieval messages
- Configuring MMS virus scanning
- Removing or replacing blocked messages
- Carrier Endpoint Block
- MMS Content Checksum
- Passing or blocking fragmented messages
- Client comforting
- Server comforting
- Handling oversized MMS messages

MMS virus monitoring

To enable MMS virus monitoring, expand **MMS Scanning** and enable **Monitor only** for the selected MMS types.

This feature causes the FortiOS Carrier unit to record log messages when MMS scanning options find a virus, match a file name, or match content using any of the other MMS scanning options. Selecting this option enables reporting on viruses and other problems in MMS traffic without affecting users.

MMS virus scanning blocks messages (not just attachments)

To enable MMS virus scanning, expand **MMS Scanning** and enable **Virus Scan** for the selected MMS types.

Because MM1 and MM7 use HTTP, the oversize limits for HTTP and the HTTP antivirus port configurations also apply to MM1 and MM7 scanning. See

MM3 and MM4 use SMTP and the oversize limits for SMTP and the SMTP antivirus port configurations also apply to MM3 and MM4 scanning.

The message contents will be scanned for viruses, matched against the file extension blocking lists and scanned for banned words. All these items will be configured via the standard GUI interfaces available for the other protocols and will be controlled at the protection profile level with new options specifically for the MM1 messages.

The FortiOS Carrier unit extracts the sender's Mobile Subscriber Integrated Services Digital Network Number (MSISDN) from the HTTP headers if available. The `POST` payload will be sent to the scanunits which will parse the MMS content and scan each message data section. If any part of the data is to be blocked, the proxy will be informed, the connection to the MMSC will be reset and the Carrier-enabled FortiGate unit will return an `HTTP 200 OK` message with an `m-send-conf` payload to the client to prevent a retry. Finally the appropriate logging, alert, and replacement message events will be triggered.

For client notification, the `x-mms-response-status` and `x-mms-response-text` fields can also be customized as required.

Scanning MM1 retrieval messages

To scan MM1 retrieval messages, expand **MMS Scanning** and select **Scan MM1 message retrieval**.

Select to scan message retrievals that use MM1. If you enable **Virus Scan** for all MMS interfaces, messages are also scanned while being sent. In this case, you can disable MM1 message retrieval scanning to improve performance.

Configuring MMS virus scanning

To configure MMS virus scanning, expand **MMS Scanning** and enable **Virus Scan**.

Once applied to a security policy, the MMS protection profile will then perform virus scans on all traffic accepted by that policy.

Removing or replacing blocked messages

To remove blocked messages, expand **MMS Scanning** and select **Remove Blocked** for the selected MMS types.

Select **Remove Blocked** remove blocked content from each protocol and replace it with the replacement message. If FortiOS Carrier is to preserve the length of the message when removing blocked content, as may occur when billing is affected by the length of the message, select **Constant**.

If you only want to monitor blocked content, select **Monitor Only**.

Carrier Endpoint Block

A carrier endpoint defines a specific client on the carrier network. Typically the client IP address is used to identify the client, however on a carrier network this may be impractical when the client is using a mobile device. Other identifying information such as the MSIDSN number is used instead.

This information can be used to block a specific endpoint on the network. Reasons for blocking may include clients whose accounts have expired, clients from another carrier, clients who have sent malicious content (phishing, exploits, viruses, etc), or other violations of terms of use.

Enabling carrier endpoint blocking

To enable carrier endpoint blocking you first need to create a carrier endpoint filter list, and then enable it.

To enable carrier endpoint blocking - web-based manager

1. Create a carrier endpoint filter list.
2. Go to **Security Profiles > MMS Profile**.
3. Select **Create New**, or select an existing profile to edit and select **Edit**.
4. Expand MMS Scanning.
5. Select one or more types of MMS messaging to enable endpoint blocking on.
6. Select the carrier endpoint filter list to use in matching the endpoints to be blocked.

In MMS Profile, endpoints can only be blocked.

Create a carrier endpoint filter list

A carrier endpoint filter list contains one or more carrier endpoints to match. When used in MMS scanning entries in the filter list that are matched are blocked.

You can configure multiple filter lists for different purposes and groups of clients, such as blocking clients, clients with different levels of service agreements, and clients from other carriers. See Carrier endpoint filter lists configuration settings.

To create a carrier endpoint filter list - web-based manager

1. Go to **Security Profiles > Carrier Endpoint Filter Lists**.
2. Select **Create New**.
3. Enter a descriptive name for the filter list, such as `blocked_clients` or `CountryX_clients`, and select **OK**.
4. Select **Create New** to add one or more entries to the list.
5. Select **OK** to return to display the list of filter lists.

Configuring endpoint filter list entries

For each single endpoint or group of endpoints have part of their identifying information in common, you create an entry in the endpoint filter list.

For example a `blocked_clients` filter list may include entries for single endpoints added as each one needs to be blocked and a group of clients from a country that does not allow certain services.

To configure an endpoint filter list entry - web-based manager

1. Select **Create New**.
2. Enter the following information and select **OK**.

Name	Name of endpoint filter list. Select this name in an MMS protection profile.
Comments	Optional description of the endpoint filter list.

Check/Uncheck All	Select the check box to enable all endpoint patterns in the MMS filter list. Clear the check box to disable all entries on the MMS filter list. You can also select or clear individual check boxes to enable or disable individual endpoint patterns.
Pattern	The pattern that FortiOS Carrier uses to match with endpoints. The pattern can be a single endpoint or consist of wildcards or Perl regular expressions that will match more than one endpoint. For more on wildcard and regular expressions, see Using wildcards and Perl regular expressions in the UTM guide.
Action	Select the action taken by FortiOS Carrier for messages from a carrier endpoint that matches the endpoint pattern: **None** - No action is taken. **Block** - MMS messages from the endpoint are not delivered and FortiOS Carrier records a log message. **Exempt from mass MMS** - MMS messages from the endpoint are delivered and are exempt from mass MMS filtering. Mass MMS filtering is configured in MMS protection profiles and is also called MMS Bulk Email Filtering and includes MMS message flood protection and MMS duplicate message detection. A valid use of mass MMS would be when a service provider notifies customers of a system-wide event such as a shutdown. **Exempt from all scanning** - MMS messages from the endpoint are delivered and are exempt from all MMS protection profile scanning.
Content Archive	MMS messages from the endpoint are delivered, the message content is DLP archived according to MMS DLP archive settings. Content archiving is also called DLP archiving.
Intercept	MMS messages from the endpoint are delivered. Based on the quarantine configuration, attached files may be removed and quarantined.
Pattern Type	The pattern type: **Wildcard**, **Regular Expression**, or **Single Endpoint**.
Enable	Select to enable this endpoint filter pattern.

Blocking network access based on endpoints

You can use endpoint IP filtering to block traffic from source IP addresses associated with endpoints. You can also configure FortiOS Carrier to record log messages whenever endpoint IP filtering blocks traffic. Endpoint IP filtering blocks traffic at the IP level, before the traffic is accepted by a security policy.

To configure endpoint IP filtering, go to **Security Profiles > Carrier > IP Filter** and add endpoints to the IP filter list. For each endpoint you can enable or disable both blocking traffic and logging blocked traffic.

You cannot add endpoint patterns to the endpoint IP filter list. You must enter complete and specific endpoints that are valid for your network.

The only action available is block. You cannot use endpoint IP filtering to exempt endpoints from IP filtering or to content archive or quarantine communication sessions.

FortiOS Carrier looks in the current user context list for the endpoints in the IP filter list and extracts the source IP addresses for these endpoints. Then any communication session with a source IP address that matches one of these IP addresses is blocked at the IP level, before the communication session is accepted by a security policy.

FortiOS Carrier dynamically updates the list of IP addresses to block as the user context list changes. Only these updated IP addresses are blocked by endpoint IP filtering.

For information about the carrier endpoints and the user context list, including how entries are added to and removed from this list.

MMS Content Checksum

The MMS content checksum feature attempts to match checksums of known malicious MMS messages, and on a successful match it will be blocked. The checksums are applied to each part of the message—attached files and message body have separate checksums. These checksums are created with CRC-32, the same method as FortiAnalyzer checksums.

For example, if an MMS message contains a browser exploit in the message body, you can add the checksum for that message body to the list, and future occurrences of that exact message will be blocked. Content will be replaced by the content checksum block notification replacement message for that type of MMS message, and if it is enabled the event will be logged.

One possible implementation would to configure all .sis files to be intercepted. When one is found to be infected or malicious it would be added to the MMS content checksum list.

To use this feature a list of one or more malicious checksums must be created and then the feature is enabled using that list. For a detailed list of options, see MMS Content Checksum.

To configure an MMS content checksum list

1. Go to **Security Profiles > MMS Content Checksum**.
2. Select **Create New**.
3. Enter a name for the list of checksums, and select **OK**.
   You are taken to the edit screen for that new list.
4. Select ***Create New*** to add a checksum.
5. Enter the ***Name*** and ***Checksum***, and select **OK**.
   The checksum is added to the list.

To add more checksums to the list, repeat steps 4 and 5.

To to remove a checksum from the list you can either delete the checksum or simply disable it and leave it in the list.

To enable MMS content checksums, expand **MMS Scanning** and select **MMS Content Checksum** for the selected MMS types. Select the checksum list to match.

Passing or blocking fragmented messages

Select to pass fragmented MM3 and MM4 messages. Fragmented MMS messages cannot be scanned for viruses. If you do not select these options, fragmented MM3 and MM4 message are blocked.

The Interval is the time in seconds before client comforting starts after the download has begun, and the time between sending subsequent data.

The **Amount** is the number of bytes sent by client or server comforting at each interval.

Client comforting

In general, client comforting is available for for MM1 and MM7 messaging and provides a visual display of progress for web page loading or HTTP or FTP file downloads. Client comforting does this by sending the first few packets of the file or web page being downloaded to the client at configured time intervals so that the client is not aware that the download has been delayed. The client is the web browser or FTP client. Without client comforting, clients and their users have no indication that the download has started until the Carrier-enabled FortiGate unit has completely buffered and scanned the download. During this delay users may cancel or repeatedly retry the transfer, thinking it has failed.

The appearance of a client comforting message (for example, a progress bar) is client-dependent. In some instances, there will be no visual client comforting cue.

During client comforting, if the file being downloaded is found to be infected, then the Carrier-enabled FortiGate unit caches the URL and drops the connection. The client does not receive any notification of what happened because the download to the client had already started. Instead the download stops, and the user is left with a partially downloaded file.

If the user tries to download the same file again within a short period of time, then the cached URL is matched and the download is blocked. The client receives the Infection cache message replacement message as a notification that the download has been blocked. The number of URLs in the cache is limited by the size of the cache.

Client comforting can send unscanned (and therefore potentially infected) content to the client. Only enable client comforting if you are prepared to accept this risk. Keeping the client comforting interval high and the amount low will reduce the amount of potentially infected data that is downloaded.

MM1 and MM7 client comforting steps

Since MM1 and MM7 messages use HTTP, MM1 and MM7 client comforting operates like HTTP client comforting.

The following steps show how client comforting works for a download of a 1 Mbyte file with the client comforting interval set to 20 seconds and the client comforting amount set to 512 bytes.

1. The client requests the file.
2. The Carrier-enabled FortiGate unit buffers the file from the server. The connection is slow, so after 20 seconds about one half of the file has been buffered.

3. The Carrier-enabled FortiGate unit continues buffering the file from the server, and also sends 512 bytes to the client.
4. After 20 more seconds, the FortiGate unit sends the next 512 bytes of the buffered file to the client.
5. When the file has been completely buffered, the client has received the following amount of data:

   `ca * (T/ci) bytes == 512 * (40/20) == 512 * 2 == 1024 bytes,`

   where `ca` is the client comforting amount, `T` is the buffering time and `ci` is the client comforting interval.
6. If the file does not contain a virus, the Carrier-enabled FortiGate unit sends the rest of the file to the client. If the file is infected, the FortiGate closes the data connection but cannot send a message to the client.

Server comforting

Server comforting can be selected for each protocol.

Similar to client comforting, you can use server comforting to prevent server connection timeouts that can occur while waiting for FortiOS Carrier to buffer and scan large `POST` requests from slow clients.

The **Interval** is the time in seconds before client and server comforting starts after the download has begun, and the time between sending subsequent data.

The **Amount** is the number of bytes sent by client or server comforting at each interval.

Handling oversized MMS messages

Select **Block** or **Pass** for files and email messages exceeding configured thresholds for each protocol.

The oversize threshold refers to the final size of the message, including attachments, after encoding by the client. Clients can use a variety of encoding types; some result in larger file sizes than the original attachment. As a result, a file may be blocked or logged as oversized even if the attachment is several megabytes smaller than the oversize threshold.

Sender notifications and logging

In most cases you will notify the sender that they are causing problems on the network — either by sending malware content, flooding the network, or some other unwanted activity. The notification assumes the sender is unaware of their activity and will stop or correct it when notified.

However, senders who are notified may use this information to circumvent administration's precautions. For example if flood notification is set to 1000 messages per minute, a notified user may simply reduce their message to 990 messages per minute if this flood is intentional. For this reason, not all problems include sender notifications.

There are two methods of notifying senders:

- MMS notifications
- Replacement messages

And three details to consider for logging and notifying administrators:

- Logging and reporting
- MMS logging options
- SNMP

MMS notifications

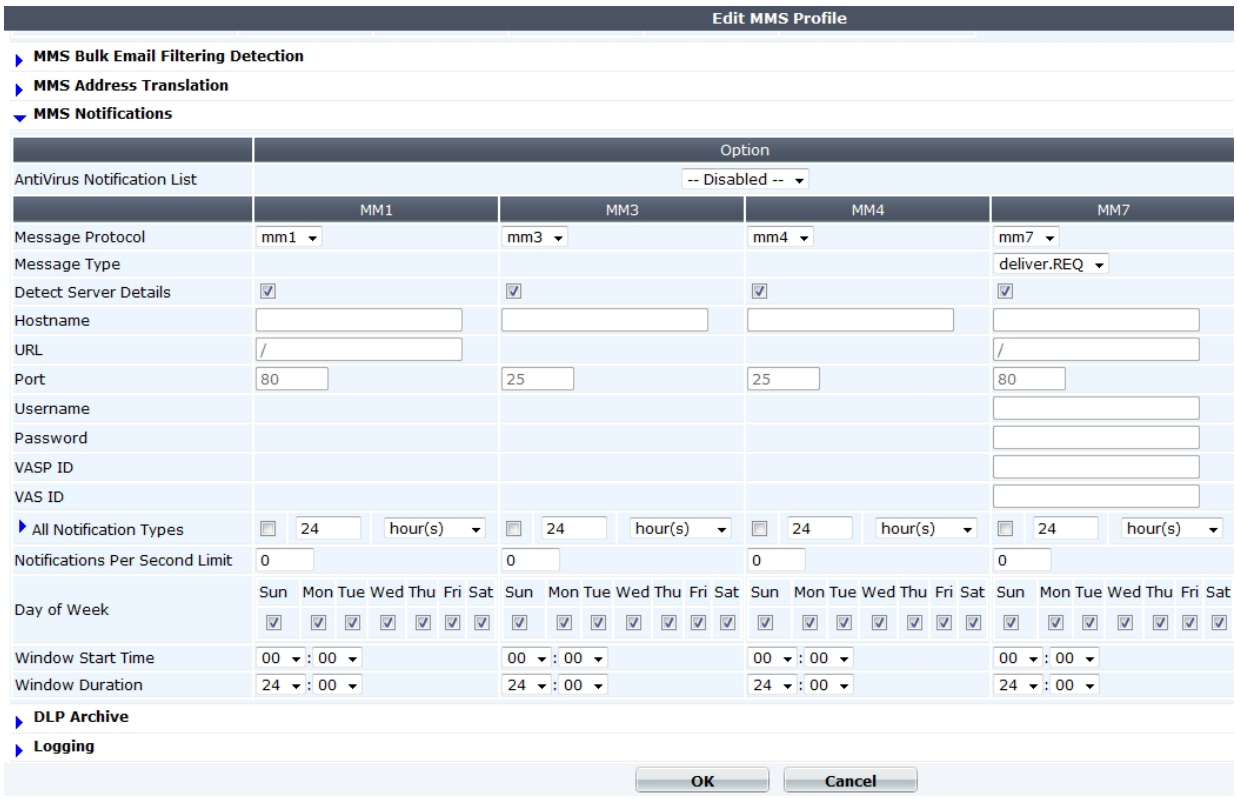
MMS notifications enable you to customize notifications for many different situations and differently for all the supported MMS message protocols — MM1, MM3, MM4, and MM7.

MMS notification types include:

- Content Filter
- File Block
- Carrier Endpoint Block
- Flood
- Duplicate
- MMS Content Checksum
- Virus Scan

Day of Week, **Window start time** and **Window Duration** define what days and what time of day alert notifications will be sent. This allows you to control what alerts are sent on weekends. It also lets you control when to start sending notifications each day. This can be useful if system maintenance is performed at the same time each night — you might want to start alert notifications after maintenance has completed. Another reason to limit the time alert messages are sent could be to limit message traffic to business hours.

Notifications screen for FortiOS Carrier MMS Profile



For MMS Notification options, see MMS Notifications.

Replacement messages

FortiGate units send replacement messages when messages or content is blocked, quarantined, or otherwise diverted from the receiver. In it's place a message is sent to notify the receiver what happened.

With FortiOS Carrier MMS replacement messages, send and receive message types are supported separately and receive their own custom replacement messages. This allows the network to potentially notify both the sender and reciever of the problem.

For example the replacement message **MM1 send-req file block message** is sent to the device that sent one or more files that were banned. The default message that is sent is `This device has sent %%NUM_MSG%% messages containing banned files in the last %%DURATION%% hours.` The two variables are replaced by the appropriate values.

Replacement messages are not as detailed or specific as MMS notifications, but they are also not as complicated to configure. They are also useful when content has been removed from an MMS message that was still delivered.

Logging and reporting

With each virus infection, or file block, a syslog message is generated. The format of this syslog message is similar to:

```
2005-09-22 19:15:47 deviceid=FGT5001ABCDEF1234 logid=0211060ABC type=virus
    subtype=infected level=warning src=10.1.2.3 dst=10.2.3.4 srcintf=port1 dstintf=port2
    service=mm1 status=blocked from="<sending MSISDN>" to="<receiving MSISDN>"
    file="eicar.com.txt" virus="EICAR_TEST_FILE" msg="The file eicar.com.txt is infected
    with EICAR_TEST_FILE. ref
    http://www.fortinet.com/VirusEncyclopedia/search/encyclopediaSearch.do?method=quickSea
    rchDirectly&virusName=EICAR_TEST_FILE"
```

Note that the **from** and **to** fields are samples and not real values.

MMS logging options

You can enable logging in an MMS protection profile to write event log messages when the MMS protection profile options that you have enabled perform an action. For example, if you enable MMS antivirus protection, you could also use the MMS protection profile logging options to write an event log message every time a virus is detected.

To record these log messages you must first configure how the FortiOS Carrier unit stores log messages.

To configure MMS content archiving, go to **Security Profiles > MMS Profile**. Select **Create New** or select the **Edit** icon beside an existing profile. Expand **MMS Bulk AntiSpam Detection > Logging**. Complete the fields as described in the following table and select **OK**. For more a detailed list of options, see Logging.

SNMP

A simple SNMP trap will be generated to inform the operators' alerting system that a virus has been detected. This SNMP trap could contain the sending and receiving MSISDN, however the initial solution would reflect the current behavior, i.e. only the fact that a virus has been detected will be communicated.

MMS content-based Antispam protection

Expand **MMS Scanning** and select **Content Filter** in an MMS protection profile to create content filter black/white lists that block or allow MMS messages based on the content of the message.

Overview

A school computer lab may block age-inappropriate content. A place of business may block unproductive content. A public access internet cafe may block offensive and graphic content. Each installation has its own requirements for what content needs to be blocked, and in what language.

FortiOS Carrier provides the ability to create custom local dictionaries, black lists, and white lists in multiple languages enables you to protect your customers from malicious content around the world.

Configurable dictionary

You can create a dictionary of configurable terms and phrases using the CLI. The text of MMS messages will be searched for these terms and phrases. Add content filter lists that contain content that you want to match in MMS messages. For every match found, a score is added. If enough matches are found to set the total score above the configured threshold, the MMS message is blocked.

You can add words, phrases, wild cards and Perl regular expressions to create content patterns that match content in MMS messages. For more on wildcard and regular expressions, see Using wildcards and Perl regular expressions in the UTM guide.

For each pattern you can select **Block** or **Exempt**.

- Block adds an antispam black list pattern. A match with a block pattern blocks a message depending on the score of the pattern and the content filter threshold.
- Exempt adds an antispam white list pattern. A match with an exempt pattern allows the message to proceed through the FortiOS Carrier unit, even if other content patterns in the same content filter list would block it.

If a pattern contains a single word, the FortiOS Carrier unit searches for the word in MMS messages. If the pattern contains a phrase, the FortiOS Carrier unit searches for all of the words in the phrase. If the pattern contains a phrase in quotation marks, the FortiOS Carrier unit searches for the whole phrase.

You can create patterns with Simplified Chinese, Traditional Chinese, Cyrillic, French, Japanese, Korean, Spanish, Thai, or Western character sets.

Black listing

Black listing is the practice of banning entries on the list. For example if an IP address continuously sends viruses, it may be added to the black list. That means any computers that consult that list will not communicate with that IP address.

Sometimes computers or devices can be added to black lists for a temporary problem, such as a virus that is removed when notified. However, as a rule short of contacting the administrator in person to manually be removed form the black list, users have to wait and they generally will be removed after a period without problem.

White listing

White listing is the practice of adding all critical IP addresses to a list, such as company email and web servers. Then if those servers become infected and start sending spam or viruses, those servers are not blocked. This allows the critical traffic through, even if there might be some malicious traffic as well. Blocking all traffic from your company servers would halt company productivity.

Scores and thresholds

Each content pattern incudes a score. When a MMS message is matched with a pattern the score is recorded. If a message matches more than one pattern or matches the same pattern more than once, the score for the message increases. When the total score for a message equals or exceeds the threshold the message is blocked.

The default score for a content filter list entry is 10 and the default threshold is 10. This means that by default a message is blocked by a single match. You can change the scores and threshold so that messages can only be blocked if there are multiple matches. For example, you may only want to block messages that contain the phrase “example” if it appears twice. To do this, add the “example” pattern, set action to block and score to 5. Keep the threshold at 10. If “example” is found twice or more in a message the score adds up 10 (or more) and the message is blocked.

Configuring content-based antispam protection

To apply content-based antispam protection - CLI

```
config webfilter content
   edit <filter_table_number>
      set name <filter_table_name>
      config entries
         edit <phrase or regexp you want to block>
            set action {block | exempt}
            set lang <phrase language>
            set pattern-type {wildcard | regexp}
            set score <phrase score>
```

```
        set status {enable | disable}
    end
end
```

Configuring sender notifications

When someone on the MMS network sends an MMS message that is blocked, in most cases you will notify the sender. Typically an administrator is notified in addition to the sender so action can be taken if required. There are two types of sender notifications available in FortiOS Carrier: MMS notifications, and Replacement Messages.

MMS notifications

MMS notifications to senders are configured in **Security Profiles > MMS Profile**, under MMS Notifications.

In this section you can configure up to four different notification recipients for any combination of MM1/3/4/7 protocol MMS messages. Also for MM7 messages the message type can be `submit.REQ` or `deliver.REQ`.

Useful settings include:

- delay in message based on notification type
- limit on notifications per second to prevent a flood
- schedules for notifications
- log in details for MM7 messages.

For more information on MMS notifications, see Notifying message flood senders and receivers and MMS Notifications.

Replacement messages

Replacement messages are features common to both FortiOS and FortiOS Carrier, however FortiOS Carrier has additional messages for the MMS traffic.

While each MMS protocol has its own different rec placement messages, the one common to all MMS protocols is the **MMS blocked content replacement message**. This is the message that the receiver of the message sees when their content is blocked.

MMS DLP archiving

You can use DLP archiving to collect and view historical logs that have been archived to a FortiAnalyzer unit or the FortiGuard Analysis and Management service. DLP archiving is available for FortiAnalyzer when you add a FortiAnalyzer unit to the FortiOS Carrier configuration. The FortiGuard Analysis and Management server becomes available when you subscribe to the FortiGuard Analysis and Management Service.

You can configure full DLP archiving and summary DLP archiving. Full DLP archiving includes all content, for example, full email DLP archiving includes complete email messages and attachments. Summary DLP archiving includes just the meta data about the content, for example, email message summary records include only the email header.

You can archive MM1, MM3, MM4, and MM7 content.

Configuring MMS DLP archiving

Select DLP archive options to archive MM1, MM3, MM4, and MM7 sessions. For each protocol you can archive just session metadata (**Summary**), or metadata and a copy of the associated file or message (**Full**).

In addition to MMS protection profile DLP archive options you can:

- Archive MM1 and MM7 message floods
- Archive MM1 and MM7 duplicate messages
- Select **DLP archiving** for carrier endpoint patterns in a **Carrier Endpoint List** and select the **Carrier Endpoint Block** option in the **MMS Scanning** section of an MMS Protection Profile

FortiOS Carrier only allows one sixteenth of its memory for transferring content archive files. For example, for Carrier-enabled FortiGate units with 128MB RAM, only 8MB of memory is used when transferring content archive files. Best practices dictate to not enable full content archiving if antivirus scanning is also configured because of these memory constraints.

To configure MMS DLP archiving - web-based manager

1. Go to **Security Profiles > MMS Profile**.
2. Select **Create New** or select the **Edit** icon beside an existing profile.
3. Expand **MMS Bulk AntiSpam Detection > Content Archive**.
4. Complete the fields as described in DLP Archive options.
5. Select **OK**.

Viewing DLP archives

You can view DLP archives from the Carrier-enabled FortiGate unit web-based manager. Archives are historical logs that are stored on a log device that supports archiving, such as a FortiAnalyzer unit.

These logs are accessed from either **Log & Report > DLP Archive** or if you subscribed to the FortiCloud service, you can view log archives from there.

The **DLP Archive** menu is only visible if one of the following is true.

- You have configured the FortiGate unit for remote logging and archiving to a FortiAnalyzer unit.
- You have subscribed to FortiCloud.

The following tabs are available when you are viewing DLP archives for one of these protocols.

- **E-mail** to view POP3, IMAP, SMTP, POP3S, IMAPS, SMTPS, and spam email archives.
- **Web** to view HTTP and HTTPS archives.
- **FTP** to view FTP archives.
- **IM** to view AIM, ICQ, MSN, and Yahoo! archives.
- **MMS** to view MMS archives.
- **VoIP** to view session control (SIP, SIMPLE and SCCP) archives.

If you need to view log archives in Raw format, select **Raw** beside the **Column Settings** icon.

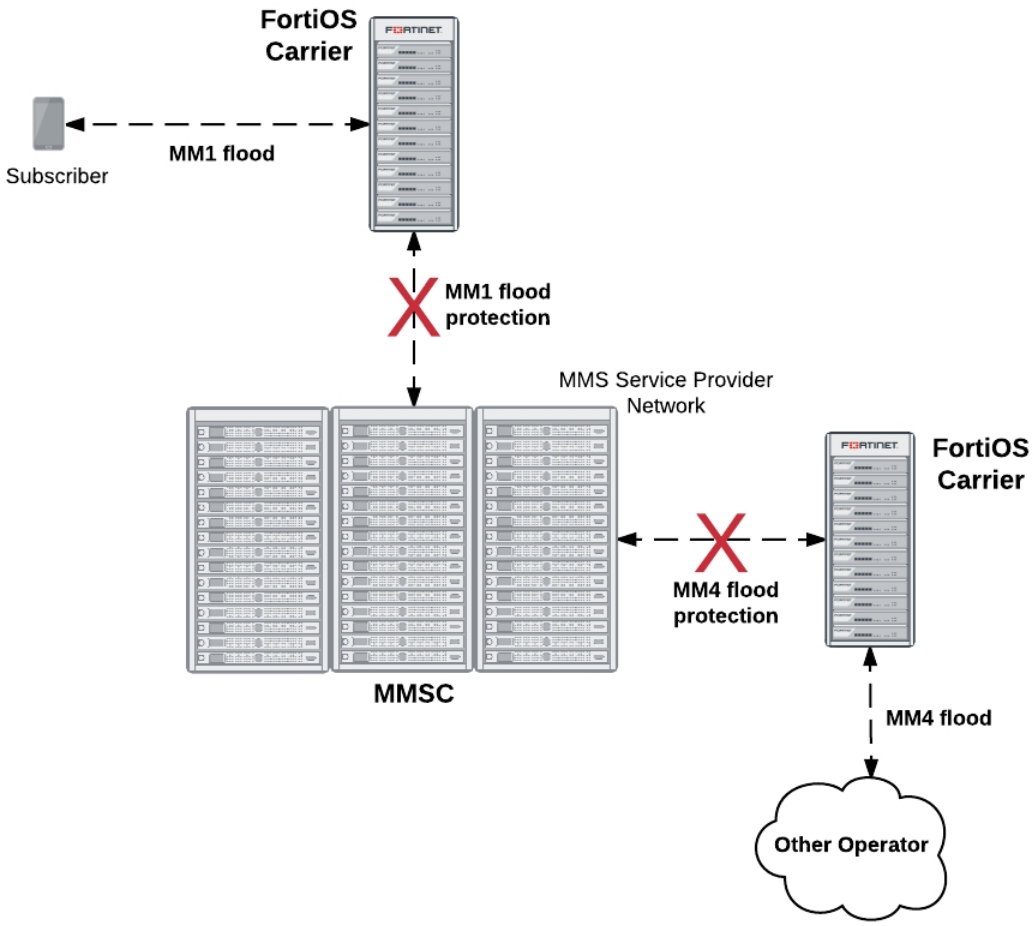
Message flood protection

The convenience offered by MM1 and MM4 messaging can be abused by users sending spam or attempting to overload the network with an excess of messages. MMS flood prevention can help prevent this type of abuse.

Overview

Flood protection for MM1 messages prevents your subscribers from sending too many messages to your MMSC. Configuring flood protection for MM4 messages prevents another service provider from sending too many messages from the same subscriber to your MMSC.

MM1 and MM4 flood protection



The FortiOS Carrier unit keeps track of the number of messages each subscriber sends for the length of time you specify. If the number of messages a subscriber sends exceeds the threshold, a configured action is taken.

Possible actions are logging the flood, blocking or intercepting messages in the flood, archiving the flood messages, and sending an alert message to inform the administrator that the flood is occurring.

You can create three different thresholds to take different levels of action at different levels of activity.

With this highly configurable system, you can prevent subscribers from sending more messages than you determine is acceptable, or monitor anyone who exceeds the thresholds.

Setting message flood thresholds

A message flood occurs when a single subscriber sends a volume of messages that exceeds the flood threshold you set. The threshold defines the maximum number of messages allowed, the period during which the subscriber sent messages are considered, and the length of time the sender is restricted from sending messages after a flood is detected.

If a subscriber exceeds the message flood threshold and is blocked from sending more messages, any further attempts to send messages will re-start the block period. You must also enable logging for **MMS Scanning > Bulk Messages** in the Logging section of the MMS protection profile.

A subscriber is still able to receive messages while they are blocked from sending messages.

Example

For example, for the first threshold you may determine that any subscriber who sends more than 100 MM1 messages in an hour (60 minutes) will have all messages blocked for half an hour (30 minutes).

Using this example, if the subscriber exceeds the flood threshold, they are blocked from sending message for 30 minutes. If the subscriber tries to send any message after 15 minutes, the message will be blocked and the block period will be reset again to 30 minutes. The block period must expire with no attempts to send a message. Only then will the subscriber be allowed to send more messages.

To configure MM1 message flood threshold - web-based manager

1. Go to **Security Profiles > MMS Profile**.
2. Select **Create New**.
3. Enter `MM1 flood` for **Profile Name**.
4. Expand **MMS Bulk Email Filtering Detection**.
5. Enter the following information, and select **OK**.

MM1 (first column)	
Enable	Enable
Message Flood Window	60 minutes
Message Flood Limit	100
Message Flood Block Time	30 minutes
Message Flood Action	Block

To configure MM1 message flood threshold - CLI

```
config firewall mms-profile
   edit profile_name
      config flood mm1
         set status1 enable
         set window1 60
         set limit1 100
         set action1 block
         set block-time1 30
      end
   end
```

The threshold values that you set for your network will depend on factors such as how busy your network is and the kinds of problems that your network and your subscribers encounter. For example, if your network is not too busy you may want to set message flood thresholds relatively high so that only an exceptional situation will exceed a flood threshold. Then you can use log messages and archived MMS messages to determine what caused the flood.

If your subscribers are experiencing problems with viruses that send excessive amounts of messages, you may want to set thresholds lower and enable blocking to catch problems as quickly as possible and block access to keep the problem from spreading.

Flood actions

When the Carrier-enabled FortiGate unit detects a message flood, it can take any combination of the five actions that you can configure for the flood threshold. For detailed options, see Message Flood.

Notifying administrators of floods

You can configure alert notifications for message floods by selecting the Alert Notification message flood action.

The FortiOS Carrier unit sends alert notifications to administrators using the MM1, MM3, MM4, or MM7 content interface. To send an alert notification you must configure addresses and other settings required for the content interface.

For example, to send notifications using the MM1 content interface you must configure a source MSISDN, hostname, URL, and port to which to send the notification. You can also configure schedules for when to send the notifications.

Finally you can add multiple MSISDN numbers to the MMS protection profile and set which flood thresholds to send to each MSISDN.

Example — three flood threshold levels with different actions for each threshold

You can set up to three threshold levels to take different actions at different levels of activity.

The first example threshold records log messages when a subscriber's handset displays erratic behavior by sending multiple messages using MM1 at a relatively low threshold. The erratic behavior could indicate a problem with the subscriber's handset. For example, you may have determined for your network that if a subscriber sends more the 45 messages in 30 minutes that you want to record log messages as a possible indication or erratic behavior.

From the web-based manager in an MMS profile set message **Flood Threshold 1** to:

Enable	Selected
Message Flood Window	30 minutes
Message Flood Limit	45
Message Flood Action	Log

From the CLI:

```
config firewall mms-profile
   edit profile_name
      config flood mm1
         set status1 enable
         set window1 30
         set limit1 45
         set action1 log
      end
   end
```

Set a second higher threshold to take additional actions when a subscriber sends more that 100 messages in 30 minutes. Set the actions for this threshold to log the flood, archive the message that triggered the second threshold, and block the sender for 15 minutes.

From the web-based manager in an MMS profile set message **Flood Threshold 2** to:

Enable	Selected
Message Flood Window	30 minutes
Message Flood Limit	100
Message Block Time	15 minutes
Message Flood Action	Log, DLP archive First message only, Block

From the CLI:

```
config firewall mms-profile
   edit profile_name
      config flood mm1
         set status2 enable
         set window2 30
         set limit2 100
         set action2 block log archive-first
         set block-time2 15
      end
   end
```

Set the third and highest threshold to block the subscriber for an extended period and sand an administrator alert if the subscriber sends more than 200 messages in 30 minutes. Set the actions for this threshold to block the sender for four hours (240 minutes), log the flood, archive the message that triggered the third threshold, and send an alert to the administrator.

From the web-based manager in an MMS profile set message **Flood Threshold 3** to:

Enable	Selected
Message Flood Window	30 minutes
Message Flood Limit	200
Message Block Time	240 minutes
Message Flood Action	Log, Block, Alert Notification

Because you have selected the **Alert Notification** action you must also configure alert notification settings. For this example, the source MSISDN is 5551234—telephone number 555-1234. When administrators receive MMS messages from this MSIDSN they can assume a message flood has been detected.

In this example, alert notifications are sent by the FortiOS Carrier unit to the MMSC using MM1. The host name of the MMSC is `mmscexample`, the MMSC URL is `/`, and the port used by the MMSC is 80. In this example, the alert notification window starts at 8:00am and extends for eight hours on weekdays (Monday-Friday) and the minimum interval between message flood notifications is two hours.

Source MSISDN	5551234
Message Protocol	MM1
Hostname	mmscexample
URL	/
Port	80
Notifications Per Second Limit	0
Window Start Time	8:00
Window Duration	8:00
Day of Week	Mon, Tue, Wed, Thu, Fri, Sat
Interval	2 hours

From the CLI:

```
config firewall mms-profile
   edit profile_name
      config notification alert-flood-1
         set alert-src-msisdn 5551234
         set set msg-protocol mm1
         set mmsc-hostname mmscexample
         set mmsc-url /
         set mmsc-port 80
```

```
        set rate-limit 0
        set tod-window-start 8:00
        set tod-window-duration 8:00
        set days-allowed monday tuesday wednesday thursday friday
        set alert-int 2
        set alert-int-mode hours
    end
```

You must also add the MSISDNs of the administrators to be notified of the message flood. In this example, the administrator flood threshold 3 alert notifications are sent to one administrator with MSISDN 5554321.

To add administrator's MSISDNs for flood threshold 3 from the web-based manager when configuring a protection profile, select **MMS Bulk Email Filtering Detection > Recipient MSISDN > Create New**.

MSISDN	5554321
Flood Level 3	Select

From the CLI:

```
config firewall mms-profile
   edit profile_name
      config notif-msisdn
         edit 5554321
            set threshold flood-thresh-3
      end
end
```

Notifying message flood senders and receivers

The FortiOS Carrier unit does not send notifications to the sender or receiver that cause a message flood. If the sender or receiver is an attacker and is explicitly informed that they have exceeded a message threshold, the attacker may try to determine the exact threshold value by trial and error and then find a way around flood protection. For this reason, no notification is set to the sender or receiver.

However, FortiOS Carrier does have replacement messages for sending reply confirmations to MM1 senders and receivers and for MM4 senders for blocked messages identified as message floods. For information about how FortiOS Carrier responds when message flood detection blocks a message, see and MMS duplicate messages and message floods.

Responses to MM1 senders and receivers

When the FortiOS Carrier unit identifies an MM1 message sent by a sender to an MMSC as a flood message and blocks it, the FortiOS Carrier unit returns a message submission confirmation (`m-send.conf`) to the sender — otherwise the sender's handset would keep retrying the message. The `m-send.conf` message is sent only when the MM1 message flood action is set to Block. For other message flood actions the message is actually delivered to the MMSC and the MMSC sends the `m-send.conf` message.

You can customize the `m-send.conf` message by editing the **MM1 send-conf flood message** MM1 replacement message (from the CLI the `mm1-send-conf-flood` replacement message). You can customize the response status and message text for this message. The default response status is "Content not accepted". To hide the fact that FortiOS Carrier is responding to a flood, you can change the response status to "Success".

The default message text informs the sender that the message was blocked. You could change this to something more generic.

For example, the following command sets the submission confirmation response status to “Success” and changes the message text to “Message Sent OK”:

```
config system replacemsg mm1 mm1-send-conf-flood
   set rsp-status ok
   set rsp-text “Message Sent OK”
end
```

When the FortiOS Carrier unit identifies an MM1 message received by a receiver from an MMSC as a flood message and blocks it, the FortiOS Carrier unit returns a message retrieval confirmation (m-retrieve.conf) to the sender (otherwise the sender’s handset would keep retrying the message). The m-retrieve.conf message is sent only when the MM1 message flood action is set to Block. For other message flood actions the message is actually delivered to the receiver, so the MMSC sends the m-retrieve.conf message.

You can customize the m-retrive.conf message by editing the **MM1 retrieve-conf flood message** MM1 replacement message (from the CLI the `mm1-retr-conf-flood` replacement message). You can customize the class, subject, and message text for this message.

For example, you could use the following command make the response more generic:

```
config system replacemsg mm1 mm1-retr-conf-flood
   set subject “Message blocked”
   set message “Message temporarily blocked by carrier”
end
```

Forward responses for MM4 message floods

When the FortiOS Carrier unit identifies an MM4 message as a flood message and blocks it, the FortiOS Carrier unit returns a message forward response (MM4_forward.res) to the forwarding MMSC (otherwise the forwarding MMSC would keep retrying the message). The MM4_forward.res message is sent only when the MM4 message flood action is set to Block and the MM4-forward.req message requested a response. For more information, see and MMS duplicate messages and message floods.

You can customize the MM4_forward.res message by editing the **MM4 flood message** MM4 replacement message (from the CLI the `mm4-flood` replacement message). You can customize the response status and message text for this message. The default response status is “Content not accepted” (`err-content-not-accept`). To hide the fact that the FortiOS Carrier unit is responding to a flood, you can change the response status to “Success”. The default message text informs the sender that the message was blocked. You could change this to something more generic.

For example, the following command sets the submission confirmation response status to “Success” and changes the message text to “Message Sent OK” for the MM4 message forward response

```
config system replacemsg mm4 mm4-flood
   set rsp-status ok
   set rsp-text “Message Forwarded OK”
end
```

Viewing DLP archived messages

If **DLP Archive** is a selected message flood action, the messages that exceed the threshold are saved to the MMS DLP archive. The default behavior is to save all of the offending messages, but you can configure the DLP

archive setting to save only the first message that exceeds the threshold. This still provides a sample of the offending messages without requiring as requiring as much storage.

To select only the first message in a flood for DLP archiving - web-based manager

1. Go to **Security Profiles > Carrier > MMS Profile**.
2. Edit an existing MMS Profile.
3. Expand the **MMS Bulk Email Filtering Detection** section, the **Message Flood** subsection, and the desired **Flood Threshold** subsection.
4. Next to **DLP Archive**, select **First message only** from the dropdown menu.
5. Select **OK**.

Order of operations: flood checking before duplicate checking

Although duplicate checking involves only examination and comparison of message contents and not the sender or recipient, and flood checking involves only totalling the number of messages sent by each subscriber regardless of the message content, there are times when a selection of messages exceed both flood and duplicate thresholds.

The Carrier-enabled FortiGate unit checks for message floods before checking for duplicate messages. Flood checking is less resource-intensive and if the flood threshold invokes a **Block** action, the blocked messages are stopped before duplicate checking occurs. This saves both time and FortiOS Carrier system resources.

The duplicate scanner will only scan content. It will not scan headers. Content must be exactly the same. If there is any difference at all in the content, it will not be considered a duplicate.

Bypassing message flood protection based on user's carrier endpoints

You can use carrier endpoint filtering to exempt MMS sessions from message flood protection. Carrier endpoint filtering matches carrier endpoints in MMS sessions with carrier endpoint patterns.

If you add a carrier endpoint pattern to a filter list and set the action to exempt from mass MMS, all messages from matching carrier endpoints bypass message flood protection. This allows legitimate bulk messages, such as system outage notifications, to be delivered without triggering message flood protection.

For more information on carrier endpoints, see the User Authentication chapter of the FortiOS Handbook.

Configuring message flood detection

To have the Carrier-enabled FortiGate unit check for message floods, you must first configure the flood threshold in an MMS profile, select the MMS profile in a security policy. All the traffic examined by the security policy will be checked for message floods according to the threshold values you set in the MMS profile.

Configure the MMS profile - web-based manager

1. Go to **Firewall Objects > MMS Profile**.
2. If you are editing an MMS profile, select the **Edit** icon of the MMS profile.
   If you are creating a new MMS profile, select **Create New** and enter a profile name.

3. Expand **MMS Bulk Email Filtering Detection**.
4. Expand **Message Flood**.
5. Expand **Flood Threshold 1**.
6. Select the **Enable** check box for MM1 messages, MM4 messages, or both.
7. In the **Message Flood Window** field, enter the length of time the Carrier-enabled FortiGate unit will keep track of the number of messages each subscriber sends.

   If the Carrier-enabled FortiGate unit detects the quantity of messages specified in the **Message Flood Limit** sent during the number of minutes specified in the **Message Flood Window**, a message flood is in progress.
8. In the **Message Flood Limit** field, enter the number of messages required to trigger the flood.
9. In the **Message Flood Block Time** field, enter the length of time a user will be blocked from sending messages after causing the message flood.
10. Select the message flood actions the Carrier-enabled FortiGate unit will take when the message flood is detected.
11. Select **OK**.

Configure the security policy - web-based manager

1. Go to **Policy**.
2. Select the **Edit** icon of the security policy that controls the traffic in which you want to detect message floods.
3. Select the **MMS Profile** check box to enable the use of a protection profile.
4. Select the MMS protection profile from the list.
5. Select **OK**.

Sending administrator alert notifications

When message floods are detected, the Carrier-enabled FortiGate unit can be configured to notify you immediately with an MMS message. Enable this feature by selecting Alert Notification in the message flood action. Each message flood threshold can be configured separately.

Configuring how and when to send alert notifications

You can configure different alert notifications for MM1 and MM4 message floods. You can configure the FortiOS Carrier unit to send these alert notifications using the MM1, MM3, MM4, or MM7 content interface. Each of these content interfaces requires alert notification settings that the FortiOS Carrier unit uses to communicate with a server using the selected content interface.

For the MM1 content interface you require:

- The hostname of the server
- The URL of the server (usually “/”)
- The server port (usually 80)

For the MM3 and MM4 content interfaces you require:

- The hostname of the server
- The server port (usually 80)
- The server user domain

For the MM7 content interface you require:

- The message type
- ***submit.REQ*** to send a notification message to the sender in the form of a submit request. The message goes from a VAS application to the MMSC.
- ***deliver.REQ*** to send a notification message to the sender in the form of a deliver request. The message goes from the MMSC to a VAS application.
- The hostname of the server
- The URL of the server (usually "/")
- The server port (usually 80)
- A user name and password to connect to the server
- The value-added-service-provider (VASP) ID
- The value-added-service (VAS) ID

For more information, see MMS notifications.

To configure administrator alert notifications - web-based manager

1. Go to **Firewall Objects > MMS Profile** and edit or add a new MMS protection profile.
2. Expand **MMS Bulk Email Filtering Detection**.
   There are three message flood thresholds.
3. Expand the threshold that you want to configure alert notification for.
4. For **Message Flood Action**, select the **Alert Notification** check box. Alert notification options appear.
5. For the **Source MSISDN**, enter the MSISDN from which the alert notification message will be sent.
6. Select the Message Protocol the alert notification will use: **MM1**, **MM3**, **MM4**, or **MM7**.
7. Add the information required by FortiOS Carrier to send messages using the selected message protocol:
8. For **Notifications Per Second Limit**, enter the number of notifications to send per second.
   Use this setting to reduce control the number of notifications sent by the FortiOS Carrier unit. If you enter zero (0), the notification rate is not limited.
9. If required, change **Window Start Time** and **Window Duration** configure when the FortiOS Carrier unit sends alert notifications.
   By default, notifications are sent at any time of the day. You can change the Window Start Time if you want to delay sending alert messages. You can also reduce the Window Duration if you want to stop sending alert notifications earlier.

   For example, you might not want FortiOS Carrier sending notifications except during business hours. In this case the Window Start Time could be 9:00 and the Window Duration could be 8:00 hours.

   You can set different alert notifications for each message threshold. For example, you could limit the message window for lower thresholds and set it to 24 hours for higher thresholds. This way administrators will only receive alert notifications outside of business hours for higher thresholds.
10. For **Day of Week**, select the days of the week to send notifications.
    For example, you may only want to send alert notifications on weekends for higher thresholds.
11. In the **Interval field**, enter the maximum frequency that alert notification messages will be sent, in minutes or hours.
    All alerts occurring during the interval will be included in a single alert notification message to reduce the number of alert messages that are sent.

Configuring who to send alert notifications to

In each MMS protection profile you add a list of recipient MSISDNs. For each of these MSISDNs you select the message flood threshold that triggers sending notifications to this MSISDN.

To configure the alert notification recipients - web-based manager

1. Go to **Firewall Objects > MMS Profile**.
2. Select the **Edit** icon of the MMS profile in which you want to configure the alert notification recipients.
3. Expand **MMS Bulk Email Filtering Detection**.
4. Expand **Recipient MSISDN**.
5. Select **Create New**.
6. In the **New MSISDN** window, enter the MSISDN to use for flood threshold alert notification.
7. Select the duplicate thresholds at which to send alert notifications to the MSISDN.

For the flood threshold to be able to send an alert notification to the MSISDN, the alert notification action must be enabled and configured within the flood threshold.

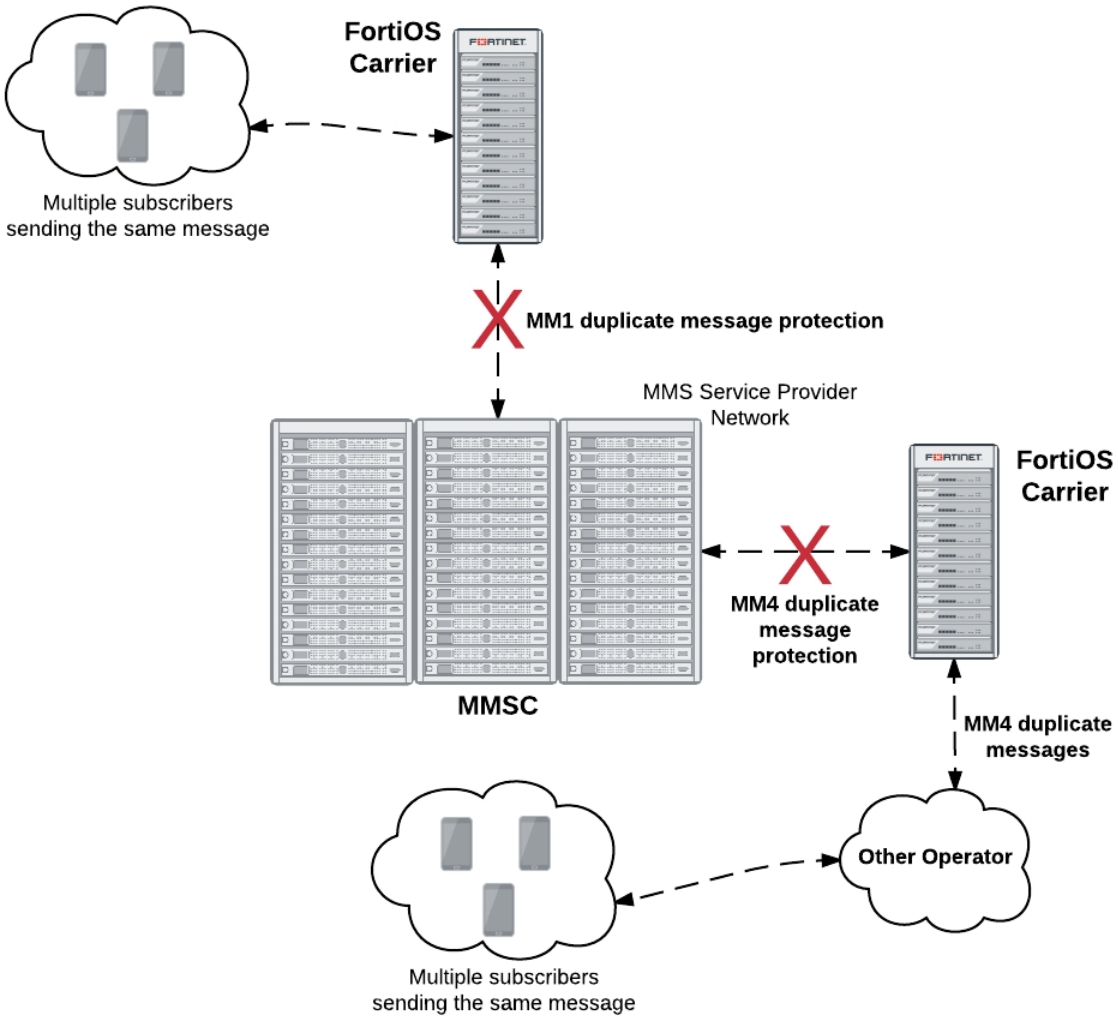
Duplicate message protection

The convenience offered by MM1 and MM4 messaging can be abused by users sending spam or other unwanted messages. Often, the same message will be sent by multiple subscribers. The message can be spam, viral marketing, or worm-generated messages. MMS duplicate prevention can help prevent this type of abuse by keeping track of the messages being sent.

Overview

Duplicate message protection for MM1 messages prevents multiple subscribers from sending duplicate messages to your MMSC. Duplicate message protection for MM4 messages prevents another service provider from sending duplicate messages from the same subscriber to your MMSC. This can help prevent a potential flood that would otherwise become widespread between carriers.

MM1 and MM4 duplicate message protection



The FortiOS Carrier unit keeps track of the sent messages. If the same message appears more often than the threshold value you configure, then action is taken. Possible actions are logging the duplicates, blocking or intercepting duplicate messages, archiving the duplicate messages, and sending an alert to inform an administrator that duplicates are occurring.

With this highly configurable system, you can prevent the transmission of duplicate messages when there are more than you determine is acceptable.

For detailed configuration options, see Duplicate Message.

Using message fingerprints to identify duplicate messages

The Carrier-enabled FortiGate unit detects duplicates by keeping a record of all the messages travelling on the network and comparing new messages to those that have already been sent.

Rather than save the messages, the FortiOS carrier creates a checksum using the message body and subject. This serves as a fingerprint to identify the message. If another message with the same message body and subject appears, the fingerprint will also be the same and the Carrier-enabled FortiGate unit will recognize it as a duplicate.

By creating and saving message fingerprints instead of saving the messages, the Carrier-enabled FortiGate unit can save resources and time.

Messages from any sender to any recipient

Duplicate message detection will detect duplicate messages regardless of the sender or recipient. To do this, message fingerprints are generated using only the message body and subject. The sender, recipient, and other header information is not included.

If multiple messages appear with the same subject and message body, the Carrier-enabled FortiGate unit will recognize them as being the same.

Setting duplicate message thresholds

The FortiOS Carrier recognizes all duplicate messages, but it will take action when it detects a volume of duplicate messages that exceed the duplicate threshold you set. The threshold defines the maximum number of duplicate messages allowed, the period during which the messages are considered, and the length of time the duplicate message can not be sent by anyone.

For example, you may determine that once a duplicate message is sent more than 300 times in an hour, any attempt to send the same duplicate message will be blocked for 30 minutes.

If a particular duplicate message exceeds the duplicate message threshold and is blocked, any further attempts to send the same message will re-start the block period.

Using the example above, if the duplicate message count exceeds the duplicate threshold, any attempt to send a copy of the duplicate message will be blocked for 30 minutes. If a subscriber tries to send a copy of the message after waiting 15 minutes, the message will be blocked and the block period will be reset to 30 minutes. The block period must expire with no attempts to send a duplicate message. Only then will a subscriber be allowed to send the message. Non-duplicate messages will not reset the block period.

Duplicate message actions

When the Carrier-enabled FortiGate unit detects that a duplicate message has exceeded duplicate threshold, it can take any combination of the five actions you configure for the duplicate threshold.

Action	Description
Log	Add a log entry indicating that a duplicate message event has occurred. You must also enable logging for **MMS Scanning > Bulk Messages** in the **Logging** section of the MMS protection profile.
DLP Archive	

Action		Description
	All messages	Save all the messages that exceed the duplicate threshold in the DLP archive.
	First message only	Save the first message to exceed the duplicate threshold in the DLP archive. Subsequent messages that exceed the duplicate threshold will not be saved.
Intercept		Messages that exceed the duplicate threshold are passed to the recipients, but if quarantine is enabled for intercepted messages, a copy of each message is also quarantined for later examination. If the quarantine of intercepted messages is disabled, the **Intercept** action has no effect.
Block		Messages that exceed the duplicate threshold are blocked and will not be delivered to the message recipients. If quarantine is enabled for blocked messages, a copy of each blocked message is quarantined for later examination.
Alert Notification		If the duplicate threshold is exceeded, the Carrier-enabled FortiGate unit will send an MMS duplicate message notification message.

Notifying duplicate message senders and receivers

The FortiOS Carrier unit does not send notifications to the sender or receiver of duplicate messages. If the sender or receiver is an attacker and is explicitly informed that they have exceeded a message threshold, the attacker may try to determine the exact threshold value by trial and error and then find a way around duplicate message protection. For this reason, no notification is set to the sender or receiver.

However, the FortiOS Carrier unit does have replacement messages for sending reply confirmations to MM1 senders and receivers and for MM4 senders for blocked messages identified as duplicate messages. For information about how FortiOS Carrier responds when message flood detection blocks a message, see and MMS duplicate messages and message floods.

Responses to MM1 senders and receivers

When the FortiOS Carrier unit identifies an MM1 message sent by a sender to an MMSC as a duplicate message and blocks it, the FortiOS Carrier unit returns a message submission confirmation (m-send.conf) to the sender (otherwise the sender's handset would keep retrying the message). The m-send.conf message is sent only when the MM1 duplicate message action is set to Block. For other duplicate message actions the message is actually delivered to the MMSC and the MMSC sends the m-send.conf message.

You can customize the m-send.conf message by editing the **MM1 send-conf duplicate message** MM1 replacement message (from the CLI the `mm1-send-conf-dupe` replacement message). You can customize the response status and message text for this message. The default response status is "Content not accepted". To hide the fact that the FortiOS Carrier unit is responding to a duplicate message, you can change the response status to "Success". The default message text informs the sender that the message was blocked. You could change this to something more generic.

For example, the following command sets the submission confirmation response status to “Success” and changes the message text to “Message Sent OK”:

```
config system replacemsg mm1 mm1-send-conf-dupe
   set rsp-status ok
   set rsp-text "Message Sent OK"
end
```

When the FortiOS Carrier unit identifies an MM1 message received by a receiver from an MMSC as a duplicate message and blocks it, the FortiOS Carrier unit returns a message retrieval confirmation (m-retrieve.conf) to the sender (otherwise the sender’s handset would keep retrying). The m-retrieve.conf message is sent only when the `MM1duplicate` message action is set to Block. For other message flood actions the message is actually received by the receiver, so the MMSC sends the m-retrieve.conf message.

You can customize the m-retrive.conf message by editing the **MM1 retrieve-conf duplicate message** MM1 replacement message (from the CLI the `mm1-retr-conf-dupe` replacement message). You can customize the class, subject, and message text for this message.

For example, you could use the following command make the response more generic:

```
config system replacemsg mm1 mm1-retr-conf-dupe
   set subject "Message blocked"
   set message "Message temporarily blocked by carrier"
end
```

Forward responses for duplicate MM4 messages

When the FortiOS Carrier unit identifies an MM4 message as a duplicate message and blocks it, the FortiOS Carrier unit returns a message forward response (MM4_forward.res) to the forwarding MMSC (otherwise the forwarding MMSC would keep retrying the message). The MM4_forward.res message is sent only when the MM4 duplicate message action is set to Block and the MM4-forward.req message requested a response. For more information, see and MMS duplicate messages and message floods.

You can customize the MM4_forward.res message by editing the **MM4 duplicate message** MM4 replacement message (from the CLI the `mm4-dupe` replacement message). You can customize the response status and message text for this message. The default response status is “Content not accepted” (`err-content-not-accept`). To hide the fact that the FortiOS Carrier unit is responding to a duplicate message, you can change the response status to “Success”. The default message text informs the sender that the message was blocked. You could change this to something more generic.

For example, the following command sets the submission confirmation response status to “Success” and changes the message text to “Message Forwarded OK”:

```
config system replacemsg mm4 mm4-dupe
   set rsp-status ok
   set rsp-text "Message Forwarded OK"
end
```

Viewing DLP archived messages

If **DLP Archive** is a selected duplicate message action, the messages that exceed the threshold are saved to the MMS DLP archive. The default behavior is to save all of the offending messages but you can configure the DLP archive setting to save only the first message that exceeds the threshold. See Viewing DLP archived messages.

Order of operations: flood checking before duplicate checking

Although duplicate checking involves only examination and comparison of message contents and not the sender or recipient, and flood checking involves only totalling the number of messages sent by each subscriber regardless of the message content, there are times when a selection of messages exceed both flood and duplicate thresholds.

The Carrier-enabled FortiGate unit checks for message floods before checking for duplicate messages. Flood checking is less resource-intensive and if the flood threshold invokes a **Block** action, the blocked messages are stopped before duplicate checking occurs. This saves both time and FortiOS Carrier system resources.

Bypassing duplicate message detection based on user's carrier endpoints

You can use carrier endpoint filtering to exempt MMS sessions from duplicate message detection. Carrier endpoint filtering matches carrier endpoints in MMS sessions with carrier endpoint patterns. If you add a carrier endpoint pattern to a filter list and set the action to exempt from mass MMS, all messages from matching carrier endpoints bypass duplicate message detection. For more information about endpoints, see FortiOS Handbook User Authentication guide.

Configuring duplicate message detection

To have the Carrier-enabled FortiGate unit check for duplicate messages, configure the duplicate threshold in an MMS profile, and select the MMS profile in a security policy.

All traffic matching the security policy will be checked for duplicate messages according to the settings in the MMS profile.

The duplicate scanner will only scan content. It will not scan headers. Content must be exactly the same. If there is any difference at all in the content, it will not be considered a duplicate.

The modular nature of the profiles allows you great flexibility in how you configure the scanning options. MMS profiles can be used in any number of policies, with different GTP profiles.

In a complex configuration, there may be many security policies, each with a different MMS profile. For a simpler network, you may have many security policies all using the same MMS profile.

Sending administrator alert notifications

When duplicate messages are detected, the Carrier-enabled FortiGate unit can be configured to notify you immediately with an MMS message. Enable this feature by selecting Alert Notification in the duplicate message action. Each duplicate message threshold can be configured separately.

Configuring how and when to send alert notifications

You can configure different alert notifications for MM1 and MM4 duplicate messages. You can configure the FortiOS Carrier unit to send these alert notifications using the MM1, MM3, MM4, or MM7 content interface. Each of these content interfaces requires alert notification settings that the FortiOS Carrier unit uses to communicate with a server using the selected content interface.

For the MM1 content interface you require:

- The hostname of the server
- The URL of the server (usually “/”)
- The server port (usually 80)

For the MM3 and MM4 content interfaces you require:

- The hostname of the server
- The server port (usually 80)
- The server user domain

For the MM7 content interface you require:

- The message type
- **submit.REQ** to send a notification message to the sender in the form of a submit request. The message goes from a VAS application to the MMSC.
- **deliver.REQ** to send a notification message to the sender in the form of a deliver request. The message goes from the MMSC to a VAS application.
- The hostname of the server
- The URL of the server (usually “/”)
- The server port (usually 80)
- A user name and password to connect to the server
- The value-added-service-provider (VASP) ID
- The value-added-service (VAS) ID

To configure administrator alert notifications - web-based manager

1. Go to **Security Profiles > MMS Profile** and edit or add a new MMS protection profile.
2. Expand **MMS Bulk Email Filtering Detection**.
   There are three duplicate message thresholds.
3. Expand the threshold that you want to configure alert notification for.
4. For **Duplicate Message Action**, select the **Alert Notification** check box. Alert notification options appear.
5. For the **Source MSISDN**, enter the MSISDN from which the alert notification message will be sent.
6. Select the Message Protocol the alert notification will use: **MM1**, **MM3**, **MM4**, or **MM7**.
7. Add the information required by FortiOS Carrier to send messages using the selected message protocol:
8. For **Notifications Per Second Limit**, enter the number of notifications to send per second.
   Use this setting to reduce control the number of notifications sent by the FortiOS Carrier unit. If you enter zero (0), the notification rate is not limited.
9. If required, change **Window Start Time** and **Window Duration** configure when the FortiOS Carrier unit sends alert notifications.
   By default, notifications are sent at any time of the day. You can change the Window Start Time if you want to delay sending alert messages. You can also reduce the Window Duration if you want to stop sending alert notifications earlier.

   For example, you might not want FortiOS Carrier sending notifications except during business hours. In this case the Window Start Time could be 9:00 and the Window Duration could be 8:00 hours.

You can set different alert notifications for each message threshold. For example, you could limit the message window for lower thresholds and set it to 24 hours for higher thresholds. This way administrators will only receive alert notifications outside of business hours for higher thresholds.

10. For **Day of Week**, select the days of the week to send notifications.
    For example, you may only want to send alert notifications on weekends for higher thresholds.
11. In the **Interval field**, enter the maximum frequency that alert notification messages will be sent, in minutes or hours.
    All alerts occurring during the interval will be included in a single alert notification message to reduce the number of alert messages that are sent.

Configuring who to send alert notifications to

In each MMS protection profile you add a list of recipient MSISDNs. For each of these MSISDNs you select the duplicate threshold that triggers sending notifications to this MSISDN.

To configure the alert notification recipients - web-based manager

1. Go to **Security Profiles > MMS Profile**.
2. Select the **Edit** icon of the MMS profile in which you want to configure the alert notification recipients.
3. Expand **MMS Bulk Email Filtering Detection**.
4. Expand **Recipient MSISDN**.
5. Select **Create New**.
6. In the **New MSISDN** window, enter the MSISDN to use for duplicate threshold alert notification.

Select the duplicate thresholds at which to send alert notifications to the MSISDN.

For the duplicate threshold to be able to send an alert notification to the MSISDN, the duplicate message threshold alert notification action must be enabled and configured.

Configuring GTP on FortiOS Carrier

Configuring GTP support on FortiOS Carrier involves configuring a number of areas of features. Some features require longer explanations, and have their own chapters. The other features are addressed here.

GTP support on the Carrier-enabled FortiGate unit

The FortiCarrier unit needs to have access to all traffic entering and exiting the carrier network for scanning, filtering, and logging purposes. This promotes one of two configurations — hub and spoke, or bookend.

A hub and spoke configuration with the Carrier-enabled FortiGate unit at the hub and the other GPRS devices on the spokes is possible for smaller networks where a lower bandwidth allows you to divide one unit into multiple virtual domains to fill multiple roles on the carrier network. It can be difficult with a single FortiOS Carrier as the hub to ensure all possible entry points to the carrier network are properly protected from potential attacks such as relayed network attacks.

A bookend configuration uses two Carrier-enabled FortiGate units to protect the carrier network between them with high bandwidth traffic. One unit handles traffic from mobile stations, SGSNs, and foreign carriers. The other handles GGSN and data network traffic. Together they ensure the network is secure.

The Carrier-enabled FortiGate unit can access all traffic on the network. It can also verify traffic between devices, and verify that the proper GPRS interface is being used. For example there is no reason for a Gn interface to be used to communicate with a mobile station — the mobile station will not know what to do with the data — so that traffic is blocked.

When you are configuring your Carrier-enabled FortiGate unit's GTP profile, you must first configure the APN. It is critical to GTP communications — no traffic will flow without the APN.

The Carrier-enabled FortiGate unit does more than just forward and route GTP packets over the network. It also performs:

- Packet sanity checking
- GTP stateful inspection
- Protocol anomaly detection and prevention
- HA
- Virtual domain support

Packet sanity checking

The FortiOS Carrier firewall checks the following items to determine if a packet confirms to the UDP and GTP standards:

- GTP release version number — must be 0, 1, or 2
- Settings of predefined bits
- Protocol type
- UDP packet length

If the packet in question does not confirm to the standards, the FortiOS Carrier firewall drops the packet, so that the malformed or forged traffic will not be processed.

GTP stateful inspection

Apart from the static inspection (checking the packet header), the FortiOS Carrier firewall performs stateful inspection.

Stateful inspection provides enhanced security by keeping track of communications sessions and packets over a period of time. Both incoming and outgoing packets are examined. Outgoing packets that request specific types of incoming packets are tracked; only those incoming packets constituting a proper response are allowed through the firewall.

The FortiOS Carrier firewall can also index the GTP tunnels to keep track of them.

Using the enhanced Carrier traffic policy, the FortiOS Carrier firewall can block unwanted encapsulated traffic in GTP tunnels, such as infrastructure attacks. Infrastructure attacks involve attempts by an attacker to connect to restricted machines, such as GSN devices, network management systems, or mobile stations. If these attmpts to connect are detected, they are to be flagged immediately by the firewall .

Protocol anomaly detection and prevention

The FortiOS Carrier firewall detects and optionally drops protocol anomalies according to GTP standards and specific tunnel states. Protocol anomaly attacks involve malformed or corrupt packets that typically fall outside of protocol specifications. These packets are not seen on a production network. Protocol anomaly attacks exploit poor programming practices when decoding packets, and are typically used to maliciously impair system performance or elevate privileges.

FortiOS Carrier also detects IP address spoofing inside GTP data channel.

See Configuring the Protocol Anomaly feature in FortiOS Carrier.

HA

FortiOS Carrier active-passive HA provides failover protection for the GTP tunnels. This means that an active-passive cluster can provide FortiOS Carrier firewall services even when one of the cluster units encounters a problem that would result in complete loss of connectivity for a stand-alone FortiOS Carrier firewall. This failover protection provides a backup mechanism that can be used to reduce the risk of unexpected downtime, especially for mission-critical environments.

FortiOS HA synchs TCP sessions by default, but UDP sessions are not synchronized by default. However synchronizing a session is only part of the solution if the goal is to continue GTP processing on a synchronized session after a HA switch. For that to be successful we also need to synch the GTP tunnel state. So, once the master completes tunnel setup then the GTP tunnel is synchronized to the slave.

GTP traffic will only flow without interruption on a HA switch if bidirectional GTP policies have been configured: an internal (GTP server) to external (all) UDP port GTP policy, and an external (all) to internal (GTP server) UDP port GTP policy. If either policy is missing then traffic may be interrupted until traffic flows in the opposite direction.

For more information on HA in FortiOS, see the High Availability (HA) Guide or the FortiOS Administration Guide.

Virtual domain support

FortiOS Carrier is suited to both large and smaller carriers. A single Carrier-enabled FortiGate unit can serve either one large carrier, or several smaller ones through virtual domains. As with any FortiGate unit, Carrier-enabled units have the ability to split their resources into multiple virtual units. This allows smaller carriers to use just the resources that they need without wasting the extra. For more information on HA in FortiOS, see the Virtual Domains (VDOMs) Guide.

Configuring General Settings on the Carrier-enabled FortiGate unit

To configure the GTP General Settings, go to **Security Profiles > Carrier > GTP Profile**, and edit a GTP profile. Expand **General Settings** to configure settings. See General settings options

GTP Monitor Mode

The `monitor-mode` setting is part of the GTP profile. The setting shows on all GTP profiles and works for all GTP versions.

When this setting is enabled, if a GTP packet is to be dropped due to a GTP deny case such as:

- GTP_DENY
- GTP_RATE_LIMIT
- GTP_STATE_INVALID
- GTP_TUNNEL_LIMIT

instead of being dropped, it will be forwarded and logged with the original deny log message and a "-monitor" suffix (e.g., state-invalid-monitor).

This setting is found in the CLI.

```
config firewall gtp
   edit profile_name
      ...
      set monitor-mode [disable*|enable]
```

```
    ...
    end
end
```

Configuring Encapsulated Filtering in FortiOS Carrier

Encapsulated traffic on the GPRS network can come in a number of forms as it includes traffic that is “wrapped up” in another protocol. This detail is important for firewalls because it requires “unwrapping” to properly scan the data inside. If encapsulated packets are treated as regular packets, that inside layer will never be scanned and may allow malicious data into your network.

On Carrier-enabled FortiGate units, GTP related encapsulated filtering falls under encapsulated IP traffic filtering, and encapsulated non-IP end user address filtering.

Configuring Encapsulated IP Traffic Filtering

Generally there are a very limited number of IP addresses that are allowed to encapsulate GPRS traffic. For example GTP tunnels are a valid type of encapsulation when used properly. This is the GTP tunnel which uses the Gp or Gn interfaces between SGSNs and GGSNs. However, a GTP tunnel within a GTP tunnel is not accessible — FortiOS Carrier will either block or forward the traffic, but is not able to open it for inspection.

The ability to filter GTP sessions is based on information contained in the data stream and provides operators with a powerful mechanism to control data flows within their infrastructure. You can also configure IP filtering rules to filter encapsulated IP traffic from Mobile Stations.

To configure the Encapsulated IP Traffic Filtering, go to **Security Profiles > Carrier > GTP Profile**, and edit a GTP profile. Expand **Encapsulated IP Traffic Filtering** to configure settings. See Encapsulated IP traffic filtering options.

When to use encapsulated IP traffic filtering

The following are the typical cases that need encapsulated IP traffic filtering:

Mobile station IP pools

In a well-designed network, best practices dictate that the mobile station address pool is to be completely separate from the GPRS network infrastructure range of addresses. Encapsulated IP packets originating from a mobile station will not contain source or destination addresses that fall within the address range of GPRS infrastructures. In addition, traffic originating from the users handset will not have destination/source IP addresses that fall within any Network Management System (NMS) or Charging Gateway (CG) networks.

Communication between mobile stations

Mobile stations on the same GPRS network are not able to communicate with other mobile stations. Best practices dictate that packets containing both source and destination addresses within the mobile station's range of addresses are to be dropped.

Direct mobile device or internet attacks

It may be possible for attackers to wrap attack traffic in GTP protocols and submit the resulting GTP traffic directly to a GPRS network element from their mobile stations or a node on the Internet. It is possible that the receiving SGSN or GGSN would then strip off the GTP header and attempt to route the underlying attack. This

underlying attack could have any destination address and would probably have a source address spoofed as if it were valid from that PLMN.

You cannot add an IE removal policy when you are creating a new profile.

Relayed network attacks

Depending on the destination the attack could be directly routed, such as to another node of the PLMN, or rewrapped in GTP for transmission to any destination on the Internet outside the PLMN depending on the routing table of the GSN enlisted as the unwitting relay.

The relayed attack could have any source or destination addresses and could be any of numerous IP network attacks, such as an attack to hijack a PDP context, or a direct attack against a management interface of a GSN or other device within the PLMN. Best practices dictate that any IP traffic originating on the Internet or from an MS with a destination address within the PLMN is to be filtered.

Configuring Encapsulated Non-IP End User Address Filtering

Much of the traffic on the GPRS network is in the form of IP traffic. However some parts of the network do not used IP based addressing, so the Carrier-enabled FortiGate unit is unable to perform Encapsulated IP Traffic Filtering.

Depending on the installed environment, it may be beneficial to detect GTP packets that encapsulate non-IP based protocols. You can configure the FortiOS Carrier firewall to permit a list of acceptable protocols, with all other protocols denied.

The encoded protocol is determined in the PDP Type Organization and PDP Type Number fields within the End User Address Information Element. The PDP Type Organization is a 4-bit field that determines if the protocol is part of the ETSI or IETF organizations. Values are zero and one, respectively. The PDP Type field is one byte long. Both GTP specifications only list PPP, with a PDP Type value of one, as a valid ETSI protocol. PDP Types for the IETF values are determined in the "Assigned PPP DLL Protocol Numbers" sections of RFC 1700. The PDP types are compressed, meaning that the most significant byte is skipped, limiting the protocols listed from 0x00 to 0xFF.

To configure the Encapsulated Non-IP End User Address Filtering, go to **Security Profiles > Carrier > GTP Profile**, and edit a GTP profile. Expand **Encapsulated Non-IP End User Address Filtering** to configure settings. See Encapsulated non-IP end user traffic filtering options.

Configuring the Protocol Anomaly feature in FortiOS Carrier

When anomalies do happen, it is possible for the anomaly to interrupt network traffic or consume network resources — if precautions are not taken. Anomalies can be generated by accident or maliciously, but both methods can have the same results — degrading the performance of the carrier network, or worse.

To configure GTP protocol anomalies, go to **Security Profiles > Carrier > GTP Profile**, and edit a GTP profile. Expand the **Protocol Anomaly** option. SeeProtocol Anomaly prevention options.

The following are some examples:

- The GTP header specifies the length of the packet excluding the mandatory GTP header. In GTP version 0 (GSM 09.60), the mandatory GTP header size is 20 bytes, whereas GTP version 1 (GSM 29.060) specifies that the

minimum length of the GTP header is 8 bytes. The GTP packet is composed of the header, followed by Information Elements typically presented in a Type-Length-Value format. It is possible for an attacker to create a GTP packet with a GTP header field length that is incompatible with the length of the necessary information elements.

- The same concepts are true for GTP version 2 headers even though there are different fields in them.
- It is similarly possible for an attacker to create a packet with an invalid IE length. Invalid lengths may cause protocol stacks to allocate incorrect amounts of memory, and thereby cause crashes or buffer overflows.

By default the FortiOS Carrier firewall detects these problems, as well as other protocol anomalies, and drops the packets. All protocol anomaly options are set to **Deny** by default. However, you can change the policy to allow them.

Configuring Anti-overbilling in FortiOS Carrier

GPRS overbilling attacks can be prevented with a properly configured Carrier-enabled FortiGate unit.

Overbilling can occur when a subscriber returns his IP address to the IP pool. Before the billing server closes it, the subscriber's session is still open and vulnerable. If an attacker takes control of the subscriber's IP address, he can send or receive data and the subscriber will be billed for the traffic.

Overbilling can also occur when an available IP address is reassigned to a new mobile station (MS). Subsequent traffic by the previous MS may be forwarded to the new MS. The new MS would then be billed for traffic it did not initiate.

Anti-overbilling with FortiOS Carrier

The Carrier-enabled FortiGate unit can be configured to assist with anti-overbilling measures. These measures ensure that the customer is only billed for connection time and data transfer that they actually use.

Anti-overbilling on the Carrier-enabled FortiGate unit involves:

- the administrator configuring the overbilling settings in the GTP profile to notify the Gi firewall when a GTP tunnel is deleted
- the unit clearing the sessions when the Gi firewall receives a notification from the Gn/Gp firewall about a GTP tunnel being deleted This way, the Gi firewall prevents overbilling by blocking traffic initiated by other users.

The three locations to configure anti-overbilling options include:

- **System > Network > Interface > Gi Gatekeeper** — edit an interface, and enable to monitor Gi anti-overbilling traffic on this interface
- **System > Admin > Settings > Gi Gatekeeper Settings** — set the context ID and port that anti-overbilling will take place on.
- **Security Profiles > Carrier > GTP Profile > Anti-Overbilling** — the IP address, port, interface and context ID to use for anti-overbilling measures.

For detailed options, see Anti-Overbilling options.

Logging events on the Carrier-enabled FortiGate unit

Logging on the Carrier-enabled FortiGate unit is just like logging on any other FortiOS unit. The only difference with FortiOS Carrier is that there are a few additional events that you can log beyond the regular ones. These additional events are covered here.

To enable FortiOS Carrier logging, go to **Log&Report > Event Log**, and ensure **GTP service event** is enabled. Once this option is selected, the logging options under **Security Profiles > Carrier > GTP Profile** will be active.

To change FortiOS Carrier specific logging event settings, go to **Security Profiles > Carrier > GTP Profile** and edit a GTP profile. Expand the **Log** section to change the settings. For detailed options, see Log options.

The following information is contained in each log entry:

Timestamp	The time and date when the log entry was recorded
Source IP address	The sender's IP address.
Destination IP address	The reciever's IP address. The sender-receiver pair includes a mobile phone on the GPRS local network, and a device on a network external to the GPRS network, such as the Internet.
Tunnel Identifier (TID) **Tunnel Endpoint Identifier (TEID)**	An identifier for the start and endpoints of a GTP tunnel. This information uniquely defines all tunnels. It is important for billing information based on the length of time the tunnel was active and how much data passed over the tunnel.
Message type	For available message types, see Common message types on carrier networks.
Packet status	What action was performed on the packet. This field matches the logging options while you are configuring GTP logging. See Anti-overbilling with FortiOS Carrier on page 999. The status can be one of forwarded, prohibited, state-invalid, rate-limited, or tunnel-limited
Virtual domain ID or name	A Carrier-enabled FortiGate unit can be divided into multiple virtual units, each being a complete and self-contained virtual FortiCarrier unit. This field indicates which virtual domain (VDOM) was responsible for the log entry. If VDOMs are not enabled on your unit, this field will be `root`.
Reason to be denied if applicable	If the packet that generated this log entry was denied or blocked, this field will include what part of FortiOS denied or blocked that packet. Such as firewall, antivirus, webfilter, or spamfilter.

An example of the above log message format is for a Tunnel deleted log entry. When a tunnel is deleted, the log entry contains the following information:

- Timestamp
- Interface name (if applicable)
- SGSN IP address (source IP)
- GGSN IP address (destination IP)
- Tunnel ID
- Tunnel duration time in seconds

- Number of messages sent to the SGSN
- Number of messages sent to the GGSN

GTP message type filtering

FortiOS Carrier supports message filtering in GTP by the type of message.

This section includes:

Common message types on carrier networks

Carrier networks include many types of messages — some concern the network itself, others are content moving across the network, and still others deal with handshaking, billing, or other administration based issues.

GTP contains two major parts GTP for the control plane (GTP-C) and GTP for user data tunnelling (GTP-U). Outside of those areas there are only unknown message types.

GTP-C messages

GTP-C contains the networking layer messages. These address routing, versioning, and other similar low level issues.

When a subscriber requests a Packet Data Protocol (PDP) context, the SGSN will send a create PDP context request GTP-C message to the GGSN giving details of the subscriber's request. The GGSN will then respond with a create PDP context response GTP-C message which will either give details of the PDP context actually activated or will indicate a failure and give a reason for that failure. This is a UDP message on port 212.

GTP-C message types include Path Management Messages, Location Management Messages, and Mobility Management Messages.

Path Management Messages

Path management is used by one GSN to detect if another GSN is alive, or if it has restarted after a failure.

The path management procedure checks if a given GSN is alive or has been restarted after a failure. In case of SGSN restart, all MM and PDP contexts are deleted in the SGSN, since the associated data is stored in a volatile memory. In the case of GGSN restart, all PDP contexts are deleted in the GGSN.

Tunnel Management Messages

The tunnel management procedures are used to create, update, and delete GTP tunnels in order to route IP PDUs between an MS and an external PDN via the GSNs.

The PDP context contains the subscriber's session information when the subscriber has an active session. When a mobile wants to use GPRS, it must first attach and then activate a PDP context. This allocates a PDP context data structure in the SGSN that the subscriber is currently visiting and the GGSN serving the subscriber's access point.

Tunnel management procedures are defined to create, update, and delete tunnels within the GPRS backbone network. A GTP tunnel is used to deliver packets between an SGSN and a GGSN. A GTP tunnel is identified in each GSN node by a TEID, an IP address, and a UDP port number.

Location Management Messages

The location-management procedure is performed during the network-requested PDP context activation procedure if the GGSN does not have an SS7 MAP interface (i.e., Gc interface). It is used to transfer location messages between the GGSN and a GTP-MAP protocol-converting GSN in the GPRS backbone network.

Location management subprocedures are used between a GGSN that does not support an SS7 MAP interface (i.e., Gc interface) and a GTP-MAP protocol-conversing GSN. This GSN supports both Gn and Gc interfaces and is able to perform a protocol conversing between GTP and MAP.

Mobility Management Messages

The MM procedures are used by a new SGSN in order to retrieve the IMSI and the authentication information or MM and PDP context information in an old SGSN. They are performed during the GPRS attach and the inter-SGSN routing update procedures.

The MM procedures are used between SGSNs at the GPRS-attach and inter-SGSN routing update procedures. An identity procedure has been defined to retrieve the IMSI and the authentication information in an old SGSN. This procedure may be performed at the GPRS attach. A recovery procedure enables information related to MM and PDP contexts in an old SGSN to be retrieved. This procedure is started by a new SGSN during an inter-SGSN RA update procedure.

GTP-U messages

GTP-U is focused on user related issues including tunneling, and billing. GTP-U message types include MBMS messages, and GTP-U and Charging Management Messages

MBMS messages

Multimedia Broadcast and Multicast Services (MBMS) have recently begun to be offered over GSM and UMTS networks on UTRAN and GERAN radio access technologies. MBMS is mainly used for mobile TV, using up to four GSM timeslots for one MBMS connection. One MBMS packet flow is replicated by GGSN, SGSN and RNCs.

MBMS is split into the MBMS Bearer Service and the MBMS User Service. The MBMS User Service is basically the MBMS Service Layer and offers a Streaming- and a Download Delivery Method. The Streaming Delivery method can be used for continuous transmissions like Mobile TV services. The Download Method is intended for "Download and Play" services.

GTP-U and Charging Management Messages

SGSNs and GGSNs listen for GTP-U messages on UDP port 2152.

GTP‘ (GTP prime) is used for billing messages. It uses the common GTP messages (GTP Version Not Supported, Echo Request and Echo Response) and adds additional messages related to billing procedures.

Unknown Action messages

If the system doesn’t know what type of message it is, it falls into this category. This is an important category of message because malformed messages may appear and need to be handled with security in mind.

Fortinet best practices dictate that you set **Unknown Action messages** to deny for security reasons.

Configuring message type filtering in FortiOS Carrier

GPRS Tunnelling Protocol (GTP) is a group of IP-based communications protocols used to carry General Packet Radio Service (GPRS) traffic within Global System for Mobile Communications (GSM) and Universal Mobile Telecommunications System (UMTS) networks. It allows carriers to transport actual cellular packets over their network via tunneling.

In the CLI, there is a keyword for each type of GTP message for both message filtering, and for message rate limiting.

GTP message rate limiting is only accessible from the CLI using the command `configure firewall gtp`.

To configure GTP message type filtering - web-based manager

1. Go to **Security Profiles > GTP Profile**.
2. Select **Create New**.
3. Enter a name for this profile such as `msg_type_filtering`.
4. Select **Message Type Filtering** to expand it.
5. For each type of message in the list, select Allow or Deny. All messages are set to Allow by default.

Fortinet best practices dictate that the unknown message action should be set to **Deny** for security reasons as this will block malformed messages.

6. Optionally select and configure any other GTP features for this profile, such as logging.
7. Select **OK** to save the profile.
8. Apply the `msg_type_filtering` profile a security policy configured for GTP tunnel traffic.

To configure GTP message filtering and block Unknown Message Action messages- CLI

```
config firewall gtp
   edit msg_type_filtering
      config message-filter
         set unknown-message-action deny
      next
   end
end
```

Message Type Fields

Each of the following message types can be allowed or denied by your Carrier-enabled FortiGate unit depending on your carrier network and GTP traffic.

Unknown Message Action

Set this message type to deny.

Many attempts to hack into a carrier network will result in this unknown message type and therefore it is denied for security reasons.

Path Management Messages

Message Type	Used by	Description
Echo Request/Response	GTP-C, GTP-U, GTP'	Echo Request is sent on a path to another GSN to determine if the other node is alive. Echo Response is the reply.
Version not Supported	GTP-C, GTP-U, GTP'	There are multiple versions of GTP. Both devices communicating must use the same version of GTP, or this message will be the response.
Support Extension Headers Notification		Extensions are optional parts that a device can choose to support or not. If a device includes these extensions, it must include headers for the extensions to sure ensure proper formatting.

Tunnel Management Messages

Message Type	Used by	Description
Create PDP Context Request/ Response	GTP-C	Sent from an SGSN to a GGSN node as part of a GPRS PDP Context Activation procedure or the Network-Requested PDP Context Activation procedure. A valid request initiates the creation of a tunnel.
Update PDP Context Request/ Response	GTP-C	Used when PDP Context information changes, such as when a mobile device changes location.
Delete PDP Context Request/ Response	GTP-C	Used to terminate a PDP Context, and confirm the context has been deleted.
Create AA PDP Context Request/ Response	GTP-C	Sent as part of the GPRS Anonymous Access PDP Context Activation. It is used to create a tunnel between a context in the SGSN and a context in the GGSN.
Delete AA PDP Context Request/ Response	GTP-C	Sent as part of the GPRS PDP Anonymous Access Context Deactivation procedure to deactivate an activated PDP Context. It contains Cause and Private Extension Information Elements

Message Type	Used by	Description
Error Indication	GTP-U	Sent to the GGSN when a tunnel PDU is received for the following conditions: — No PDP context exists — PDP context is inactive — No MM context exists — GGSN deletes its PDP context when the message is received.
PDU Notification Request/ Response/ Reject Request/ Reject Response	GTP-C	When receiving a Tunneled PDU (T-PDU), the GGSN checks if a PDP context is established for the given PDP address. If no PDP context has been established, the GGSN may initiate the Network-requested PDP Context Activation procedure by sending a PDU Notification Request to the SGSN. **Reject Request -** Sent when the PDP context requested by the GGSN cannot be established.

Location Management Messages

Message Type	Used By	Description
Send Routing Information for GPRS Request/ Response	GTP-C	Sent by the GGSN to obtain location information for the MS. This message type contains the IMSI of the MS and Private Extension.
Failure Report Request/ Response	GTP-C	Sent by the GGSN to the HLR when a PDU reject message is received. The GGSN requests the HLR to set the flag and add the GGSN to the list of nodes to report to when activity from the subscriber that owns the PDP address is detected. The message contains the subscriber IMSI and Private Extension
Note MS GPRS Present Request/ Response	GTP-C	When the HLR receives a message from a mobile with MDFG set, it clears the MDFG and sends the Note MS Present message to all GGSN's in the subscriber's list. This message type contains subscriber IMSI, GSN Address and Private Extension

Mobility Management Messages

Message Type	Used By	Description
Identification Request/Response	GTP-C	Sent by the new SGSN to the old SGSN to request the IMSI for a MS when a GPRS Attach is done with a P-TMSI and the MS has changed SGSNs since the GPRS Detach was done.
SGSN context Request/ Response/ Acknowledge	GTP-C	Sent by the new SGSN to the old SGSN to request the MM and PDP Contexts for the MS.
Forward Relocation Request/ Response/ Complete/ Complete Acknowledge	GTP-C	Indicates mobile activation/deactivation within a Routing Area. This prevents paging of a mobile that is not active (visited VLR rejects calls from the HLR or applies Call Forwarding). Note that the mobile station does not maintain an attach/detach state. SRNS contexts contain for each concerned RAB the sequence numbers of the GTP-PDUs next to be transmitted in uplink and downlink directions.
Relocation Cancel Request/ Response	GTP-C	Send to cancel the relocation of a connection.
Forward SRNS Context/ Context Acknowledge	GTP-C	This procedure may be used to trigger the transfer of SRNS contexts from RNC to CN (PS domain) in case of inter system forward handover.
RAN Information Relay	GTP-C	Forward the Routing Area Network (RAN) information. A Routing Area (RA) is a subset of a GSM Location Area (LA). A RA is served by only one SGSN. Ensures that regular radio contact is maintained by the mobile

MBMS messages

Message Type	Used By	Description
MBMS Notification Request/ Response/ Reject Request/ Reject Response	GTP-C	Notification of the radio access devices.
Create MBMS Context Request/ Response	GTP-C	Request to create an active MBMS context. The context will be pending until the response is received. Once active, the MBMS context allows the MS to receive data from a specific MBMS source

Message Type	Used By	Description
Update MBMS Context Request/ Response	GTP-C	
Delete MBMS Context Request/ Response	GTP-C	Request to deactivate the MBMS context. When the response is received, the MBMS context will be inactive.

GTP-U and Charging Management Messages

Message Type	Used By	Description
G-PDU	GTP-C, GTP-U	GPRS Packet data unit delivery message.
Node Alive Request/Response	GTP-C, GTP-U	Used to inform rest of network when a node starts service.
Redirection Request/Response	GTP-C, GTP-U	Used to divert the flow of CDRs from the CDFs to another CGF when the sender is being removed, or they are used when the CGF has lost its connection to a downstream system.
Data Record Transfer Request/Response	GTP-C, GTP-U	Used to reliably transport CDRs from the point of generation (SGSN/GGSN) to non-volatile storage in the CGF

GTP identity filtering

FortiOS Carrier supports a number of filtering methods based on subscriber identity such as APN filtering, IMSI filtering, and advanced filtering.

This section includes:

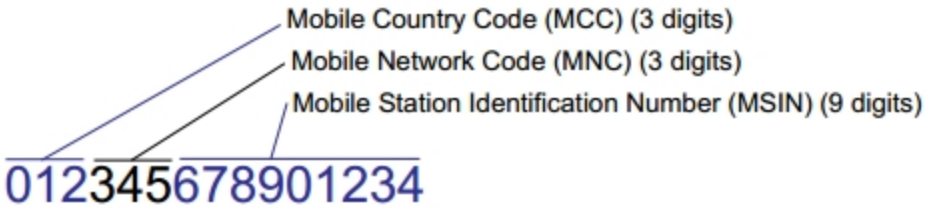
IMSI on carrier networks

The International Mobile Subscriber Identity (IMSI) number is central to identifying users on a carrier network. It is a unique number that is assigned to a cell phone or mobile device to identify it on the GMS or UTMS network.

Typical the IMSI number is stored on the SIM card of the mobile device and is sent to the network as required.

An IMSI number is 15 digits long, and includes the Mobile Country Code (MCC), Mobile Network Code (MNC), and Mobile Station Identification Number (MSIN).

IMSI codes



The Home Network Identity (HNI) is made up of the MCC and MNC. The HNI is used to fully identify a user's home network. This is important because some large countries have more than one country code for a single carrier. For example a customer with a mobile carrier on the East Coast of the United States would have a different MCC than a customer on the West Coast with the same carrier because even through the MNC would be the same the MCC would be different — the United States uses MCCs 310 to 316 due to its size.

If an IMSI number is not from the local carrier's network, IMSI analysis is performed to resolve the number into a Global Title which is used to access the user's information remotely on their home carrier's network for things like billing and international roaming.

Other identity and location based information elements

IMSI focuses on the user, their location, and carrier network. There are other numbers used to identify different user related Information Elements (IE).

These identity and location based elements include:

- Access Point Number (APN)
- Mobile Subscriber Integrated Services Digital Network (MSISDN)
- Radio Access Technology (RAT) type
- User Location Information (ULI)

- Routing Area Identifier (RAI)
- International Mobile Equipment Identity (IMEI)

Access Point Number (APN)

The Access Point Number (APN) is used in GPRS networks to identify an IP packet data network that a user wants to communicate with. The Network Identifier describes the network and optionally the service on that network that the GGSN is connected to. The APN also includes the MCC and MCN, which together locate the network the GGSN belongs to. An example of an APN in the Barbados using Digicel as the carrier that is connecting to the Internet is `internet.mcc342.mnc750.gprs`.

When you are configuring your Carrier-enabled FortiGate unit's GTP profiles, you must first configure the APN. It is critical to GTP communications and without it no traffic will flow.

The access point can then be used in a DNS query to a private DNS network. This process (called APN resolution) gives the IP address of the GGSN which serves the access point. At this point a PDP context can be activated.

Mobile Subscriber Integrated Services Digital Network (MSISDN)

This is a 15-digit number that, along with the IMSI, uniquely identifies a mobile user. Normally this number includes a 2-digit country code, a 3-digit national destination code, and a 10-digit subscriber number or the phone number of the mobile device, and because of that may change over time if the user changes their phone number. The MSISDN number follows the ITU-T E.164 numbering plan.

Radio Access Technology (RAT) type

The RAT type represents the radio technology used by the mobile device. This can be useful in determining what services or content can be sent to a specific mobile device. FortiOS Carrier supports:

- **UMTS Terrestrial Radio Access Network (UTRAN)**, commonly referred to as 3G, routes many types of traffic including IP traffic. This is one of the faster types.
- **GSM EDGE Radio Access Network (GERAN)** is a key part of the GSM network which routes both phone calls and data.
- **Wireless LAN (WLAN)** is used but not as widely as the other types. It is possible for the mobile device to move from one WLAN to another such as from an internal WLAN to a commercial hot spot.
- **Generic Access Network (GAN)** can also be called unlicensed mobile access (UMA). It routes voice, data, and SIP over IP networks. GAN is commonly used for mobile devices that have a dual-mode and can hand-off between GSM and WLANs.
- **High Speed Packet Access (HSPA)** includes two other protocols High Speed Downlink and Uplink Packet Access protocols (HSDPA and HSUPA respectively). It improves on the older WCDMA protocols by better using the radio bandwidth between the mobile device and the radio tower. This results in an increased data transfer rate for the user.

RAT type is part of advanced filtering configuration. See Configuring advanced filtering in FortiOS Carrier.

User Location Information (ULI)

Gives Cell Global Identity/Service Area Identity (CGI/SAI) of where the mobile station is currently located. The ULI and the RAI are commonly used together to identify the location of the mobile device.

ULI is part of advanced filtering configuration. See Configuring advanced filtering in FortiOS Carrier.

Routing Area Identifier (RAI)

Routing Areas (RAs) divide the carrier network and each has its own identifier (RAI). When a mobile device moves from one routing area to another, the connection is handled by a different part of the network. There are normally multiple cells in a routing area. There is only one SSGN per routing area. The RAI and ULI are commonly used to determine a user's location.

RAI is part of advanced filtering configuration. See Configuring advanced filtering in FortiOS Carrier.

International Mobile Equipment Identity (IMEI)

IMEI is a unique 15-digit number used to identify mobile devices on mobile networks. It is very much like the MAC address of a TCP/IP network card for a computer. It can be used to prevent network access by a stolen phone — the carrier knows the mobile phone's IMEI, and when it is reported stolen that IMEI is blocked from accessing the carrier network no matter if it has the same SIM card as before or not. It is important to note that the IMEI stays with the mobile phone or device where the other information is either location based or stored on the removable SIM card.

IMEI type is part of advanced filtering configuration. See Configuring advanced filtering in FortiOS Carrier.

When to use APN, IMSI, or advanced filtering

At first glance APN, IMSI, and advanced filtering have parts in common. For example two can filter on APN, and another two can filter on IMSI. The difficulty is knowing when to use which type of filtering.

Identity filtering comparison

Filtering type	Filter on the following data:	When to use this type of filtering
APN	APN	Filter based on GTP tunnel start or destination
IMSI	IMSI, MCC-MNC	Filter based on subscriber information
Advanced	PDP context, APN, IMSI, MSISDN, RAT type, ULI, RAI, IMEI	When you want to filter based on: • user phone number (MSISDN) • what wireless technology the user employed • to get on the network (RAT type) • user location (ULI and RAI) • handset ID, such as for stolen phones (IMEI)

APN filtering is very specific — the only identifying information that is used to filter is the APN itself. This will always be present in GTP tunnel traffic, so all GTP traffic can be filtered using this value.

IMSI filtering can use a combination of the APN and MCC-MNC numbers. The MCC and MNC are part of the APN, however filtering on MCC-MNC separately allows you to filter based on country and carrier instead of just the destination of the GTP Tunnel.

Advanced filtering can go into much deeper detail covering PDP contexts, MSISDN, IMEI, and more not to mention APN, and IMSI as well. If you can't find the information in APN or IMSI that you need to filter on, then use Advanced filtering.

Configuring APN filtering in FortiOS Carrier

To configure APN filtering go to **Security Profiles > GTP Profile**. Select a profile or create a new one, and expand **APN filtering**.

When you are configuring your Carrier-enabled FortiGate unit's GTP profiles, you must first configure the APN. It is critical to GTP communications and without it no traffic will flow.

Enable APN Filter	Select to enable filtering based on APN value.
Default APN Action	Select either Allow or Deny for all APNs that are not found in the list. The default is Allow.
Value	Displays the APN value for this entry. Partial matches are allowed using wildcard. For example `*.mcc333.mcn111.gprs` would match all APNs from country `333` and carrier `111` on the gprs network.
Mode	Select one or more of the methods used to obtain APN values. Mobile Station provided - The APN comes from the mobile station where the mobile device connected. This is the point of entry into the carrier network for the user's connection. Network provided - The APN comes from the carrier network. Subscription Verified - The user's subscription has been verified for this APN. This is the most secure option.
Action	One of allow or deny to allow or block traffic associated with this APN.
Delete icon	Select to remove this APN entry from the list.
Edit icon	Select to change the information for this APN entry.
Add APN	Select to add an APN to the list. Not active while creating GTP profile, only when editing an existing GTP profile. Save all changes before adding APNs. A warning to this effect will be displayed when you select the **Add APN** button.

The Add APN button is not activated until you save the new GTP profile. When you edit that GTP profile, you will be able to add new APNs.

Configuring IMSI filtering in FortiOS Carrier

In many ways the IMSI on a GPRS network is similar to an IP address on a TCP/IP network. Different parts of the number provide different pieces of information. This concept is used in IMSI filtering on FortiOS Carrier.

To configure IMSI filtering go to **Security Profiles > GTP Profile** and expand **IMSI filtering**.

While both the APN and MCC-MCN fields are optional, without using one of these fields the IMSI entry will not be useful as there is no information for the filter to match.

Enable IMSI Filter	Select to turn on IMSI filtering.
Default IMSI Action	Select Allow or Deny. This action will be applied to all IMSI numbers except as indicated in the IMSI list that is displayed. The default value is Allow.
APN	The Access Point Number (APN) to filter on. This field is optional.
MCC-MNC	The Mobile Country Code (MCC) and Mobile Network Code (MNC) to filter on. Together these numbers uniquely identify the carrier and network of the GGSN being used. This field is optional.
Mode	Select the source of the IMSI information as one or more of the following: **Mobile Station provided -** the IMSI number comes from the mobile station the mobile device is connecting to. **Network provided -** the IMSI number comes from the GPRS network which could be a number of sources such as the SGSN, or HLR. **Subscription Verified -** the IMSI number comes from the user's home network which has verified the information. While Subscription Verified is the most secure option, it may not always be available. Selecting all three options will ensure the most complete coverage.
Action	Select the action to take when this IMSI information is encountered. Select one of Allow or Deny.
Delete Icon	Select the delete icon to remove this IMSI entry.
Edit Icon	Select the edit icon to change information for this IMSI entry.

Add IMSI	Select to add an IMSI to the list. Not active while creating GTP profile, only when editing an existing GTP profile. Save all changes before adding IMSIs. A warning to this effect will be displayed when you select the **Add IMSI** button.

Configuring advanced filtering in FortiOS Carrier

Compared to ADN or IMSI filtering, advanced filtering is well named. Advanced filtering can be viewed as a catch-all filtering option — if ADN or IMSI filtering doesn't do what you want, then advanced filtering will. The advanced filtering can use more information elements to provide considerably more granularity for your filtering.

Enable	Select to turn on advanced filtering.
Default Action	Select Allow or Deny as the default action to take when traffic does not match an entry in the advanced filter list .
Messages	Optionally select one or more types of messages this filter applies to: Create PDP Context Request, Create PDP Context Response, Update PDP Context Request, or Update PDP Context Response. Selecting **Create PDP Context Response** or **Update PDP Context Response limits RAT type to only GAN and HSPA, and disables the APN, APN Mode, IMSI, MSISDN, ULI, RAI,** and **IMEI fields.** To select **Update PDP Context Request**, **APN Restriction** must be set to **all**. Selecting **Update PDP Context Request disables the APN, MSISDN,** and **IMEI fields.** if all message types are selected, only the RAT Types of GAN and HSPA are available to select.
APN Restriction	APN Restriction either allows all APNs or restricts the APNs to one of four categories — Public-1, Public-2, Private-1, or Private-2. This can also be combined with a specific APN or partial APN as well as specifying the APN mode.
RAT Type	Select one or more of the Radio Access Technology Types listed. These fields control how a user accesses the carrier's network. You can select one or more of UTRAN, GERAN, WLAN, GAN, HSPA, or any.
ULI	The user location identifier. Often the ULI is used with the RAI to locate a user geographically on the carrier's network. The ULI is disabled when **Create PDP Context Response** or **Update PDP Context Response** messages are selected.

RAI	The router area identifier. There is only one SGSN per routing area on a carrier network. This is often used with ULI to locate a user geographically on a carrier network. The RAI is disabled when **Create PDP Context Response** or **Update PDP Context Response** messages are selected.
IMEI	The International Mobile Equipment Identity. The IMEI uniquely identifies mobile hardware, and can be used to block stolen equipment. The IMEI is only available when **Create PDP Context Request** or no messages are selected.
Action	Select **Allow** or **Deny** as the action when this filter matches traffic. The default is Allow.
Delete Icon	Select to delete this entry from the list.
Edit Icon	Select to edit this entry.
Add	Select to add an advanced filter to the list. Not active while creating GTP profile, only when editing an existing GTP profile. Save all changes before adding advanced filters. A warning to this effect will be displayed when you select the **Add** button.

Troubleshooting

This section offers troubleshooting options for Carrier-related issues.

This section includes:

FortiOS Carrier diagnose commands

This section includes diagnose commands specific to FortiOS Carrier features such as GTP.

GTP related diagnose commands

This CLI command allows you to gain information on GTP packets, logs, statistics, and other information.

```
diag firewall gtp <command>
```

apn list <gtp_profile>	The APN list entries in the specified GTP profile
auth-ggsns show <gtp_profile>	The authorized GGSNs entries for the specified GTP profile. Any GGSNs not on this list will not be recognized.
auth-sgsns show <gtp_profile>	The authorized SGSNs list entries for the specified GTP profile. Any SGSNs not on this list will not be recognized.
handover-grp show <gtp_ profile>	The handover group showing the range of allowed handover group IP addresses. The handover group acts like a whitelist of allowed GTP addresses with a default deny at the end — if the GTP address is not on the list, it is denied.
ie-remove-policy list <gtp_ profile>	List of IE policies in the IE removal policy for this GTP profile. The information displayed includes the message count for this policy, the length of the SGSN, the list of IEs, and list of SGSN IP addresses.
imsi list <gtp_profile>	IMSI filter entries for this GTP profile. The information displayed includes the message count for this filter, length of the IMSI, the length of the APN and IMSI, and of course the IMSI and APN values.
invalid-sgsns-to-long list <gtp_ profile>	List of SGSNs that do not match the filter criteria. These SGSNs will be logged.
ip-policy list <gtp_profile>	List the IP policies including message count for each policy, the action to take, the source and destination IP addresses or ranges, and masks.
noip-policy <gtp_profile>	List the non-IP policies including the message count, which mode, the action to take, and the start and end protocols to be used by decimal number.

path {list | flush}	Select list or flush. List the GTP related paths in FortiOS Carrier memory. Flush the GTP related paths from memory.
policy list <gtp_policy>	The GTP advanced filter policy information for this GTP profile. The information displayed for each entry includes a count for messages matching this filter, a hexidecimal mask of which message types to match, the associated flags, action to take on a match, APN selection mode, MSISDN, RAT types, RAI, ULI, and IMEI.
profile list	Displays information about the configured GTP profiles. You will not be able to see the bulk of the information if you do not log the output to a file.
runtime-stat flush	Select to flush the GTP runtime statistics from memory.
stat	Display the GTP runtime statistics — details on current GTP activity. This information includes how many tunnels are active, how many GTP profiles exist, how many IMSI filter entries, how many APN filter entries, advanced policy filter entries, IE remove policy filter entries, IP policy filter entries, clashes, and dropped packets.
tunnel {list | flush}	Select one of list or flush. List lists all the GTP tunnels currently active. Flush clears the list of active GTP tunnels. This does not clear the clash counter displayed in the `stat` command.

Applying IPS signatures to IP packets within GTP-U tunnels

GTP-U (GTP user data tunnelling) tunnels carry user data packets, signalling messages and error information. GTP-U uses UDP port 2152. Carrier-enabled FortiGate units can apply IPS intrusion protection and detection to GTP-U user data sessions.

To apply IPS to GTP-U user data sessions, add an IPS Sensor to a profile and add the profile to a security policy that accepts GTP-U tunnels. The security policy Service field must be set to GTP or ANY to accept GTP-U packets.

The Carrier-enabled FortiGate unit intercepts packets with destination port 2152, removes the GTP header and handles the packets as regular IP packets. Applying an IPS sensor to the IP packets, the Carrier-enabled FortiGate unit can log attacks and pass or drop packets depending on the configuration of the sensor.

If the packet is GTP-in-GTP, or a nested tunnel, the packets are passed or blocked without being inspected.

To apply an IPS sensor to GTP-U tunnels

1. Go to **Security Profiles > Intrusion Protection** and select Create New (**+**) to add an IPS Sensor.
2. Configure the IPS Sensor to detect attacks and log, drop, or pass attack packets.

See the Intrusion Protection section of the FortiOS UTM Guide.

3. Go to **Policy & Objects > IPv4 Policy** and apply the IPS sensor to the security policy.
4. Go to **Policy & Objects > IPv4 Policy** and select Create New to add a security policy or select a security policy.
5. Configure the security policy to accept GTP traffic.

   In the security policy configure the source and destination settings to match the GTP traffic. Service to GTP or ANY so that the security policy accepts GTP traffic.
6. Select the GTP profile within the security policy.
7. Configure any other required security policy settings.
8. Select **OK** to save the security policy.

GTP packets are not moving along your network

When GTP packets are not getting to their destination, this could be caused by any one of a number of issues. General troubleshooting principals apply here.

The following sections provide some suggestions on how to troubleshoot this issue:

- Attempt to identify the section of your network with the problem
- Ensure you have an APN configured
- Check the logs and adjust their settings if required
- Check the routing table
- Perform a sniffer trace
- Generate specific packets to test the network

Attempt to identify the section of your network with the problem

The first step is to determine how widespread this problem is. Does it affect the whole GPRS network, or just one or two devices?

If the entire network is has this problem, the solution is likely a more general one such as ensuring the security policies allow GTP traffic to pass, the GTP profile specifies SSGNs and GSGNs, or ensuring the GTP general settings are not overly limiting.

If one part of the network is affected, the problem is more likely centered around configurations with those network devices specified such as the handover group, or authorized SGSNs/GGSNs. It is also possible that small portions of the network may have hardware related issues such as cabling or faulty hardware. This section does not address those issues, and assumes hardware is not the problem.

The handover group is a whitelist of GTP addresses allowed to handle GTP messages. If a device's address is not on this list, it will be denied.

Ensure you have an APN configured

When you configure your GTP profile, ensure you first configure the APN. Without it, there will be no flow of traffic. The APN is used in nearly all GTP communications and without it, the Carrier-enabled FortiGate unit doesn't have the information it needs.

Check the logs and adjust their settings if required

During normal operation, the log settings will show any problems on the network but may not provide the level of details required to fully troubleshoot the problem. The reason for this is that the level of detail required for troubleshooting would quickly overwhelm the daily logs without any real benefit.

GTP related events in the event log will have message IDs in the range 41216 to 41222. For more information on GTP log messages, see the Log Message Reference. For more information on logging in general, see the Logging and Reporting guide.

Once there is a problem to troubleshoot, check the logs to trace the traffic patterns and narrow down the possible sources of the problem. There may be enough detail for you to locate and fix the problem without changing the log settings.

Remember to set any changes you made to the log settings back to their original values when you are done troubleshooting. Otherwise, the amount of detail will overwhelm your logging.

However, if more detail is required you can change settings such as:

- Lower the Log Frequency number in GTP Profiles so fewer or no log messages are dropped. This will allow a more accurate picture of everything happening on the network, where you may have had only a partial picture before.
- Ensure all the GTP log events are enabled to provide you with a complete picture.
- Ensure that all relevant event types are enabled under **Log & Report > Log Config > Log Settings.**

For more information on GTP related logging, see Logging events on the Carrier-enabled FortiGate unit.

General information to look for in the logs includes:

- Are all packets having problems or just certain types?
- Are all devices on the network having problem, or just certain devices?
- Is it just GTP traffic that is having problems or are all types of traffic having the same problem?

Check the routing table

On any network, the routing table determines how packets reach their destination. This is also true on a carrier network.

If the Carrier-enabled FortiGate unit is running in NAT mode, verify that all desired routes are in the routing table — local subnets, default routes, specific static routes, and dynamic routing protocols. For complete information, it is best to check the routing table in the CLI. This method provides more complete information.

If VDOMs are enabled on your Carrier-enabled FortiGate unit, all routing related CLI commands must be performed within a VDOM and not in the global context.

To check the routing table using the CLI

```
# get router info routing-table all
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
O - OSPF, IA - OSPF inter area
N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
E1 - OSPF external type 1, E2 - OSPF external type 2
```

```
i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
* - candidate default

S* 0.0.0.0/0 [10/0] via 192.168.183.254, port2
S 1.0.0.0/8 [10/0] via 192.168.183.254, port2
S 2.0.0.0/8 [10/0] via 192.168.183.254, port2
C 10.142.0.0/23 is directly connected, port3
B 10.160.0.0/23 [20/0] via 10.142.0.74, port3, 2d18h02m
C 192.168.182.0/23 is directly connected, port2
```

Examining an entry from the routing table above:

```
B 10.160.0.0/23 [20/0] via 10.142.0.74, port3, 2d18h02m
```

B	BGP. The routing protocol used.
10.160.0.0/23	The destination of this route including netmask.
[20/0]	20 indicates and administrative distance of 20 out of a range of 0 to 255. 0 is an additional metric associated with this route, such as in OSPF
10.142.0.74	The gateway, or next hop.
port3	The interface used by this route.
2d18h02m	How old this route is, in this case almost three days old.

Perform a sniffer trace

When troubleshooting network traffic, it helps to look inside the headers of packets to determine if they are traveling along the route you expect. Packet sniffing can also be called a network tap, packet capture, or logic analyzing.

If your Carrier-enabled FortiGate unit has NP interfaces that are offloading traffic, this will change the sniffer trace. Before performing a trace on any NP interfaces, disable offloading on those interfaces.

What can sniffing packets tell you

If you are running a constant traffic application such as ping, packet sniffing can tell you if the traffic is reaching the destination, what the port of entry is on the Carrier-enabled FortiGate unit, if the ARP resolution is correct, and if the traffic is being sent back to the source as expected.

Sniffing packets can also tell you if the Carrier-enabled FortiGate unit is silently dropping packets for reasons such as RPF (Reverse Path Forwarding), also called Anti Spoofing. This prevents an IP packet from being forwarded if its source IP address either does not belong to a locally attached subnet (local interface), or be a hop on the routing between the FortiOS Carrier and another source (static route, RIP, OSPF, BGP). Note that RPF can be disabled by turning on asymmetric routing in the CLI (`config system setting, set asymmetric enable`), however this will disable stateful inspection on the Carrier-enabled FortiGate unit and consequently cause many features to be turned off.

If you configure virtual IP addresses on your Carrier-enabled FortiGate unit, the unit will use those addresses in preference to the physical IP addresses. If not configured properly, secondary IP addresses can cause a broadcast storm. You will notice the secondary address being preferred when you are sniffing packets because all the traffic will be using the virtual IP addresses. This is due to the ARP update that is sent out when the VIP address is configured.

How to sniff packets

The general form of the internal FortiOS packet sniffer command is:

```
diag sniffer packet <interface_name> <'filter'> <verbose> <count>
```

To stop the sniffer, type `CTRL+C`.

<interface_name>	The name of the interface to sniff, such as `port1` or `internal`. This can also be `any` to sniff all interfaces.
<'filter'>	What to look for in the information the sniffer reads. `none` indicates no filtering, and all packets will be displayed as the other arguments indicate. The filter must be inside single quotes (‘).
<verbose>	The level of verbosity as one of: **1 -** print header of packets **2 -** print header and data from IP of packets **3 -** print header and data from Ethernet of packets
<count>	The number of packets the sniffer reads before stopping. If you don't put a number here, the sniffer will run forever unit you stop it with `<CTRL C>`.

For a simple sniffing example, enter the CLI command `diag sniffer packet port1 none 1 3`. This will display the next 3 packets on the port1 interface using no filtering, and using verbose level 1. At this verbosity level you can see the source IP and port, the destination IP and port, action (such as ack), and sequence numbers.

In the output below, port 443 indicates these are HTTPS packets, and 172.20.120.17 is both sending and receiving traffic.

```
Head_Office_620b # diag sniffer packet port1 none 1 3
interfaces=[port1]
filters=[none]
0.545306 172.20.120.17.52989 -> 172.20.120.141.443: psh 3177924955 ack 1854307757

0.545963 172.20.120.141.443 -> 172.20.120.17.52989: psh 1854307757 ack 3177925808

0.562409 172.20.120.17.52988 -> 172.20.120.141.443: psh 4225311614 ack 3314279933
```

Generate specific packets to test the network

If some packets are being delivered as expected while others are not, or after you believe you have fixed the problem, it is a good idea to generate specific traffic to test your network.

For example if you discover through log messages and packet sniffing that Create PDP Context Request messages are not being delivered between two SGSNs, you can generate those specific messages on your network to confirm they are the problem, and later that you have solved the problem and they are now being delivered as expected.

This step requires a third party traffic generation tool, either hardware or software. This is not be supported by Fortinet.

Chapter 9 - PCI DSS Compliance

Compliance

This FortiOS Handbook chapter contains the following sections:

Configuring FortiGate units for PCI DSS compliance on page 1025 explains the Payment Card Industry Data Security Standard (PCI DSS). It provides information about configuring your network and FortiGate unit to help you comply with PCI DSS requirements.

FortiOS 5.4 PCI DSS compliance new features

Vulnerability Scanning has been removed (293156)

Vulnerability scanning can now be done from FortiClient.

PCI DSS Compliance Check Support (270014)

FortiOS 5.4 allows you to run a compliance check either on demand or according to a schedule that automatically checks PCI DSS compliance at the global or VDOM level. The compliance check determines whether the FortiGate is compliant with each PCI DSS requirement by displaying an 'X' next to the non-compliant entries in the GUI logs.

Go to **System > Advanced > Compliance**, turn on compliance checking and configure a daily time to run the compliance check. Or you can select **Run Now** to run the compliance check on demand.

Go to **Log & Report > Compliance Events** to view compliance checking log messages that show the results of running compliance checks.

Configuring FortiGate units for PCI DSS compliance

This chapter provides information about configuring your network and FortiGate unit to help you comply with PCI DSS requirements. There is also some description of other Fortinet products that can help you with PCI DSS compliance.

Introduction to PCI DSS

The primary source of information for your PCI DSS compliance program is the Payment Card Industry (PCI) Data Security Standard itself. Version 3.1 of the standard was published in April 2015. The following is a brief summary of PCI DSS.

What is PCI DSS?

The Payment Card Industry Data Security Standard (PCI DSS) sets data handling requirements for organizations that hold, process, or exchange cardholder information.

What is the Cardholder Data Environment

Throughout the PCI DSS requirements, there are references to the Cardholder Data Environment (CDE). The CDE is the computer environment wherein cardholder data is transferred, processed, or stored, and any networks or devices directly connected to that environment.

PCI DSS objectives and requirements

PCI DSS consists of 7 control objectives and 12 requirements.

PCI DSS Control Objectives and Requirements

Control Objective	Requirement	Fortinet Solution
Build and Maintain a Secure Network and Systems	**1.** Install and maintain a firewall configuration to protect cardholder data	FortiGate firewall functionality. See Security policies for the CDE network on page 1031
	2. Do not use vendor - supplied defaults for system passwords and other security parameters	FortiDB vulnerability assessment and auditing FortiWeb web application password checking See Password complexity and change requirements on page 1037

Control Objective	Requirement	Fortinet Solution
Protect Cardholder Data	**3.** Protect stored cardholder data	FortiDB vulnerability assessment and monitoring FortiWeb web application firewall See Protecting stored cardholder data on page 1034
	4. Encrypt transmission of cardholder data across open, public networks	FortiGate IPsec VPN. See Protecting communicated cardholder data on page 1034
Maintain a Vulnerability Management Program	**5.** Protect all systems against malware and regularly update antivirus software or programs	FortiGate integrated AV FortiClient integrated AV FortiMobile integrated AV FortiMail integrated AV FortiGuard automated AV updates See Protecting the CDE network from viruses on page 1035
	6. Develop and maintain secure systems and applications	FortiDB vulnerability assessment, auditing and monitoring FortiWeb web application security FortiGate Application Control
Implement Strong Access Control Measures	**7.** Restrict access to cardholder data by business need-to-know	FortiDB vulnerability assessment, auditing and monitoring. See Restricting access to cardholder data on page 1036
	8. Identify and authenticate access to system components	FortiGate integrated database or hooks to Active Directory. See Controlling access to the CDE network on page 1037
	9. Restrict physical access to cardholder data	Fortinet professional services in partnership with partner solutions

Control Objective	Requirement	Fortinet Solution
Regularly Monitor and Test Networks	**10.** Track and monitor all access to network resources and cardholder data	FortiDB auditing and monitoring FortiAnalyzer event reporting See Monitoring the network for vulnerabilities.
	11. Regularly test security systems and processes	FortiDB vulnerability assessment See Monitoring the network for vulnerabilities.
Maintain an Information Security Policy	**12.** Maintain a policy that addresses information security for all personnel	FortiManager security policy management appliance

This chapter describes how the FortiGate's features can help your organization to be compliant with PCI DSS. Requirements that the FortiGate cannot enforce need to be met through organization policies with some means determined for auditing compliance.

Be sure to read the following wireless guidelines. Even if your organization does not use wireless networking, PCI DSS requires you to verify periodically that wireless networking has not been introduced into the CDE.

Wireless guidelines

While wired networks usually connect fixed known workstations, wireless networks are more dynamic, introducing a different set of security concerns.

Even if your organization does not use wireless networking, PCI DSS requires you to verify periodically that unauthorized wireless networking has not been introduced into the CDE. Wireless networking could be introduced quite casually by adding a wireless device to a PC on the CDE network.

For all PCI DSS networks, whether they use wireless technology or not, the following requirement applies:

- Test for the presence of wireless access points by using a wireless analyzer at least quarterly or deploying a wireless IDS/IPS to identify all wireless devices in use. (11.1)

If your organization uses wireless networking outside the CDE network and the firewall prevents communication with the CDE network, the wireless network is outside the PCI DSS scope, but the firewall configuration must meet PCI DSS requirements.

If your organization uses wireless networking inside the CDE network, the wireless network is within the PCI DSS scope. For information about wireless network requirements, see Wireless network security on page 1032.

Running PCI DSS compliance checks

FortiOS 5.4 allows you to run a compliance check either on demand or according to a schedule that automatically checks PCI DSS compliance at the global and/or VDOM level. The compliance check determines whether the FortiGate is compliant with each PCI DSS requirement by displaying an 'X' next to the non-compliant entries in the GUI logs.

The FortiGate runs at least 50 compliance checks that report on the status of a number of things including:

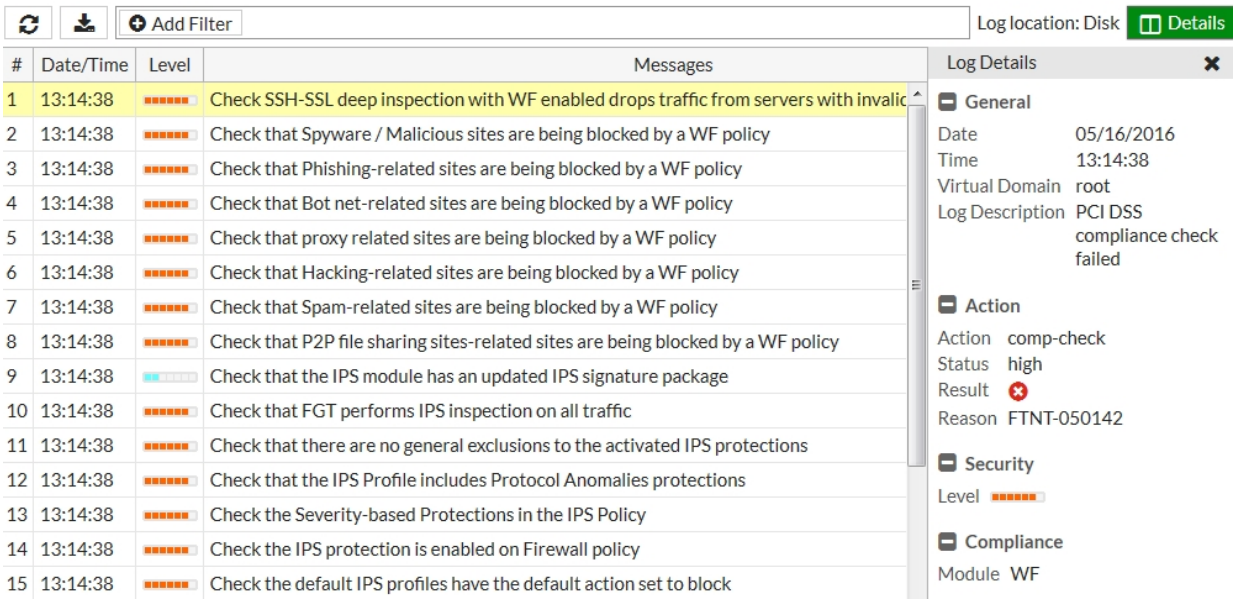
- Checking that out of stet ICMP packets are dropped
- The TCP end timeout is set
- SSH and SSL deep inspection with web filtering drops traffic from servers with invalid server certificates
- Verifying that IPS signatures, Application Control signatures, and Antivirus signatures are up to date
- Determining if Spyware/Malicious sites are being blocked by a web filtering policy
- Verifying that administrators are locked out after 3 login failures

For a complete list of compliance checks go to **Log & Report > Compliance Events**.

Configuring PCI DSS compliance checking

Go to **System > Advanced > Compliance**, turn on compliance checking and configure a daily time to run the compliance check. Or you can select **Run Now** to run the compliance check on demand.

Go to **Log & Report > Compliance Events** to view compliance checking log messages that show the results of running compliance checks.



You can also configure compliance checking and set up the schedule from the CLI:

```
config system global
   set compliance-check {disable| enable}
   set compliance-check-time <time>
end
```

Use the following command to run on-demand compliance checking:

```
execute dsscc
```

Per-VDOM compliance checking

If you have multiple VDOMs enabled compliance checking can be run separately for each VDOM.

Begin from the Global view by going to **System > Advanced > Compliance** and turning on compliance checking and configuring a daily time to run the compliance check. This compliance check daily schedule will be used to run compliance checks on individual VDOMs where compliance checking is enabled them.

You can also enable global compliance checking from the CLI:

```
config global
   config system global
      set compliance-check {disable| enable}
      set compliance-check-time <time>
   end
```

Then log onto each VDOM for which to enable compliance checking and go to to **System > Advanced > Compliance**, and turn on compliance checking . You can also select **Run Now** to run a compliance check on that VDOM on demand.

From the CLI edit a VDOM and use the following command to enable compliance checking for that VDOM. The following example shows how to enable compliance checking for the root VDOM:

```
config vdom
   edit root
      config system settings
         set compliance-check enable
      end
```

From the CLI you can also log into a VDOM and use the following command to run on-demand compliance checking:

```
execute dssccc
```

From a VDOM GUI go to **Log & Report > Compliance Events** to view compliance checking log messages that show the results of running compliance checks.

Compliance checking diagnose command

Use the following command to display diagnostic information about compliance checking:

```
diagnose debug application dssccd <debug_level>
```

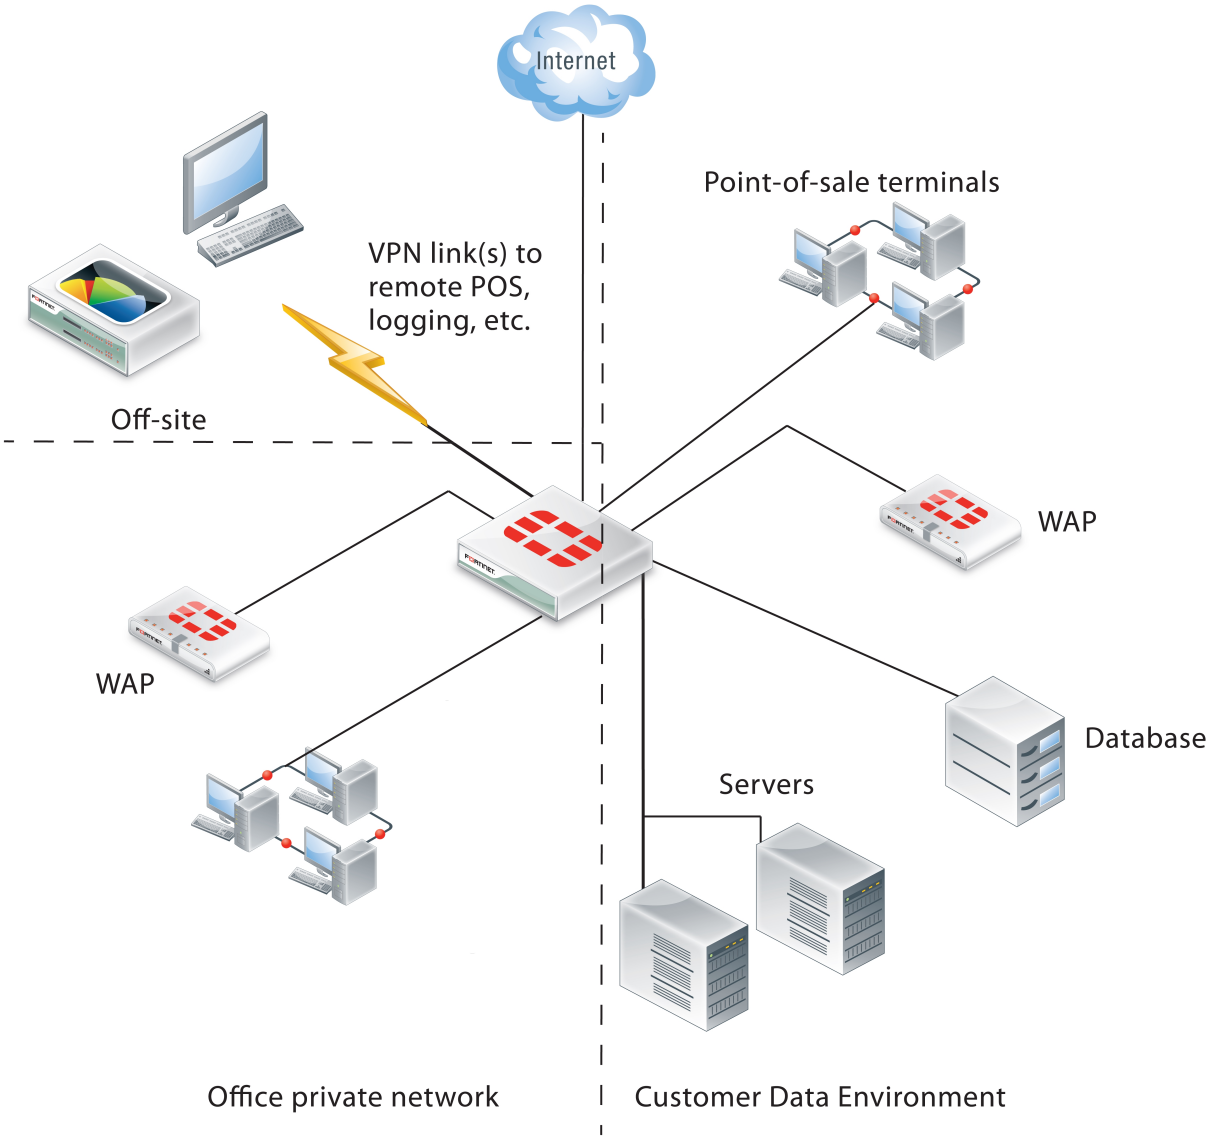
Network topology

The cardholder data environment must be protected against unauthorized access from the Internet and from other networks in your organization. FortiGate unit firewall functionality provides tight control over the traffic that can pass between the following network interfaces:

- Internet
- CDE wired LAN
- CDE wireless LAN
- Other internal networks

The figure below shows how the Cardholder Data Environment can be delineated in a typical network.

Enterprise network with a cardholder data environment



Internet

The FortiGate unit has at least one network interface connected to the Internet. If your organization uses more than one Internet service provider, there could be additional network interfaces that function as a route to the Internet.

The CDE wired LAN

The CDE network typically contains point-of-sale (POS) terminals, databases, and servers. The only security policies between the CDE network and the Internet should be for encrypted connections. For remote point-of-sale terminals or off-site databases, VPN connections are required and they should use strong encryption. For a web server that handles online purchases, only HTTPS (SSL or TLS) connections can be permitted. The security

policies that enable these connections should have the narrowest possible definitions for source address, destination address and service.

PCI DSS does not require the CDE network to be isolated from the rest of your corporate LAN. But isolating the CDE network reduces the scope of required data protection measures and may reduce the scope of PCI DSS assessments that are periodically required.

The CDE wireless LAN

Wireless networking is a special issue. Even if you do not use wireless technology you must monitor to ensure that unauthorized wireless access has not been added to the CDE network. For this purpose, the figure above shows a FortiAP device in the CDE. The FortiAP device can provide dedicated wireless monitoring, an access point, or both.

A small retail outlet could reduce costs by using a FortiWiFi unit, a FortiGate unit with integrated wireless networking. The FortiWiFi unit would have to be located where it could provide sufficient wireless monitoring (or access point) coverage for the entire premises.

Other internal networks

Other internal networks such as your office LAN, unless they provide connection to the CDE, are not subject to PCI DSS requirements.

Security policies for the CDE network

The FortiGate unit's firewall functionality is ideally suited to PCI DSS requirement 1.2.1, "Restrict inbound and outbound traffic to that which is necessary for the cardholder data environment, and specifically deny all other traffic." Security policies control the source, destination, and type of traffic passing between networks.

The PCI DSS standard includes requirements to document your network topology and configuration. As part of that requirement, and to assist the auditing of your network, make use of the **Comment** field available in FortiGate security policies. Describe the purpose of each policy.

Controlling the source and destination of traffic

The source and destination are the first parameters you specify in a security policy. (Go to **Policy & Objects > IPv4 Policy** and select **Create New**.)

The **Interface** settings depend on network topology. The **Source** and **Destination Address**settings define the IP addresses to which the policy applies. These should be as narrow as possible, so that only the appropriate hosts are included. For example, if the destination is a server with a single IP address, the named **Destination Address** should be defined as that single address, not the entire subnet on which the server resides.

Addresses are defined in **Policy & Objects > Addresses**. Some addresses will be used in several security policies, so it is best to plan ahead and define the addresses first.

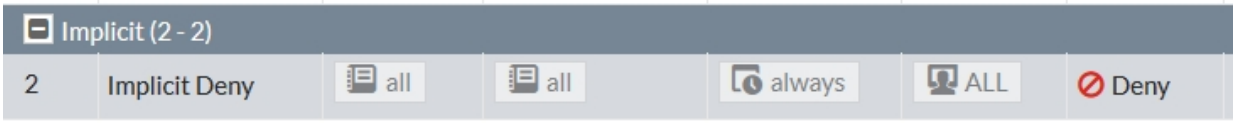
Controlling the types of traffic in the CDE

The **Policy & Objects > Service** setting determines which types of traffic can pass based on protocol.

You can select a single protocol from the **Service** drop-down list. To add another protocol, select the green "+" button to access the **Service** drop-down list again. If several security policies will need the same list of services, consider creating a named service group. (Go to **Firewall Objects > Service > Groups**.) In the security policy, service groups are available at the bottom of the **Service** drop-down list.

The default deny policy

All traffic not specifically allowed by a security policy that you create is blocked by the Implicit policy listed at the bottom of the **Policy & Objects > IPv4 Policy** page.



You cannot delete this policy and you can edit the policy only to enable or disable logging of the traffic that it handles.

Wireless network security

Scanning for rogue access points is the minimum requirement for wireless security. Even if your organization does not use wireless networking, PCI DSS requires you to verify periodically that wireless networking has not been introduced into the CDE.

If you use wireless networking, the wireless network is only within the PCI DSS scope if it can connect to the CDE.

On-wire detection of rogue APs

FortiGate units include an "on-wire" detection technique that correlates the SSID MAC addresses of the unknown access points with MAC addresses detected on your wired networks. This helps to differentiate unrelated neighboring APs from security-compromising unauthorized APs connected to your network.

Setting up rogue access point scanning

A FortiGate unit with a connected FortiAP unit can perform wireless scanning. Each of the FortiAP radios can act as a dedicated monitor or can perform scanning in the background while acting as a wireless access point.

Radio 1 operates in the 2.4GHz band and Radio 2 operates in the 5GHz band. Both bands should be monitored. The FortiAP unit(s) used for scanning must be located within the coverage area that would result if an access point were added to the CDE.

To configure rogue AP scanning in a FortiAP profile

1. Go to **WiFi & Switch Controller > WIDS Profiles**.
   On some models, the menu is **WiFi & Switch Controller**.
2. Select an existing WIDS profile and edit it, or select **Create New**.
3. Make sure that **Enable Rogue AP Detection** is selected.

4. Select **Enable On-Wire Rogue AP Detection**.
5. Optionally, enable **Auto Suppress Rogue APs in Foreground Scan**.
6. Select **OK**.

Viewing the results of rogue AP scanning

Go to **Monitor > Rogue AP Monitor** to view information about detected rogue wireless access points.

Logging the results of rogue AP scanning

To ensure that detection of rogue access points is logged, go to **Log & Report > Log Settings**, enable **Event Logging** and select **WiFi activity event**.

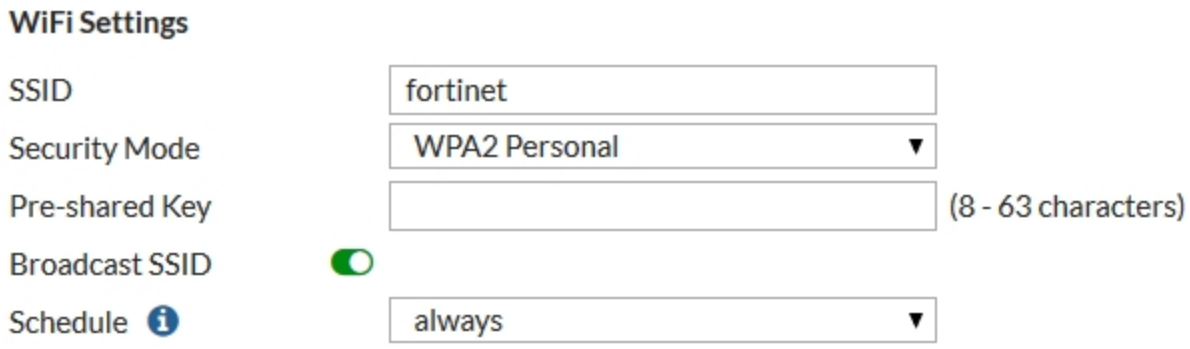
Securing a CDE network wireless access point

If your wireless network is within PCI DSS scope, it must meet the following requirements:

- Default settings such as SSID and passphrases must be changed.
- Use WPA/WPA2 security.
- Log wireless activity.

Setting wireless security

On FortiGate units, go to **WiFi & Switch Controller > SSID** to configure wireless security settings for either a new or existing virtual access point.



The default SSID for the FortiAP is “fortinet”. You must change this.

The **Security Mode** must be set to one of the WPA2 modes. Both WPA or WPA2 clients can be served. In the CLI, you can optionally select exclusively WPA or WPA2 operation.

WPA/WPA2-Enterprise **Authentication** uses separate logon credentials for each user. Either FortiGate user group security or an external RADIUS server performs the authentication. Optionally, certificate-based security can also be applied. WPA/WPA2-Personal authentication requires a single pre-shared key that is used by all clients and is thus less secure.

For detailed information about wireless access points, see the Deploying Wireless Networks chapter of the FortiOS Handbook.

Logging wireless network activity

To ensure that wireless network actiity is logged, go to **Log & Report > Log Settings**, enable **Event Logging** and select **WiFi activity event**.

Protecting stored cardholder data

The Fortinet FortiDB and FortiWeb products can provide security for your sensitive cardholder data.

The Fortinet Database Security (FortiDB) device provides vulnerability assessment, database activity monitoring, auditing and monitoring.

The Fortinet FortiWeb Web Application Firewall deployed in front of public-facing web applications protects Web applications, databases, and the information exchanged between them. In particular, it addresses the PCI DSS requirements 6.5 and 6.6 regarding web application vulnerabilities such as cross-site scripting, SQL injection, and information leakage.

FortiGates support some web application firewall security features and allow you to offload selected HTTP and HTTPS traffic to an external FortiWeb device. To offload HTTP traffic to go **System > Cooperative Security Fabric,** enable **HTTP service** and select FortiWeb.

Protecting communicated cardholder data

If cardholder data must be communicated over an untrusted network, such as the Internet, use the FortiGate unit's IPsec VPN capability to exchange the data securely. If you support customer online transactions, use HTTPS (SSL or TLS encryption) for security. The relevant PCI DSS requirement is:

- Use strong cryptography and security protocols (for example, SSL/TLS, IPSEC, SSH, etc.) to safeguard sensitive cardholder data during transmission over open, public networks. (4.1)

This does not prescribe particular cryptography, but it can be interpreted as a requirement to follow industry best practices.

Configuring IPsec VPN security

The security considerations for IPsec VPNs are encryption and authentication.

Encryption

Go to **VPN > IPsec Tunnels** to configure an IPsec VPN. In both Phase 1 and Phase 2 parts of the configuration, you select the encryption to use.
